ARISTOPHANES of Byzantium, the founder of the Alexandrian Critical School, who is said to have invented the system of Greek accents and method of punctuation. He was the master of Aristarchus the grammarian. He flourished in the reign of Ptolemy Epiphanes, about 200 years B.C., and was the author of several exegetical and grammatical works which are lost.

ARISTOTLE.

Aristotle.

The power of philosophy in fixing an impression of itself on the world, appears, when attentively viewed, no less than that evidenced in successful exertions of civil or military talents. But there is a striking difference in the comparative interest excited by the philosopher himself, and by the distinguished statesman or general. The personal fortunes of the philosopher are not connected with the effects of his philosophy. He has passed away from the eyes of men, when his powerful agency begins to be perceived; whereas the statesman and the commander of armies are at once set before us in the very effects which they produce on the world; and the history which tells of their policy or their conquests assumes almost the character of their biographies.

This contrast is strongly displayed in the instance of the particular philosopher whose life we would now retrace. At this day, after the lapse of more than twenty-one centuries from the time when he flourished, we are experiencing the power of Aristotle's philosophy, in its effects on language and literature and science, and even on theology; and yet little satisfactory information can be obtained from antiquity respecting the philosopher himself. No account of him appears to have been given until his celebrity had attracted envy as well as admiration; so that we are compelled to receive with suspicion every thing beyond the simple detail of a few facts.

Stagirus,[1] a Grecian city in the peninsula of Chalcidice, colonized originally from the island of Andros, and afterwards from Chalcis in Eubœa, was the birthplace of Aristotle. His father was Nicomachus, the physician and friend of Amyntas II. king of Macedonia; his mother Phæstis: both of Chalcidian descent. The origin of his family is referred to Machaon, son of Æsculapius. Such a tradition of descent, however, is but an ennobling of the fact that the art of healing was the hereditary profession of the family.[2] The date assigned to his birth is B.C. 384.

Being left an orphan in early youth, Aristotle appears to have quitted his home and gone to the house of Proxenus, a citizen of Atarneus, to whose guardianship he had been committed; and with him to have continued until his seventeenth year, when he repaired to the great University of the world at that time—the school of Plato at Athens. Different accounts are given of the commencement of his application to philosophy. By one it is ascribed to a direction of the Pythian oracle.[3] Others state that philosophy was his last resource, when other schemes of life had failed; that, having exhausted a large patrimony, he became a military adventurer, and after that a seller of drugs; until at length, on accidentally entering the school of Plato, he there received a sudden impulse to the studies of his future life. These last statements, however, are not reconcilable with the period of youth at which his discipleship to Plato began. Nor are they consistent with the alleged fact, that his mind had been from the first trained to philosophy by his father Nicomachus.[4]

We can readily suppose that the extraordinary talent for science, and laborious devotion to it, which his mature age developed, would give some indications of themselves in his earlier years. Hence the expressions attributed to Plato, complimenting him as "the intellect of the school," and "the reader," and comparing his ardour and forwardness to the spirit of a restive colt.[5]

Aristotle.

He remained at Athens, a hearer of Plato, twenty years; leaving it only at the death of that philosopher, B.C. 348, and then going to Atarneus. Disappointment at not succeeding to the chair of Plato in the Academy, has been assigned as the reason of his departure. All that appears, however, is, that he left Athens in compliance with an invitation from Hermias,[6] who, having been his fellow-disciple in the school of Plato, had established himself at that time in independence against the King of Persia, as Tyrant of Atarneus and its neighbourhood. Here he spent the following three years of his life; when the unhappy end of his friend Hermias, who fell a sacrifice to his ambition, and was executed as a rebel against Persia, compelled him to seek a refuge for himself by flight to Mitylene. Nor did he in this extremity forget the ties of friendship which had connected him with the unfortunate Tyrant of Atarneus. To support the fallen family, he married Pythias, the adopted daughter, but variously described both as the sister and as the niece,[7] of Hermias.

From Mitylene he proceeded into Macedonia to the court of Philip, and entered on a new scene of exertion, as the preceptor of the future sovereign of the mightiest kingdom of the ancient world—Alexander the Great, at that time a youth of fourteen years of age. The call to such an office argues the high reputation already attained by Aristotle for philosophy; though, doubtless, his introduction to the Macedonian court must have been through the interest and favour enjoyed there by his father Nicomachus. At what time, indeed, his care of the youthful prince commenced, it is not possible exactly to determine. A letter is extant, addressed by Philip to Aristotle, which would imply that the charge of the prince's education had been committed to the philosopher from the birth of Alexander. This is also far more probable than that the charge should have been postponed until the prince had reached his fourteenth year, the period at which the actual residence of Aristotle at Pella is dated. Philip states in that letter that "a son is born to him; that he is grateful to the gods, but not so much for the birth of the boy, as that he was born in the time of Aristotle; trusting that, being nurtured and trained up by the philosopher, he would be a worthy successor to his father's glory and the conduct of affairs."[8] It is certainly very possible that a plan of education proposed by Aristotle may have been carried on by others, until the more especial care of the intellectual powers demanded his personal instructions. The reception of the philosopher by the royal family was most friendly and honourable to him. The high estimation in which he was held was shewn in the influence he possessed at the Macedonian court. Philip, it is said, gave him liberal supplies of money to enable him to pursue scientific inquiries.[9] He was most happy in the admiration and affection of his pupil. Alexander valued his instructions as those of a second parent; observing, that "he was no less indebted to Aristotle than to his father; since it was

[6] Commonly called Hermias the eunuch.

[7] Aristippus, according to Laertius, says it was the mistress of Hermias that Aristotle married.

[8] Aulus Gellius, *Noct. Att.* ix. 3. The genuineness of the letter has been doubted, but without sufficient reason, if the only ground of objection is, that it could not have been received by Aristotle at Mitylene.

[9] Ælian. *Var. Hist.* iv. 19. The statement of Hermippus (Diog. Laert. in *Aristot.*), that Aristotle served in the capacity of ambassador from the Athenians to Philip, seems inconsistent with other established facts of his life.

Aristotle.

through his father indeed that he lived, but through Aristotle that he lived well."[1]

It would be interesting to know what particular method was pursued by Aristotle in the education of Alexander; but we have no exact information on this point. It appears certain, however, that he made the cultivation of a taste for literature the great principle of his instructions: and this would be in conformity with the plan of education proposed in his treatise of Politics. He is known, indeed, to have made a new collection of the Iliad expressly for the use of Alexander, and to have composed for him a treatise *On the Office of a King*, not extant among his works. How deeply the youthful king had imbibed the Homeric spirit in the discipline of his early years, was evidenced in his after-life, by the heroism with which his actions were conceived, and the poetry which mingled with the realities of his eventful history. The circumstances alone, that the Iliad was constantly at the pillow of Alexander during his expeditions, and was treasured by him with extraordinary care in the precious casket of the spoils of Darius,[2] are characteristic of the tone of mind which his preceptor's instructions had, if not formed, at least strengthened and improved. Nor is it inconsistent with this ultimate effect, that Aristotle should have communicated to his royal pupil even the abstruse doctrines of his philosophy. For, that he did so, we have evidence in Alexander's complaint, in a letter to Aristotle, of the publication of the secret wisdom in which he had himself been disciplined; and in the reply from Aristotle, "that the books alluded to were as if they had not been published, since without his oral instruction they would be unintelligible."[3] Plutarch, indeed, attributes to Aristotle's instructions the fondness for medical study and practice remarkable in Alexander.[4]

A life of such premature exertion as that of Alexander left comparatively little time for the mere business of philosophical instruction. Succeeding to the throne of his father at the age of 20 years, he was from that time immersed in affairs of policy and war; and even previously, he had been forwardly engaged in the services of the field, as also for a short interval in the conduct of the government. Still the society of Aristotle appears to have been cherished by him, so that the philosopher continued a resident at the court for two years after the accession of Alexander; leaving Macedonia only on the occasion of Alexander's setting out on his Asiatic campaigns, B.C. 334.[5] It is probable that Aristotle was indisposed to the hurry and restlessness of military expeditions, and longed for a repose more congenial to his taste in the philosophic bowers of the suburbs of Athens. Circumstances also had prepared the way for the separation. For though Alexander, it seems, never entirely lost his respect for his preceptor, the cordiality of their intercourse had in some measure abated. A commencement of alienation in the feelings of Alexander had been evidenced.[6] Aristotle, accordingly, embraced the opportunity then offered of returning to Athens: and Callisthenes of Olynthus, his relative and pupil, supplied his place among the party of philosophers by whom the king was accompanied in the Asiatic expedition.

It was fortunate for science that the intercourse between the King and the philosopher was not broken off by their separation. The conquests of Alexander presented singular opportunities for a collection of observations on Natural History. Under the superintendence, accordingly, of Aristotle some thousands of persons, it is said, were employed in making inquiries on the subject throughout Asia and in Greece. And we have still valuable fruits of these inquiries, in a *History of Animals*, in ten books, extant among the works of Aristotle; though this history must be but a small part of the fifty volumes to which Pliny says it extended.[7]

In the absence, however, of Aristotle, an event occurred which had the effect of exciting most unjust surmises against him, and involving him in unmerited disgrace with Alexander. A conspiracy was formed against the life of the king by some noble youths who attended on his person. The conspirators were detected and punished. But the chief blame of the whole affair rested on Callisthenes; to whom the education of the youths had been especially committed, and under whose sanction, accordingly, they were conceived to have acted in their traitorous designs. The imputation was the more credible, as Callisthenes had distinguished himself by his opposition to the adulation of the courtiers, and the rude freedom with which, in spite of the admonitions of Aristotle,[8] he asserted his democratic principles. How far he was really guilty may admit a doubt. A pretext at least was afforded for the removal of an obnoxious individual. Callisthenes was imprisoned, and died a violent death. His connection with Aristotle gave a plea for extending the charge to Aristotle himself; who, it is represented, became so fearful of the result to himself, after the death of Callisthenes, as to have been actually instrumental to the murder of the King. He is stated to have sent a very subtle poison, called Stygian water, in a mule's hoof, the only material impregnable to it, to Antipater, and thus to have occasioned the death of the King.[9] The account is sufficiently refuted by the real state of the case, which shews that Alexander fell a sacrifice to his intense exertions in an unhealthy climate. It was probably invented and propagated by the rival sophists who surrounded the person of Alexander. To the same source may be ascribed the first estrangement of the King, and his increased aversion to the philosopher in consequence of the affair of Callisthenes. Alexander pointedly shewed his increased dislike, by sending a present of money to Xenocrates; thus placing that philosopher, as well as Anaximenes, whom he also now more particularly noticed, in triumphant contrast with Aristotle, as the objects of his patronage.[10]

In the mean time Aristotle was pursuing his proper path of exertion at Athens as a lecturer in philosophy, in his own school of the Lyceum. There is no good reason for supposing that he was actuated in forming a separate school, as some

---

1 Plutarch in *Alex.* Diog. Laertius in *Aristot.* attributes to Aristotle himself a general expression to the same effect.

2 Plutarch in *Alex.* whence it obtained the name of "the Iliad," εκ του ναρθηκος, "of the casket."

3 Plutarch in *Alex.* Aulus Gellius, *Noct. Att.* xx. 5. This literary jealousy on the part of Alexander appears also from a passage of Aristotle, where, writing to Alexander (*Rhet. ad Alex.* 1), (if the treatise here referred to be really his), he says "you have charged me in your letter that no other person should receive this book."

4 Plutarch in *Alex.*

5 Ammonius, in his *Life of Aristotle*, asserts that Aristotle accompanied Alexander into Asia, and conferred with the Brahmans, where he composed "the two hundred and fifty Polities." How much credit may be attached to this author, appears from his making Aristotle a disciple of Socrates for three years, whereas Socrates had been dead sixteen years before the birth of Aristotle.

6 Plutarch in *Alex.*

7 Plin. viii. 16.

8 Aristotle is said expressly to have cautioned Callisthenes in the words of Thetis to Achilles (*Iliad*, xviii. 95):

Ωκυμορος δη μοι, τεκος, εσσεαι, δι' αγορευεις.

"Quick, indeed, for me, will be thy fate, my son, if such are thy words."

And generally to have admonished him to converse, either very seldom, or else most complaisantly, with the king. Valer. Maxim. vii. 2. Diog. Laert. in *Aristot.*

9 Arrian. *Exp. Alex.* vii. 27.; Plin. xxx. 16; Xiphilin. in *Caracalla*; Qu. Curtius, viii. 6; Brucker, *Hist. Crit. Philos.* in *Aristot.*

have asserted, by contemptuous opposition to Xenocrates, or jealousy of the rhetorical fame of Isocrates.[1] His own fame already stood sufficiently high. Numbers resorted to him for instruction. In the morning and evening of each day he was thronged with hearers; the morning class consisting of his more intimate and peculiar disciples, the evening class of hearers of a more general description. The distinction of these two classes corresponds with the difference between his "acroamatic" or "esoteric" and his "exoteric" philosophy. The application of these terms to the writings of Aristotle has been much controverted. The most simple account of them appears to be, that the acroamatic or esoteric were more of text-books, notices of various points of philosophy to be filled up by the previous knowledge of the learner and the explanations of the teacher, as lectures addressed to his own proper class; the exoteric were more elaborate and popular disquisitions, more expanded in the reasonings, more diffuse in the matter.[2] His disciples obtained the appellation of Peripatetics; but the reason of this is also controverted. Perhaps, like some other party-names, or names of sects, it was originally given in contempt.[3]

The reputation of Aristotle at length rose to a dangerous popularity. The intolerant spirit of paganism viewed with suspicion the spread of philosophical teaching, as tending to unsettle the existing government through their effect on the vulgar superstition. This had been strikingly shown at Athens not long before the birth of Aristotle in the fate of Socrates.[4] In the case of Aristotle there were enemies watching to apply the policy of the state to the cruel purposes which their envy had suggested. For twelve years, it seems, no opportunity of attack presented itself; since he continued his labours at Athens for that time. Probably the name of Alexander had been itself a shelter to him against their malice. But the alienation of the royal favour gave an opening to their designs; and, on the death of Alexander, B.C. 323, he became the marked object of persecution. Through the agency of the hierophant Eurymedon, with whom was associated a powerful citizen, by name Demophilus, a direct accusation of impiety was brought against him before the court of Areopagus. He was charged with introducing doctrines adverse to the religion of Greece.[5] It was alleged that he had paid divine honours both to Hermias and Pythias; to the former by a hymn in praise of his virtue, to the latter by celebrating her memory (for she was then dead) with the Eleusinian rites,[6] and to both by statues of them erected at Delphi. He saw that he had no chance of a favourable hearing against so formidable a conspiracy, and that his death was fully determined by his enemies; knowing too well the malignant sycophancy[7] which domineered at Athens. Instead, therefore, of confronting the charge, he made his escape to Chalcis, alleging to his friends, in allusion to the death of Socrates, "that he was unwilling to involve the Athenians in a second crime against philosophy."[8]

He did not long survive his retreat to Chalcis—little more, probably, than a year. He was then advanced in life, and broken with bodily infirmities as well as with dejection of spirit. On the approach of death, he declared his wish, it is said, with regard to his successor at the Lyceum. Theophrastus of Lesbos and Menedemus of Rhodes were the most conspicuous candidates for that honour. But the dying philosopher, avoiding a pointed rejection of either, delicately intimated his preference of Theophrastus, by calling for cups of Lesbian and Rhodian wine, and, when he had tasted them, simply observing, ἡδίων ὁ Λέσβιος, "*The sweeter is the Lesbian.*"[9] The expression was the more appropriate, as sweetness was the characteristic of the style of Theophrastus.

The mode of his death is variously related. One account is, that he died from vexation at not being able to explain the current of the Euripus.[10] Another story, less incredible than this, asserts that he drank aconite, in anticipation of the adverse judgment of the Areopagus.[11] The only probable account is, that he died from a natural decay of the powers of the stomach, his constitution being worn out by excessive watching and study. How exhaustless his application of mind was, may be judged from the anecdote related of him, that in resting himself on his couch, he would hold a brass ball in his hand in such a way, that the noise of its falling into a basin underneath might disturb him from his slumbers.[12] Another anecdote to the same effect is, that on some occasion of sickness, he observed to the physician prescribing for him, "Treat me not as you would a driver of oxen or a digger, but tell me the cause, and you will find me obedient."[13]

His fellow-citizens showed great respect to his memory. They conveyed his body to *Stagirus*, and erected a shrine and altar over his tomb. In gratitude also for the restoration of their city, effected through his interest with the Macedonian court, and the new code of laws which he had been permitted to frame for them, they instituted a festival called Aristotelea, and gave the name of Stagirite to the month in which the festival was held. Plutarch says that even in his time they showed the stone seats and shaded walks of the philosopher.[14] The grant of a gymnasium had been among the advantages which he had obtained for his native city.

Aristotle was twice married. After the death of Pythias, by whom he had a daughter of the same name, he married Herpyllis, a fellow-citizen. By Herpyllis he had a son, Nicomachus, who became a disciple of Theophrastus, but died in battle at an early age.[15] He adopted also as a son, Nicanor, the son of Proxenus, the friend of his youth, and by the directions of his will gave his daughter Pythias to him in marriage. Pythias, by her third husband Metrodorus, had a son named after the philosopher.

In his extant will we have a pleasing evidence of his amiable concern for his surviving family. It contains affectionate provisions, not only for his wife and children, but for his slaves also; expressly enjoining that no one of those who

3 The practice of teaching in walking was not peculiar to Aristotle (Ælian. *Var. Hist.* i. 19; Diog. Laert. iii. 11; Brucker, *Hist. Crit. Philosoph.* vol. i. p. 788). Indeed the term περιπατον was applied to "discussion" before the time of Aristotle. Aristophanes uses it humorously in *Ran.* 940, 951, in this sense. The custom appears to have been for the hearers to sit at the lectures of the philosophers. Cleon, in *Thuc.* iii. 38, compares the assembly to "persons sitting spectators of sophists."

Aristotle || Aristotle's Philosophy.

had served him should be sold, but that each should be freed on attaining manhood, according to his deserts.[1]

The fondness of the Greeks for apophthegm has handed down some reputed sayings of the philosopher, such as the following:—Being asked "in what the educated differ from the uneducated," he said, "as much as the living from the dead." Again, to the question, "What grows old soon?" he answered "Gratitude;" "What is hope?" "The dream of one awakened." To one boasting that he was from a great city, "Not this," he said, "should one look to, but who was worthy of a great country." "Some men," he observed, "lived so parsimoniously as if they were to live for ever, whilst others spent, as if they were to die immediately." Being blamed for giving alms to a person of no worth: "It was not to the man," he said, "I gave, but to mankind."[2]

In body, Aristotle, if we may believe the accounts of his person, was deficient in the requisite symmetry. He is described as having slender legs and little eyes. To these defects were added a feeble voice and hesitating utterance.[3] Unlike philosophers in general of that age, he attended to the ornament of his person. His hair was shorn; he wore several rings; and was elegant throughout in his dress.[4] His health was infirm; but he sustained it by habits of temperance, and by that medical skill which he possessed in an eminent degree, so as to protract his life to the 63d year, B.C. 322.

Of his moral qualities, the zeal of philosophical rivalry has transmitted the most discordant accounts. Some have been as extravagant in their praises as others have been in their censures. By some, his patriotism, his affection for his friends, and reverence for his preceptor Plato[5]—his moderation, and modesty, and love of truth—have been held up to admiration. By others, again, no crime has been thought too bad to be imputed to him. He has been stigmatized as a parasite, as gluttonous, effeminate, sordid,[6] ungrateful, impious. Among his faults, too, have been mentioned a sneering cast of countenance, and an impertinent loquacity. In particular, he has been accused of assailing Plato with captious questions, and forcing the old man, when in his 80th year, to retire to the privacy of his garden.[7] Whilst, however, the circumstances in which he lived, exalted as he was by the favour of kings, and by eminence in philosophy, afford a strong presumption that the dark side of the picture has at least been overcharged,[8] we have a more decisive evidence to the truth of the favourable representations of his character in the temper and spirit of his extant writings. Throughout these, there is a candour, and manliness, and love of truth, strikingly discernible; not professedly set forth, but interwoven with the texture of his discussions, and rather betrayed unconsciously than obtruding itself on our notice, and demanding to be recognized. His ethical writings, especially, breathe a pure morality, such as we find in no antecedent philosopher; a morality also avowedly practical, and by which he would have stood self-condemned had his own conduct been at variance with it. (R. D. H.)

ARISTOTLE'S PHILOSOPHY.

Account of the Writings of Aristotle, and reception of his Philosophy.

The preservation of the original copies of the writings of Aristotle is a curious fact in literary history. Whilst the philosopher distributed his other property to his surviving family, he left the more precious bequest of his writings to Theophrastus, his favourite disciple and successor in the Lyceum. By Theophrastus they were bequeathed to Neleus, his scholar, by whom they were conveyed from Greece into Asia Minor, to the city of Scepsis, where he resided. The heirs of Neleus, to whom they next descended, were private individuals, not philosophers by profession, who were only anxious for the safe custody of their literary treasure. The magnificence of kings had then begun to display itself in the collection of libraries, and the works of genius were sought out with an eager and lavish curiosity. It was a taste happy for the cause of literature; to which, perhaps, the example of Alexander's noble fondness for everything connected with intellectual energy had principally led. Aristotle himself, indeed, is said to have been the first to form a library.[9] He was the first, probably, to form one on an extensive scale. The Scepsians, into whose hands his works had now fallen, fearful of the literary rapacity of the kings of Pergamos, resorted to the selfish expedient of secreting the writings under ground. The volumes remained in this concealment until at length their very existence seems to have been forgotten; and they would thus have been lost to the world, but for the accidental discovery of them after the lapse of 130 years. His philosophy had been traditionally propagated; for we hear of Peripatetics at this time. Portions, indeed, of his works must doubtless have continued in circulation among the disciples of the Lyceum, serving in some measure as a record of the principles of the sect. Much may have been preserved from memory: for we have little notion now of the impression made by *viva voce* instruction, when it was the only channel of knowledge to the generality. A Peripatetic philosopher, accordingly, Apellicon of Teos, whom Strabo, however, characterizes as a lover of books rather than a lover of science—*φιλοβιβλος μαλλον η φιλοσοφος*[10]—purchased the recovered volumes, and effectually retrieved them for the world. He employed several copyists in transcribing them, himself superintending the task. Unfortunately, much was irreparably lost, the writings being mouldered with the dampness of the place in which they had so long been deposited. In addition to these damages of time, they were now further impaired by misdirected endeavours to restore the effaced text of the author.

The works of Aristotle, or rather the copies of them thus obtained, were conveyed by Apellicon to Athens, their proper home, though no longer perfect in the text or such exactly as the author had left them. Here this collection of them remained until the spoliation of the city by Sylla. The library of Apellicon was a tempting object of plunder to the Romans, who were now awakened to the value of literature; and Aristotle's works accordingly were carried away to Rome amidst the other rich spoils. At Rome they experienced a better fortune. Tyrannio, a learned Greek, who had been

[1] Diog. Laert. in *Aristot.*.

[2] Diog. Laert. in *Aristot.* The same author mentions an instance of Aristotle's foiling the cynic Diogenes in some premeditated witticism, and gives some expressions by which Aristotle characterized certain philosophers, such as calling Socrates "a shortlived tyranny." The point of these passages, at any rate, escapes the modern reader.

[3] Diog. Laert. *τραυλος την φωνην.*

[4] Diog. Laert.; Ælian. *Var. Hist.* iii. 19.

[5] Ammonius says he dedicated an altar to Plato, inscribing it to him as "a man whom for the bad even to praise would be profane."

[6] Hence the story of his selling the oil which he had used medicinally about his person. (Diog. Laert. in *Aristot.*)

[7] Ælian. *Var. Hist.* iii. 19.

[8] See Aristocles apud Euseb. *Præp. Ev.* xv. 2.

[9] Strabo, xiii. The account given by Strabo has been much canvassed by modern critics.

[10] *Ibid.* xiii. p. 609. Aristocles in Euseb. *Præp. Ev.* xv. 2, speaks of Apellicon as the author of some writings on Aristotle.

a prisoner of war to Lucullus, and was then enjoying the freedom granted to him as a resident at Rome, was the principal instrument in their future publication. Obtaining access to the library of Sylla, he made additional copies of the writings. His labours were followed by Andronicus the Rhodian, who at length edited the collected works of Aristotle, at a distance of nearly 300 years from the time when they were composed.[1]

Meanwhile other sects in philosophy had sprung up, and engaged the attention of the world. The Stoics and the Epicureans, among others, had formed their respective parties. Platonism had obtained permanent establishment at Alexandria. The disciples of Aristotle, on the contrary, had to struggle against the disadvantage of the loss, except, it seems, in some detached portions, of the authoritative records of their master's philosophy. When, however, these records were fully published, they were studied with extraordinary eagerness. A multitude of commentators arose, who exercised their acuteness and ingenuity in explaining the sense of the philosopher. As Aristotle himself by his personal teaching had transcended the fame of his contemporaries, so his philosophy rose up from its long sleep to triumph over every other that had previously engaged the public mind. Platonism, indeed, modified as it was by Ammonius and his successors, continued to be fostered in the early ages of the Christian church, in consequence of the theological cast which it had assumed, and its facility of accommodation to Christian truth. But in the progress of the Church, when Christianity needed to be maintained, not so much by accession from the ranks of paganism, as by controversial ability within its own pale, a more exact method was required. Here, then, the philosophy of Aristotle asserted its value and its pre-eminence.

But it was only a partial Aristotelic philosophy that was at first established. His logical treatises had been studied during the ascendancy of Platonism, for their use in arming the disputant with subtle distinctions, and enabling him accurately to state his peculiar notions in theology. The same occasion still existed for the acuteness of the expert logician, even after the decline of Platonism, in the state of theological controversies. It was still, therefore, chiefly as a logical philosopher, through the several treatises which pass under the name of the *Organon*, that Aristotle was known throughout Christendom. In the west of Europe, indeed, the cloud of ignorance which had covered the lands with thick darkness, limited the attainments even of the learned to a narrow field. The original language of Aristotle's philosophy was gradually almost forgotten; and the generality were restricted to such of his writings as were translated by the few learned men, the luminaries of the long night of the middle ages. The peculiar exigencies of the times, and the taste of the learned themselves, led to the translation in particular of the logical treatises. That on the Categories appears to have been the one principally known among Christians. Nor were these translations always made from the original Greek; but, on the contrary, were in most instances versions of versions. For its knowledge of Greek literature, the west of Europe was indebted to Arabian civilization. The Arabians had, together with their conquests in Spain, imported their knowledge of the Greek philosophy, the seeds of which had been scattered in the East by the learning of the Nestorian Christians. Translations had been made into Arabic, of the Greek authors, and among these, of Aristotle. Jews at the same period were resident in great numbers in Andalusia, the principal seat of Arabic literature. These, by their commercial intercourse with Christians and Mahometans, served as a channel through which the Greek philosophy was carried on from the Spanish Arabians to the Christians of the West. For the purpose of communication, the Arabic versions of Aristotle were translated into Latin, the universal language of early European literature. And thus was the foundation laid of that Scholastic philosophy, through which the dominion of Aristotle was afterwards extended over Europe.

But the occupation of Constantinople by the Latins, in the beginning of the thirteenth century, was the opening of a new era in the literary history of Europe. Greater facilities were afforded by this event for the knowledge of the Greek language. Aristotle began then to be no longer known chiefly as a logician. His physical, metaphysical, and moral treatises were more extensively explored and studied; though at first objection was made to the Physics by the Papal authority. He was thenceforth recognized under the title of *Princeps Philosophorum*. His logic, indeed, maintained its ascendancy in the Schools of Europe; but it was not applied exclusively, as at first, to Theology. It was carried into those new subjects of inquiry which the extended knowledge of his writings had introduced to the learned. The spirit of disputatious subtilty, which, in the beginnings of the Scholastic philosophy, had displayed itself in the quarrels between the Nominalists and Realists, afterwards found employment in the application of logical principles to speculations in physics and metaphysics. At the same time Theology became more and more corrupted by the refinements of systematic exposition; until at length the accumulated mass of error became too evident to be borne, and, among other causes, produced a re-action in the Reformation of the Church.[2]

The abuse of his philosophy, thus manifested, tended greatly to shake the empire which it had held over the minds of men. Had Luther, accordingly, stood alone in the work of reform, Aristotle would perhaps have been altogether banished from the schools of the Reformed. But his roughness of hand was tempered, in this point as in others, by the milder spirit of Melanchthon.

Melanchthon, whilst he had too deep an acquaintance with classical literature not to feel the charm of the writings of Plato, justly vindicated the superiority of Aristotle's philosophy as a discipline of the mind. He therefore assisted in supporting the established dominion of Aristotle in the Schools; whilst he rejected the errors to which it had administered.[3] Afterwards the disputes among Protestants themselves served to perpetuate that dominion: and, from the same cause as before, the subtilties of the Logical and Metaphysical treatises were studied rather than the more practical parts of the philosophy. Thus, even after the labours of Bacon in dispelling the mists which the too elaborate study of Aristotle's system and method by the doctors of the Middle ages, had diffused, his works continued to be read and taught in Protestant Universities. His philosophy, during an empire of centuries, had occupied so many posts in the field of science and literature, that no other, however

[1] Plutarch in *Sylla;* Bayle's *Dict.* art. Tyrannio, note D; Brucker, *Hist. Crit. Philos.* vol. i. p. 799. Andronicus flourished about B.C. 60. The rise of philosophy at Rome was contemporary with him. Cicero in *Tusc. Qu.* i. 1, says, "Philosophia jacuit usque ad nostram ætatem." He speaks, too, in *Fin.* iii. 3, of finding "commentarios quosdam Aristotelios," in the villa of Lucullus. Athenæus, i. p. 3, says the books of Aristotle were purchased of Neleus by Ptolemy Philadelphus, for the library of Alexandria. This may also be true of detached portions of Aristotle's works, or copies of such portions.

Aristotle's Philosophy.

great the improvement, could at once displace it. For thus we find even Bacon himself, in the process of counteracting it, and introducing his "Interpretation of Nature," compelled to use a phraseology founded on the dogmas of the Schools.

It is then of great importance to examine the system of Aristotle in its own authentic sources. Such an examination will convince us, that the philosopher is not to be censured for that depravation of philosophy to which he was made subservient; but rather that, had his teaching been rightly applied, and pursued in the spirit of its author, the Schoolmen could hardly have been led into those airy and unreal speculations which constituted their science of Nature. We are compelled, indeed, to take our estimate of it from such imperfect and often confused relics as time has spared to us out of a far greater mass of his original writings.[1] Fortunately, however, those relics include a great variety of treatises, affording a specimen at least of his mode of philosophizing in every department of science.

State of Philosophy before Aristotle. General Character of his Philosophy.

Aristotle was the first who really separated the different sciences, and constituted them into detached systems, each on its proper principles. Before his time philosophy had existed as a vast undigested scheme of speculative inquiry, fluctuating in its form and character according to the genius and the circumstances of its leading teachers.

Thus the two great fountains of Grecian science,—the Italic school, founded by Pythagoras—the Ionic, by Thales—were both in principle mathematical; though, when we look to their actual results, as they were moulded by their respective masters, the Italic is characterized as the Ethical school, the Ionic as the Physical. Both appear to have been drawn from the same parent-source of Egyptian civilization and knowledge. The mystic combination of mathematical, physical, and moral truth exhibited in the ancient theological philosophy of Egypt, found a kindred spirit in Pythagoras. Hence that solemn religious light shed over his speculations. Mathematical science was the basis of his system. He conceived Numbers to be the primary elements of all things; regarding all other objects of thought as "imitations," or "representations," of Numbers.[2] But the system, as a whole, was a mystic contemplation of the universe, addressed to the moral and devotional feelings of man. Thales was a philosopher of a much more simple cast. Like Pythagoras, he was devoted to mathematical study. He is said to have instructed the Egyptians how to measure the height of their pyramids by means of the shadows; and several of the theorems of the Elements of Euclid are attributed to him. But he did not, like Pythagoras, fall into the error of confounding and blending the objects and facts of the external world with the truths of abstract science. According to him, it was sufficient to shew that water was the element of all things. He sought no deeper cause in any speculation concerning the mode in which this element subsisted. The successors of Pythagoras and Thales variously modified the theories of those great masters. The physical philosophy, however, of Thales, as the more simple and intelligible, and probably also from the greater intercourse of Greece with its Asiatic colonies than with its Italian, especially prevailed in Greece. Thus we find Socrates, who had been the disciple of Archelaus of that school, complaining that the concerns of human life had been abandoned for the subtilties of physics. In the hands of Socrates philosophy resumed its moral complexion. Had it devolved on Xenophon to take the lead as the successor and interpreter of Socrates, things would probably have continued in this course, and ethical science might henceforth have triumphed in the Grecian schools. But the genius of Plato succeeded to the rich patrimony of the Socratic philosophy. And Plato was not one whose ambition could be content with less than the reputation of founding a school, or whose imagination could be tied down to the realities of human life.[3] The mystical theory of Numbers taught by Pythagoras possessed a powerful charm for such a mind as that of Plato. At the same time his power of eloquent discussion found its own field of exertion, in speculaing on those moral truths with which the lessons of Socrates had inspired him. He had also been a hearer of Cratylus,[4] and through him had been instructed in the theory of the "perpetual flux" of nature, the great doctrine of Heraclitus. Plato accordingly applied himself to the combination of these various systems. The theory of Pythagoras was to be retained consistently with the perpetual change of all existing things according to Heraclitus, and with the immutability of nature implied in the Socratic definitions. Definitions could not apply to any perceptible objects, if it were allowed that all such objects were constantly changing. Nor could Numbers sufficiently account for that immense variety of objects which the universe presented. There must therefore, it was concluded, be some existences, independent of the perceptible universe, the fixed objects of definitions; and there must be also an infinity of various archetypes, corresponding to the various classes of external objects. Hence he devised his doctrine of ειδη, or Ideas; a doctrine naturally suggested to an imaginative mind, by the fixedness and universality of the notions signified by language, as contrasted with the perpetual variations of the external world. To these abstract natures, or Ideas, he assigned a real being, as objects of intellectual apprehension; accounting for the existence of sensible things from their "participation" of them. Thus he raised a structure of philosophy on a basis of metaphysics and logic conjointly; or, in other words, Philosophy, in its passage through the school of Plato, had become a transcendental Logic or Dialectic. Dialectic, the science, according to Plato, which contemplates the Ideas themselves, was held forth to the student as the dominant philosophy, the consummation and crown of all sciences.[5]

Such was the state of Philosophy when Aristotle began to teach, and in which he had himself been trained. But it was not a system in which his penetrating mind could rest satisfied. He thought too accurately, not to discover that this cardinal doctrine[6] of Platonism, the doctrine of Ideas, specious as it was, was only a shadowy representation of the objects of philosophy;[7] and that, in order to rest the sciences on a sure basis, a more exact analysis of the principles of human knowledge was required. He accordingly addressed himself to the task of developing a *really intel-*

[2] *Metaph.* i. 6, ii. p. 848, Du Val. *Metaph.* xii. 3. p. 974.

[3] Aristotle (*Rhet.* ii. 23) mentions that Aristippus, alluding to Plato's ambitious manner of expression on some point of philosophy, remarked, αλλα μην δγ' εταιρος ἡμων, ουδεν τοιουτον, "our friend, at any rate (meaning Socrates), has nothing of the kind."

[4] Cratylus found fault with his master Heraclitus for saying that "a man had never been twice on the same river; for no one," he said, "had ever been even once." (*Metaph.* iv. 5.) This was but a natural extension of the doctrine of Heraclitus.

[5] Αρ' ουν δοκει σοι, εφην εγω, ὡσπερ θριγκος τοις μαθημασιν ἡ διαλεκτικη ἡμιν επανω κεισθαι, και ουκετ' αλλο τουτου μαθημα ανωτερω ορθως αν επιτιθεσθαι, αλλ' εχειν ηδη τελος τα των μαθηματων; Εμοιγ' εφη. (Plato, *Republ.* vi. p. 400, ed. Bekker.)

[6] Το δε κεφαλαιον και το κυρος της Πλατωνος αἱρεσεως, ἡ περι των νοητων διαταξις. (Atticus Platonic. apud Euseb. *Præp. Evan.* xv. c. 13.)

[7] Τα γαρ ειδη χαιρετω· τερετισματα γαρ εστι. (Aristot. *Anal. Post.* i. c. 22.)

lectual system of nature, in the stead of that imaginary world of thought and knowledge which the lofty enthusiasm of Plato had created.

He found the several sciences separated from their roots, and vegetating only as stunted branches on a stock unnatural to them. Even Dialectic itself, the master science, was neglected. Its proper nature was mystified and overlooked in that medley of logical and metaphysical truth which had usurped its name; and its relation to the other sciences was misapprehended. In overthrowing the doctrine of Ideas, therefore, he had to make an entire reform of philosophy. And, in fact, he did appear no less as a reformer of the ancient philosophy, than Bacon was of the scholasticism of his day. In each case, idols were enthroned in the niches and shrines of the temple of science; and the hand of a bold reformer was required to cast them down and break them in pieces. If indeed we impartially consider the case, we shall find that Aristotle was animated by the like spirit to that which dictated the method of the Inductive philosophy, and that his reform was directed to the like points. It was his object, as well as Bacon's, to recal men, from their unprofitable flight to universals, to a study of the actual course of nature; and further to direct them into the right path of discovery.

He was the first, accordingly, except in the case of Mathematics, to exhibit a particular science drawn out into its proper system. There was, for instance, a great deal of logical and of moral truth scattered through the writings of Plato: but there was no regular statement of the principles either of logical or moral science, no distinct collection of the proper facts of those sciences, until the treatises of the Organon and the Rhetoric and Ethics of Aristotle appeared. We may easily conceive the arduousness and importance of this service in the cause of philosophy. For any one person to have fully carried into effect such a design, might well be thought impossible. And we shall not wonder, therefore, that in some instances he should have failed, or have merely indicated the proper method to be pursued.

It was not indeed to be expected, that one trained in the dialectical philosophy of Plato should have emerged at once from the prejudices of that system. Aristotle, though professedly opposed to the realism involved in Plato's doctrine of Ideas, yet betrays the power of language over his own speculations, by the importance which he attributes to abstract notions as the foundations of scientific truth. It is a delusion, which the simple attention to the phraseology of one language (and there is no evidence that Aristotle knew any language but his own) is apt to produce. In the analysis of words, we are apt to lose sight of the merely arbitrary connection between them and the objects designated by them, and to suppose that we have penetrated into the nature of the thing, when we have only explored the notions signified by the term. Thus Aristotle, whilst he rejected the Platonic theory of Ideas, still conceived that there were certain immoveable principles, in the knowledge of which true science consisted. He differed at the same time from Plato in his estimate of their nature. Plato regarded the Ideas as archetypes and causes of all sensible and actual existences; whereas Aristotle contemplates them simply as causes or first principles from which all knowledge is derived. He did not allow that these abstractions had in themselves any objective reality or any active power; but he conceived that the speculation about them was an insight into the secrets of Nature.

Philosophy, accordingly, under his hands, stripped of its metaphysical mysticism, assumed a strictly logical aspect. The foundations of science were laid in definitions of those essential natures which constituted the first principles of his system; and from these definitions the truths of the particular sciences were to be deduced.

From this view of the nature of science, it followed that he should employ Induction, rather to determine notions, than to arrive at general principles, such as in modern philosophy are denominated Laws of Nature. In order to discover a first principle, on which a system of science might be raised, it was necessary to state exactly that conception of the mind which belonged exclusively to any particular class of objects. The stating such a conception was, in the phraseology of Aristotle, the assigning of the λογος of the ουσια, or the giving a definition of the object as to its essence. A definition of this kind required an accurate analysis of thought. Every notion common to other objects was to be rejected; and after such rejection, that which remained exclusively appropriate to the object under consideration, was to be assumed as the principle by which its real nature was expressed. The process was not dissimilar to that by which the truths of modern science are elicited; except that the Induction of Aristotle terminates in universal notions; whereas the Induction of Bacon terminates in general facts;—such facts being the utmost that can be obtained from outward observation of objects. It is precisely indeed in this point that the great difference consists between the science of Aristotle and that of Bacon. Aristotle, for example, inquires into the nature of light, and endeavours to define it exactly as it differs from all other natures. This definition is an expression of that principle on which the whole nature of light is conceived to depend. A modern philosopher pursuing the method of Bacon, examines facts concerning it, and, distinguishing those which really belong to it from those which do not, concludes from the remainder some general affirmative respecting it. A modern philosopher often draws a conclusion as to the nature of a thing; as when he infers that light is material, or that the soul is immaterial. But then he does not hold such inferences as principles in the sense of Aristotle; nor does he employ them to interpret the facts of a science. He acquiesces in such conclusions as ultimate principles. He finds, for example, the facts belonging to the falling of bodies on the earth's surface, and to the revolutions of the heavens, coincident in the same general law. He pronounces, therefore, that the principle signified by the term gravity, whatever its nature may be, is the same in both classes of facts. His conclusions at the same time in Natural Philosophy are independent of this assumption; as these would not be affected, though the principle of gravitation were proved to be different in the two cases. If you overthrow, on the other hand, a speculative doctrine of the ancient physics, all the conclusions of the system fall to the ground.

We shall wonder the less at the peculiar complexion of Aristotle's philosophy, when we observe that even modern philosophers have been by no means exempt from the realism which language tends to suggest, and which might almost be termed the original sin of the human understanding.

Such, then, according to Aristotle, was the character of philosophy, so far as it was purely theoretic. It furnished the mind with the means of contemplating nature surely and steadily, amidst the variety of phenomena which external objects presented, by fixing it on abstract universal principles, eternal and unchangeable.

But this was not the only view which he took of philosophy. He did not limit its use to contemplation; though contemplation was its proper function. He regarded it further under two other distinct points of view—as it studied the principles either of effects produced, or those of human actions. Thus, he distributes philosophy in general into three branches: I. Theoretic; II. Efficient; III. Practical. By Theoretic, he denotes 1. Physics, 2. Mathematics, 3. Theology, or the Prime Philosophy, or the science known by the

Aristotle's Philosophy.

modern name of Metaphysics; by Efficient, what we understand by the term Art, as Dialectic or Logic, Rhetoric, Poetics; by Practical, Moral philosophy, as Ethics and Politics. Whilst, then, in order to a purely Theoretic philosophy, he endeavoured to present to the mind the primary elements of thought, following the order and connections of human reason rather than looking to the phenomena of nature, he had a different aim in the two other branches of inquiry, and pursued a different method. In these, his aim was to enable the student to realize some effect, or to attain some good; in Efficient Philosophy, to lay before the mind those principles which impart skill in the arts; in Practical, those by which the goods of life are attained, whether by individuals or by societies. Thus, in both these branches his object, though comparatively limited, was in fact the same as that of Bacon—to increase human power by increasing human knowledge. He has accordingly adopted, in pursuing them, the Inductive method. We find him in these strictly attending to Experience—deducing his speculative principles from facts, and pointing out their application to the purposes of the arts and the business of life. Under the term τεχνη, indeed, which we translate Art, he comprised much more than is understood by Art. Chemistry, for instance, might justly be referred to this branch of philosophy, so far as its principles are applicable to the production of any effect. In fact, it corresponds more nearly with Science, in the acceptation of the word by Bacon, or to what is understood by the term "applied science." For Aristotle himself expressly asserts it to be the result of Experience—observing, that memory of particular events is the foundation of Experience, and that from several experiences Art is produced.[1]

So also, in his Practical philosophy, he directs us not to seek a speculative certainty of principles, but to be satisfied with such as result from the general experience of human life. He further even gives express caution against treating this department in the *a priori* method of his Theoretic philosophy, in remarking that the abstract speculation concerning universal good was unprofitable in that kind of inquiry.[2] Had he viewed Natural Philosophy in its application to the arts, he would surely have introduced the Inductive method there also. Indeed he has done so, wherever particular departments of nature are explored in his writings in order to particular arts. But his works professedly treating of Natural Philosophy belong to a higher speculation, according to his estimate, than those which concern human life. He conceived the things of the material world to be unoriginated and indestructible in their essential nature, and *therefore* the eternal objects of scientific truth,[3] whilst every thing belonging to man was temporary and variable. The former, therefore, were not satisfactorily investigated until they were referred to their primary fixed principles; but of the latter it was sufficient to obtain such knowledge as the contingency of the objects admitted. He perceived, from his accurate and extensive knowledge of human nature, that there was no ground for that realism in Morals which the more uniform aspect of the physical world tended to inculcate. The immense variety of objects to which the appellation of "good" was applied, impressed on his acute mind the conviction that there was no one fixed and invariable principle implied by that term; and that the truths of Moral Philosophy, accordingly, were to be sought simply in an observation of facts, without endeavouring to trace the general facts thus collected to some further abstract principles.

It will illustrate this arrangement of the sciences to look to the Theory of Causation, or the several classes into which Ancient Philosophy distributed the principles of scientific investigation. Now, the classes of such principles assigned by Aristotle are, 1*st*, The Material, or that class which comprehends all those cases in which the inquiry is, *out of* what a given effect has originated. From the analogy which this principle has to the wood or stone, or any actual matter, out of which a work of nature or art is produced, the name "Material" is assigned to the class. But it is not commonly so termed by Aristotle, whose description of it is more precise and just.[4] Unfortunately the term "Material" introduces a misunderstanding on this head. It may be supposed to mean something physically existing, some sensible matter, as wood or stone; whereas, according to Aristotle, it denotes antecedents; that is, principles whose inherence and priority is implied in any existing thing.[5] The Material cause, then, is properly an intellectual principle—one of the elements into which the mind resolves its first rough conception of an object.

The second class of Causes is that to which all inquiries belong which respect the Characteristic nature of a thing. To this Aristotle gives the name of ειδος, form or exemplar.[6] It corresponds with what are termed in modern philosophy "laws of nature." According to Aristotle, and the ancient philosophy in general, it is the abstract essence or being of a thing,—that primary nature of it on which all its properties depend. Bacon, indeed, has retained the name "Form" in his *Organum*, and applied it to denote the generalizations of his philosophy;[7]—a general fact, from its excluding all merely accidental circumstances, being in a manner the proper *form* of the particular facts from which it is inferred, under all the variety which they may exhibit.

The third Class of causes comprehends all inquiries into the Motive or Efficient principles of a thing. It differs from the Material cause—which it resembles so far as it is an investigation of antecedents—in its reference to such antecedents only as are the Means in order to an Effect. We may contemplate a given effect *as such*, and not simply as a mere *event;* and in that case we inquire into the *power* by which it was produced, or the Motive cause. It is to this class that the term Cause[8] is popularly applied, by analogy from the works of human art, in which we discern the connection between means and results. Aristotle, however, did not suppose that we could discover such necessary connection in Nature; signifying by such a cause merely those principles under which all effects, *as such*, might be arranged.

The fourth class in the ancient theory of Causation is what has obtained the appellation of the Final Cause, or, to express it more after the mind of Aristotle, Tendency, or an account of anything from a consideration of its perfect nature or tendency. For example, when we appeal from virtue militant in the world to virtue triumphant in heaven, and explain the present state of moral disorder, by this ultimate view of virtue, or of the end to which it is tending, we argue from a Final Cause in the sense of Aristotle. So, again, when it is argued that the eye was formed for seeing, because its nature is *perfected* in the act of seeing; or, in general, whenever it is inferred that such is the nature of a

1 *Metaph.* i. 1; *Analyt. Post.* ii. last chap.
2 *Mag. Mor.* i. 1; *Eth. Nic.* i. 6.

4 *Nat. Ausc.* ii. c. 3, το ἐξ οὗ γινεται τι ἐνυπαρχοντος, ii. c. 7. *Analyt. Post.* ii. c. 11, p. 170, Du Val. το τινων οντων αναγκη τουτ' ειναι.
5 The premises of a syllogism accordingly are the material cause of the conclusion.
6 Thus he terms it also παραδειγμα, *Nat. Ausc.* ii. 2, Du Val. i. p. 330, the pattern, as it were, of the thing, or its archetype, in the mind.
7 Bacon, *Nov. Org.* ii. 2.
8 The word *cause* is indeed, as has often been pointed out, only a verbal generalization of the different principles to which it is here applied. The Greek word αιτιον, "account," or "reason why," is nearer the truth.

Theoretic Philosophy.

thing, because it is *best* that it should be so. According to modern views, Design is always implied in a Final cause. In Aristotle, it is an intrinsic Tendency in Nature, analogous to the effect of Design.

The division of Philosophy adopted by Aristotle corresponds with this classification of Causes. Physical science, as concerned about objects, of which one rises out of another, or is produced after another, is an investigation of Material Causes. The inquiry is into the law of continuation and succession observed in the natural world,—what the antecedents are in this course,—what the primary principles into which the succession of physical events may be resolved.

The First Philosophy, including Theological, Metaphysical, and Mathematical science, belongs to the Formal Cause. It endeavours to draw forth that secret philosophy by which the mind administers the world of its own ideas; and, by this process to arrive at those primary abstract forms which are the originals, and patterns, as it were, of the various actual forms of things throughout the universe.

Dialectical science, and the Arts in general, are inquiries into Motive Causes, since it is by the Arts that human power is exerted in producing certain effects. The principles of Rhetoric, for instance, are the means by which persuasion is effected. In order to produce any effect, we must observe what acts, what moves, what influences—not simply what precedes or follows in the order of nature; and a study of this kind constitutes what Aristotle calls Efficient philosophy.

The Final cause is the science of human actions, or Practical philosophy. Actions, being the exertions of the inward principles of our moral constitution towards some end, cannot be rightly estimated by viewing them merely as effects, but must be considered in their design or *tendency*. A compassionate action, for example, may, in its actual effect, be productive of evil; but we cannot conclude as to the *nature* of the action from this result. We must further inquire, whether the result was coincident or not with the effect intended, or what it would have been, had the action been perfect as the exertion of the principle; that is, we must inquire into its Final cause.[1]

But though this is the appropriate classification of the principles of the several sciences, it does not follow that any particular science is restricted to one particular mode of speculation.[2] The several kinds of Causes are all employed as modes of analysis under the same head of philosophy.[3] As all philosophy, indeed, ultimately refers to the principles of the human mind, so far every science is a speculation of the formal cause. In Aristotle's system of Physics, the speculation of the Final Cause occupies the *principal* place, instead of being employed, as in modern philosophy, in subordination to the inquiry into the Material and the other Causes.

Theoretic Philosophy.

Physics, Mathematics, Metaphysics.

In proceeding to examine the several sciences included in this threefold division of Philosophy, and contained in the extant writings of Aristotle, those which he has classed under the head of Theoretic philosophy, as being the only *proper sciences* in his view, naturally come first to be considered. These, then, are Physics, Metaphysics (or Theology), and Mathematics.

There is the less occasion for considering these sciences distinctly, as Aristotle has not strictly maintained their separation, but has often blended their different principles in the same discussion. In this department of philosophy he receded less from the dialectical system of Plato, and felt the influence of that system attracting him into its vortex. As Plato, by drawing off the attention of the philosophical inquirer from nature itself to the Ideas of his intellectual world, was led to confound all the sciences in one philosophical reverie; so Aristotle, in the Theoretic branch of his philosophy, looking to the primary principles of the sciences as they exist in the human mind, rather than to the phenomena of each, overlooked their real differences in his mode of treating them. The ground of this promiscuous discussion is to be found in that classification which he adopts of the objects of these three sciences.[4] They are all, in his view, conversant about *τα οντα*, or things that ARE; but differing in the mode in which they abstract the notion of BEING from existing things. The science which considers Being in union with matter, or as it is evidenced under those variations which the material world presents, is Physics. That which considers Being as it is conceived apart from the variations of the material world, though still not separate from matter, is Mathematics. Lastly, that to which the name of Metaphysics has been given by his commentators, but to which Aristotle himself assigns the name of Theology, or the First Philosophy, is the science which considers Being apart both from the variations of the material world, and from matter. It appears, therefore, that the object of his inquiry in each of these three sciences is ultimately the same. He is engaged in all, in investigating those universal principles under which existing things are arranged by the mind. For this is the meaning of the term Being in his Philosophy. It stands for any of those conceptions by which the various natures or properties of things as they exist, are represented in the mind. These sciences, accordingly, not differing fundamentally in his view, he was naturally led to combine them in one general speculation.

Hence the abortive and futile character of his Physical philosophy. Instead of looking to the phenomena of the material world, he was employed in arguing from metaphysical and mathematical data, from mere abstract notions, to the realities of external nature. Thus, instead of being an investigation of the laws of nature, his system was a vain fabric of speculative reasoning from assumed principles. Whilst he thought that he was discussing and stating truths of physical science, he was only analyzing certain notions of the mind, and accurately defining them. No other method, indeed, is open to the philosopher, who would penetrate the veil of the actual phenomena, and establish a certainty of science beyond what is conceded to man, but that of abstract Definitions. These being once laid down, the truths of science follow by necessary connection; for they are then the mere development of general assertions into the particulars implied in them, or connected with them. But, the cer-

[1] The same principle applies to the arts also, so far as the skill in any art is exerted in action. We then judge of the art so exemplified by its tendency to produce the *proper* effect; of the wisdom, for instance, of the politician by the adaptation of his counsels to the welfare of his country—or of the military skill of the general by his plans—not simply by their result; which may accidentally be untoward.

[2] *Nat. Ausc.* ii. 7, *επει δε αιτιαι τεσσαρες, περι πασων τȣ φυσικȣ ειδεναι· και εις πασας αναγων το δια τι, αποδωσει, φυσικως, την ὑλην, το ειδος, τȣ κινησαν, το ȣ̔ ἑνεκα. ερχεται δε τα τρια εις το ἑν πολλακις· κ. τ. λ.*

[3] Thus an action may be analyzed into the affection exerted in it (the material or physical cause), the choice of the agent (the motive cause), the end to which it tends (the final cause), the definition of the virtue to which it belongs (the formal cause); and yet the science of the action is fundamentally an inquiry into the final cause.

[4] *Metaph.* vi. 1, and xiii. chap. 1, 3, and 4. See also *Nat. Ausc.* ii. c. 2.

Theoretic Philosophy.

tainty and necessity of such conclusions are nothing more than consistency with the original assumptions. It would be absurd to suppose them otherwise, because this would be to contradict what has been already asserted. Aristotle indeed expressly says, that truth of fact and truth of science are not mutually implied in each other. "Impossible and possible, and falsehood and truth," he observes, "are either hypothetical—as it is impossible for a triangle to have two right angles, if this is so, and the diameter of a square is commensurate with its side, if this is so,—or absolute. But absolute falsehood and absolute impossibility are not the same; since, for one not standing to say he is standing, is false, but not impossible; and for a harper not singing to say he is singing, is false but not impossible; but to stand and sit at once, or for the diameter to be commensurate, is not only false, but impossible."[1] Still he sought to unite both kinds of truth in his physical speculations; and in the vain attempt, lost sight of the absolute truth contained in the facts presented to his observation.

The first portion of his Physics, contained in a treatise in eight books, entitled *Natural Auscultations*, is devoted to inquiries into principles; with a view to ascertain those fundamental conceptions from which all conclusions concerning physical objects were, in the *a priori* spirit of the whole inquiry, to be deduced. Agreeably to this order, he sets out with discussing the question, whether these principles should be ultimately referred to one or more than one, and laying down his own doctrine of three principles, under the established denominations of, 1. Matter, 2. Form, 3. Privation. These are the principles which, as employed by his disciples of the middle ages, have occasioned much undue censure of the philosopher. His system, indeed, is sufficiently condemned in its hypothetical character, but is guiltless of the absurdity which modern refinements have cast upon it. These three principles rightly viewed are general conceptions of the mind, as it endeavours to class the various objects of the sensible universe, and to refer the succession of events without itself to some ultimate unchanging views within itself. It has been already stated what is meant by a material cause, the ἐξ οὗ or ὕλη of Aristotle. These principles, then, are only different modifications of this cause. They are antecedents, or notions at which the mind ultimately arrives, in an analysis of its complex notions of natural objects; and therefore antecedents, because they must be presupposed in every contemplation of the natural world. The terms by which they are denoted are merely analogical. Aristotle, proceeding on a principle of the Pythagorean school,—indeed the common doctrine of philosophers before him,[2]—argues that, as contraries cannot generate contraries, there must be at least two opposite classes of principles. In the changes observed in the course of the world, one object is succeeded by another; something has passed away, something is produced. Two fundamental notions, therefore, are involved in every contemplation of nature. These accordingly are expressed by the terms *Form* and *Privation;* imperfectly characterizing these subtile abstractions, though justly, so far as the relation denoted corresponds with that between the present form of any material object and the previous forms superseded by it. For example, a statue is a form constituted in the stead of the rough block, and of that infinite multiplicity of figures of which the marble in its unmoulded state was susceptible. Of these it is, as it were, "deprived," in the act of producing the statue. The analogy, however, is apt to induce us to suppose that something positive is implied by the terms *Form* and *Privation* in the language of Aristotle. Hence the ridicule with which the statement of Privation as a physical principle has been received. But if rightly understood, it holds a just and important place in the physical philosophy of Aristotle. And to see the proper nature of it, it should be observed, that it applies no less to immaterial objects than to material.[3] For instance, if we look at man physically, we observe that he is capable of moral improvement. Supposing him, then, civilized and improved beyond his ordinary state, we perceive in such a case a transition from a state of barbarism to a state of culture. The state of culture, then, is the Form of which Aristotle speaks; the state of barbarism, which may be in infinite varieties of Form, the Privation. Or, a person becomes healthy from being diseased: health is the Form superinduced; the Privation is of every species of disease. But besides those principles which are excluded in the physical constitution of anything, and so referred to the head of Privation,—and those again in which the peculiar constitution of the thing is found to consist, and which are therefore referred to the head of Form,—there are evidently other principles which remain the same in all variations of Form. The internal nature of physical objects subsists under all external changes. The notion, therefore, by which that nature is represented to the mind, must be respected, in accounting for the physical constitution of a thing; as being an antecedent out of which it proceeded. To this notion, or class of principles, by which the one common nature of all physical objects is denoted, Aristotle applies the name of ὕλη, or matter: this notion being analogous to the stuff or substance of which different works of human art are constructed, as marble or brass is the material of which different statues are made[4].

Now, beyond *these* abstractions, it is impossible to proceed in the speculation on physical existence. They comprise, in fact, the whole of modern investigations in physics. Modern physical science has followed an order exactly the reverse of that of Aristotle. It has ended where he began. But it has had *these* several principles in view. The *abscissio infiniti*, prosecuted in the inductive method of philosophy, is analogous to the "privation" of the ancient system. It is a continued process of separating from any subject under examination, those natures or principles which do not constitute the proper nature of the subject, and thus gradually narrowing the inquiry more and more, until we have at last obtained some ultimate fact, expressing the proper nature of the thing. This ultimate fact, accordingly, Bacon terms the "form" of the thing, adopting the received language, whilst varying its sense to denote the ~~law or~~ principle by which it exists. It is the ~~result which~~ remains to be affirmed, after rejecting and excluding other principles; or, in other words, after the subject has been "deprived" of all those "forms" in which its proper nature does not consist. Again, Bacon directs that a collection be made of all those "*instantiæ,*" instances to which the form in question seems to belong. These instances, so far as they agree in this respect, correspond with the Material principle of Aristotle. They exhibit that common nature, in some one form of which the particular nature sought must be found.

It is not meant here that Aristotle conceived of these principles according to this view of them. The design of his inquiry is, by an analysis of Nature, to obtain those fundamental notions to which all the various notions involved in the speculation of Nature might be referred. For he explains things that have their being by Nature, to be such as have *in themselves* a principle of motion and rest,

[4] *Nat. Ausc.* i. 8, Ἡ δε ὑποκειμενη φυσις, επιστητη κατα αναλογιαν· ὡς γαρ προς ανδριαντα χαλκος, η προς κλινην ξυλον, η προς το αλλο τι των εχοντων μορφην, ἡ ὑλη και το αμορφον εχει, πριν λαβειν την μορφην· ὅτως αὕτη προς ουσιαν εχει, και το τοδε τι, και το ον.

Theoretic Philosophy.

as contrasted with works of art, the principle of which is in the artist.[1] Aristotle's object, accordingly, is to examine this inherent principle of motion and rest, which is the nature of a thing, and to shew how it operates in producing the various forms observed in the world around us. His error was not unlike that of one who should profess to give an account of visible objects solely from what they *appear* to the eye, and who should accordingly describe such objects as flat surfaces, variously shaded and coloured. From this view of the object of natural philosophy, he was led to account for the processes of generation and corruption, and the changes which occur in bodies by alteration, increase and decrease, local motion, mixture. Consequently, he states the great principles of Matter, Form, and Privation, as generalizations of those latent processes by which physical effects are produced, rather than as principles by which the investigation of nature must be guided. Hence the perverse application of his physical philosophy in the middle ages to work transmutations in nature. The labours of the alchemists were nothing else but a practical realism founded on the speculative principles of the philosopher.[2]

The discovery of the principle to which the denomination of Form is assigned, is, in Aristotle's system, as in Bacon's, the ultimate point of physical inquiry. The investigation of the principles of Matter and Privation is in order to the discovery of the Form; which is thus the τελος, the end, or completion of the process of nature. The principle of self motion, or instinctive tendency, which, according to Aristotle, is the proper object of physics, is then traced to its effect on the thing produced, and we have obtained the *ουσια*[3] or proper being of the thing.

From this view of the principle of Form, as the result of a self-working power in Nature, results the peculiar character of Aristotle's physical philosophy. He thought it evident, from such facts as the provident care shewn by spiders, ants, and other animals, and the service of the leaves of plants in protecting the fruit, that nature intrinsically possessed this power of working certain ends.[4] The form, then, of every physical object being the attainment of such an end, and the form also constituting the being or nature of the object, occasion was furnished for speculating *a priori* from the supposed perfection, or view of what was best, in anything, to the form or law in which its nature consisted. This mode of speculation was embodied in those maxims of ancient philosophy, that "nature does nothing in vain;" that "nature always works the best that the case admits;" that "nothing by nature is imperfect."[5] The consequence was, that the very point to be ultimately investigated was assumed at the outset of the inquiry, and the conclusions accordingly were only hypothetically and not absolutely true. And thus it is that Aristotle expressly admits the necessity which belongs to physical truths to be hypothetical—dependent, that is, on the assumption of the end pursued by nature, in like manner as the conclusions in mathematics are dependent on the assumption of definitions.[6]

It is curious to observe the traces of such a doctrine in different systems of philosophy, as they appear under different modifications. In some of the older theories, we find indications of it in the hypothesis of two opposing principles, as love and enmity, by which it was proposed to solve those appearances in nature which were adverse to the notion of the tendency of Nature to the best. In the systems of Parmenides and Hesiod, love and desire—in that of Anaxagoras, intellect—were the expressions of this tendency. In the philosophy of Plato, it was evidenced in the rejection of the material world from the class of permanent and real existences; this doctrine being a ready transition from the notion which attributed the physical constitution of things to their dependence on some primary ideal principles. Modern deists have argued in the same way, when they have rejected a Revelation because the things contained in it did not correspond with what they had determined to be "best" in nature.[7] In Aristotle, on the contrary, it was shewn in the theory of the Eternity of the Universe. For if Nature is an active principle, ever tending to realize in act the perfect form of everything, the existence of the universe at all times is necessary as a condition in order to this end.

The great doctrine of the ancient physics, that "nothing could be produced out of nothing,"[8] required no distinct consideration according to the theory of Aristotle. Inquiring into nature simply as a principle of motion, he was only called upon to shew how those changes which took place in the material world might be accounted for. It was no part of his philosophy to demonstrate that any particular element, or combination of elements, was employed in the laboratory of nature for effecting the various productions and transmutations. All he assumes is, that some material or other is employed in every instance, to effect that perfect constitution of it in which its "form" consists. An object, indeed, is not a physical object, unless it is conceived in conjunction with "matter." If only it has "matter,"—that is, a nature capable of affecting the external senses,—what particular kind of matter it may have, is irrelevant to his inquiry.[9] For example, whether water or air must pre-exist in the production of the other of these two elements, is not the point with which he is concerned. It is enough that there is in every physical effect a principle of motion operating. It follows, from the existence of such a principle, that there must be also "matter;" otherwise the *material* effect—the effect cognizable by the senses—would not have been produced.

The analogous inquiry in his system is, what principles are *prior* in the order of transition, so that from their presence or absence the constitution of any particular body results? What are those, in any instance, which never pass into each other, and of which a physical object cannot be deprived without its destruction; and which may therefore be regarded as elementary principles.

Hence his detailed investigation of Motion, in the technical sense in which the term is employed in his philosophy. In his system, changes of place or quantity or quality, generation and corruption, the action and passion of bodies, their mixture, are all instances of Motion. Hence also his discussion in his physics of questions which, in modern philosophy, are more properly regarded as the province of the metaphysician; as the nature of infinity, of time, and place, &c.: all which subjects, however, belong to his inquiry,

Theoretic Philosophy.

inasmuch as they are implied in the various processes of Motion.

A speculative difficulty, however, occurred in the prosecution of this physical theory, like that which perplexed the material philosophers in respect to the pre-existence of matter. He had to account for the production by Motion of "a Form" not previously existing.[1] This he explained by the subtile distinction between potential and actual being. This, in fact, is his analysis of Motion; Motion being the exertion in act of that intrinsic efficacy which is in a thing to produce a particular Form. He speaks of this power in Nature of working ends, as analogous to the skill of a physician[2] working his own cure. Nature, which is thus in his view as a kind of life[3] to all existing things, realizes in itself those principles, which are inherent in its constitution, before latent but now developed, when an actual effect takes place. Nothing, accordingly, is produced, in his system, which was not, though in another mode, before in existence. What already existed potentially is produced into actuality and manifested to our perception in some physical object.[4] To describe it in terms of modern philosophy, we should say it was a transition from metaphysical existence to physical; from the subjective to the objective; from an object of the mind only cognizable by the internal principles of our constitution, to an object of the external senses;—the mind perceiving the principle of motion *as a principle,*—the senses giving us the impression of the principle *moving* or operating on matter.

This doctrine of potential being, transmitted by the speculations of the schools, and perverted to realism, has given occasion to represent a coincidence on this point in the system of Aristotle with the ideal theory of Plato, the very part of Plato's philosophy which Aristotle most directly opposed. But it should be observed, that the forms of which Aristotle speaks are not, like the ideas of Plato, separate existences, constituent of physical objects. They are the philosophy of nature considered as an instinctive principle of motion—general principles under which the mind classes the effects of physical power, analogously to its own operations when it proceeds to realize in some outward act any idea which it has conceived.

Leaving, then, the question as to the element or material itself, of which physical objects are composed, untouched, Aristotle examines what principles reject and exclude one another in the various changes of the material world. For these are the causes of the transitions of one nature into another, and of generation and corruption: the presence of one involving the privation of all those forms of matter dependent on the presence of the other. What these mutually excluding principles are, he decides by a reference to the sense of touch; that being the proper evidence to us of the existence of body. Sight, indeed, may give us the first notices of the *existence* of a material thing; but it does not inform us of the *material* nature of the thing. This we infer from the resistance to the sense of touch. Accordingly, Aristotle explains what is sensible to be what is tangible.[5] The contrarieties then ascertained by touch, and which account therefore for all the different forms of matter, are hot and cold, dry and moist; the first two as active principles, the last two as passive. The touch, indeed, informs us of other contrarieties, but they are all reducible to these four heads, with the exception of light and heavy. The last are excluded from the class of physical principles. For though, in common with other ancient philosophers, he held them to be positive and absolute natures, he found, that they could not act on each other, and therefore could not effect any physical change. As hot and cold cannot co-exist, nor can moist and dry, these four principles admit only of four combinations: and the effect of each combination is a different element. The combination of hot and dry, is fire; of hot and moist, air; of cold and dry, earth; of cold and moist, water. Any one of these element may pass into another[6] by the privation of one of the combined principles. In such an event, the contrary principle, which had been only excluded by the presence of its contrary, combines with the remaining one. For example, water is transformed into air, by the privation of cold, and the consequent combination of hot with the moist which remains. Or both principles combined may be superseded by the two opposites, as when fire and water may be changed into each other. Thus there is a subordination of principles wherever the principle of motion is exerted in act. First, there must be matter, that is, a principle susceptible of the contrarieties; then the contrarieties; and last of all, the material elements themselves.[7] When the change effected involves an entire change of the material from which it proceeds, the process is that of generation and corruption. But when the change is simply in the affections of some existing body, as in the instance of a person from being unmusical becoming musical, or of the food of an animal being converted into its substance, the process is that of alteration.[8]

Thus does Aristotle account for all the changes which take place in the world immediately about us. Whether we observe things generated, or altered in their sensible qualities, or varied in bulk, or place (and to one or another of these every physical effect may be referred), the changes observed may be traced to the operation of a principle which is either one of these four already mentioned, or some modification of them. For all the intermediate principles between two contrarieties, or the degrees of them, are to be regarded as contrary, and capable therefore of effecting physical changes in the same manner as the extremes.

But the changes which occur immediately in the world around us, constituted, in the view of the ancient philosopher, a very inferior part of the objects of physical science. The luminaries of the superior celestial world were regarded by Aristotle as more excellent than man, and the study of their laws as a higher employment of the intellect than the philosophy of human life.[9] Besides, however, the intrinsic excellence of this branch of physics, it demanded his attention from its necessary connection with the development of his theory of Motion. Now, all other physical changes imply local change. Local change may therefore be inferred to be prior to every other.[10] Further, to keep up the constant succession of generation and corruption which is carried on in the world, and the passing of one nature into another, there must be some principle ever in *actual* being. But, no other than the revolution of the heavenly bodies continuing incessantly, this alone exhibits a principle of local motion adequate to the effect. Aristotle, accordingly, was led to speculate on the motions of the heavens, in order to trace up the propagation of Motion in this lower world, through its successive impulses, to the First Mover. This being discovered, his philosophy of Nature is completed: since Nature is then fully explored according to his analysis, as the principle of motion and rest.

His whole astronomy is deduced from the notions of lightness and heaviness, as intrinsic and absolute properties of

Theoretic Philosophy.

bodies. He considers lightness the same as positive tendency upwards, and heaviness as positive tendency downwards. But this view implied that there were certain fixed points, the extremes to which these qualities of bodies tended, and in which bodies naturally rested as they possessed either lightness or heaviness. Each of the material elements, accordingly, had its proper place in the universe, corresponding to the degree of lightness or heavinesss which he conceived them to possess, both absolutely in themselves, and relatively to each other. Fire he placed in the extreme point upwards, earth in the lowest; air next to fire, and water next to earth. Each of these elements, therefore, he argued, as naturally tending either upwards or downwards, moved in a straight line, and could not consequently move *naturally* in a circle. Hence the earth must be at rest, and therefore be the centre of the universe. For if it revolved round the sun, as the Pythagoreans thought, it would be moving unnaturally, and therefore could not move eternally. Hence, also, no revolving body could consist of any of the four material elements. It must be some other material, some other element, to which circular motion was as natural as rectilineal motion is to earth or fire.

On the ground of such speculative notions Aristotle proceeded in constructing his system of the universe; in opposition to the more enlightened conclusions of the Pythagorean, and the records of Egyptian and Babylonian[1] observations on the heavens. In some instances, indeed, his view was more correct. He admits the spherical[2] form of the earth, from the evidence of lunar eclipses, in which he had remarked that it always exhibits a curved outline; and infers its magnitude to be not very great,[3] from the variation of horizon consequent on a little variation of our position on its surface. But, in acknowledging these facts he was influenced by their accordance with his speculations *a priori*, as he rejected or misinterpreted other facts from their repugnance to these speculations. For the spherical form of the earth resulted from his theory of heaviness. It was the effect of the tendency of all the particles of the earth to the lowest point; this lowest point being a centre of the two opposite hemispheres of the heavens. For, that the whole heavens were spherical, he supposed a necessary consequence of the perfection belonging to them, a solid being the perfect mathematical dimension. The tendency, consequently, of all the particles of the earth to the lowest point, was a tendency towards a middle; or this lowest point would be a centre round which the earth would adjust itself in a spherical mass.

The reason assigned by Aristotle for the revolutions of the heavens, as appears, then, is precisely opposite to that of modern philosophy. He conceived revolution to be performed, not in consequence of a tendency to the centre, but of the absence of any such tendency in the revolving body. Revolution and gravity are, according to him, contradictory terms. The motions of the several heavenly bodies result from their being carried round by spheres, which consist of this revolving element. That they do not revolve in themselves he considers to be evident from the fact that the moon always presents the same side towards us. They are incapable indeed of motion in themselves, he argues, in being spherical, nature seeming purposely to have denied them all power of motion in giving them the form least apt for motion. They revolve, therefore, from being bound in revolving spheres, the first in order of which is that in which the fixed stars are placed, and then the several planets (five in number), the sun, and next to the earth the moon;[4] and to account for the apparent irregularities in the motions of the heavenly bodies, he supposes, following the theory of Eudoxus,[5] that there were as many additional spheres employed in the revolutions of each body as it appeared to have different motions.

The oblique motion of the sun, viewed in connection with the successive renewals and decays of nature, as he approaches or recedes from the earth, suggested the most ready link for connecting the phenomena of the earth with those of the heavens. It is, accordingly, to the revolution of the sphere of the sun, that Aristotle ascribes the continuation of generation and corruption in unbroken series, and the consequent perpetuity of being in the world around us. It might be supposed that generation and corruption would be carried on at equal intervals. But the unequal temperament of material things prevents such a uniformity; and occasions that variety of duration, which we observe in different things within the sphere of the moon, the sublunary world, or the limits of Nature properly so called.[6]

Still, however, it remained to be explained what it was that imparted to the sphere of the sun, as well as to the several other spheres, their principle of motion. To every thing that is itself moved there must be a mover: and the successive motions, therefore, as communicated from sphere to sphere, must be traced up to some first principle, itself unmoved, in which they originate.

Here, then, we discern the close connection of Aristotle's Physics with his Metaphysics; and at the same time the ground of his applying to the latter science the designation of Theology. The several spheres of the heavens, differing in element from the bodies of this lower world, and pursuing their unceasing and immortal revolutions, presented a distinct class of ουσιαι, beings, or substances, to the speculation of the philosopher. To ascertain that in which they moved and had their being, was an inquiry, with regard to them, analogous to his investigation of the principle of Motion in the natural world. This principle of motion to these celestial substances would be Being itself, or the very vital Energy in which they had their being.[7] At the same time, in exploring this primary Being, he would be tracing those general principles by which the mind held together the various objects of physical contemplation to one primary law or master-principle, in which, as in a single theorem, all the truths of philosophy should be comprized.[8]

This intimate connection of Theology with Metaphysics, in the Ancient Philosophy, was a natural consequence of the separation which heathenism established between Theology and Religion. In the civilized states of antiquity, Religion was pursued only as a matter of policy, and not as a rule of

[1] *Metaph.* i. 1. Herodot. *Euterp.* 109.

[2] He speaks of it in *Meteor.* ii. c. 5, p. 562, as shaped like a tympanum.

[3] Mathematicians, he says, had computed its circumference to be 400,000 stades, or about 40,000 miles.

[4] The Pythagoreans connected with this notion the beautiful fancy of the music of the spheres. Aristotle expresses his admiration of the thought, but denies its possibility. The stars move with the spheres, he says, like the parts of a ship with the ship, and therefore can make no sound. (*De Cœlo*, ii. 9.)

[5] *Metaph.* xiv. c. 8. Eudoxus assigned fifty-five spheres on the whole; or, deducting those added to the sun and moon, forty-seven. Aristotle only states this as what may reasonably be thought; leaving, he says, the assertion of its necessity to others more positive, *ισχυροτεροις*, than himself, p. 1003, Du Val. Eudoxus of Cnidus went into Egypt about 368 B.C. and introduced the regular astronomy from Egypt into Greece. Aristotle gives him the high praise of recommending his theory of Pleasure as the Chief Good, by the distinguished morality of his life. (*Eth. Nic.* x. 2.)

[6] *De Gen. et Cor.* ii. c. 10.

[8] *Metaph.* iii. 2, *ἡ μεν γαρ αρχικωτατη, και ἡγεμονικωτατη, και ἡ ὡσπερ δουλας ουδ᾽ ἀντειπειν τας αλλας επιστημας δικαιον, ἡ του τελους και τἀγαθου τοιαυτη.*

Theoretic Philosophy.

Theoretic Philosophy.

life to the individual. Whatever was the established creed of the state, it was the recognized duty of the good citizen to support as established.[1] Not involving any question of truth or falsehood in the particular creed adopted, it readily admitted of any additions of superstition not repugnant to the laws and manners of the state; but imperiously rejected all questioning of the fundamental assumption of the importance of that which was established.[2] It may be said to have been the great principle of their religion, that it should be made no question of truth and falsehood. The religious instincts of the human heart were under such a system at once gratified and diverted from their proper end. Their strength was spent in the vain amusement of festal ceremonies, and their purity corrupted by demoralizing orgies. In this state of things, the better and wiser part of men were driven into a metaphysical religion. They could not acquiesce in the views of the Deity presented by the popular superstitions. Yet the subject could not but recur to them in the reasonings of their hearts, as soliciting earnest inquiry. They searched for God, accordingly, not seeking what to *do*, but what to *know*. Whatever the truth concerning Him might be, it was not to be expressed in the uplifting of pure hearts and hands to Him. Though the whole world might be found his temple, He was not to be worshipped as the Holiness of their shrines. Though the heavens were telling of his glory, and the stars were singing together for joy at his presence, yet no praise was to ascend to Him, the Lord of heaven and earth, in the perfumes of their altars, or the poetry of their hymns. Thus devotion, being banished from the heart, sought a refuge for itself in the wilderness of a speculative theological philosophy. Hence Socrates and Plato, and Aristotle and Cicero, and other illuminated sages of heathenism, continued, without hypocrisy, professors of the established religion, whilst they aspired after a purer knowledge of God in the thoughtful abstractions of their own intellect.

Looking, then, at the admirable order of the heavenly bodies, the philosopher saw, in their unvarying regularity, the immutable and eternal nature of the great Principle on which their motions depended. He did not, it seems, attribute to them a proper divinity in themselves; for he refers their perpetuity of motion to the ultimate principle or First Mover, the Deity of his system. But he speaks as if they possessed a divine nature.[3] He also says that we must think of them as partaking of life and action. He must be supposed, however, by such expressions, to be giving only an analogical description of the perfection in which they display the efficacy of the First Great Principle. Contrasted with the unstable things of the earth, they evidence the Principle of Motion perpetually operating without interruption; whereas the successions of generations and corruptions about the earth only approximate to the perpetuity of the heavenly motions. We ought indeed to interpret in the same manner his ascription of power to Nature as a Principle of Motion. It seems as if he was excluding the agency of Deity. But in truth he is only tracing the mode of the operation of the First Principle. For he thinks that all things attain the good of their nature, so far as they have something *divine* actuating them. It is this divinity in them which is the primary source of all perceptions of pleasure.[4] Further, it is the indistinct apprehension of the same that he supposes to be the motive of exertion in all things that are capable of action, though they may be unconscious of its being so.[5] Hence it has been maintained, that the doctrine of Aristotle differed but little from the pantheism of the modern infidel.[6] The operations of Nature, then, as well as the revolving spheres of the heavens, are divine, inasmuch as they illustrate more or less perfectly the animating principle of all Motion,—the operation of Deity itself. At the same time, there is no notion of Deity inculcated under the idea of the Creator and Governor of the Universe. It is simply as the Life of the Universe—the Intellect—the Energy—as what gives excellence, and perfection, and joy to the whole system—that his philosophy sets forth the notion of Deity. It is, in short, pure Being, abstracted from all matter, and therefore only negatively defined as without parts or magnitude, impassible, invariable, eternal. But whilst his system included no providence,[7] it has the merit of excluding the operation of chance and accident. These, he observes, are not capable of being causes of any thing; they are merely descriptions of what takes place contrary to some presupposed design, or some tendency in Nature.[8]

In his Metaphysics, properly so called, he considers this First Principle strictly in a metaphysical point of view. His professed object here is, to inquire into "Being so far forth as it is Being, and the general properties belonging to it as such."[9] Having traced the changes which occur about the earth to a fixed principle, he had presented one unchangeable point of view in which the human mind might contemplate the vast and restless variety of physical objects. It remained for him, then, to examine this principle in itself, in order to attain a sure and perfect science, the highest and first Philosophy, in the knowledge of the fixed and immutable, and necessary.

---

[1] See Xenophon's *Memorab.* iv. c. 4. The great rule of piety inculcated by Socrates is, Νομῳ πολεως. See also Polyb. vi. 56.

[2] Even Aristotle says that there are some who are not to be argued with; and mentioning such as require punishment rather than argument, he instances in those who question "whether one ought to honour the gods, or love parents," *Top.* i. See also *Eudem.* i. c. 3.

[3] *Metaph.* xiv. 8. p. 1003, "It has been handed down by the primitive and ancient, left to those after them in the figure of fable, both that these are Gods, and that the Divinity encompasses universal nature. But all else has been fabulously associated for influence with the multitude, and for its use in respect to the laws and expediency. For they say that these are of human form, and like some of the other living beings; and other things, they say, consequent on, and similar to those mentioned. From which accounts should one separate and take that only which was first, that they conceived the first Beings to be Gods, he might consider it to have been divinely said; and that, as probably each art and philosophy has been often discovered to the utmost and again lost, so also that these their opinions, like relics, have survived up to the present time. Now our hereditary opinion, and that derived from the first men, so far only is manifest to us."

[4] *Eth. Nic.* vii. c. 13, παντα γαρ φυσει εχει τι θειον, κ. τ. λ.

In *De Anim.* i. 3, he substitutes "the Deity," where, according to his usual mode of speaking, he would say "nature," καιτοι γ᾽ εχρην τον θεον, κ. τ. λ. p. 625, Du Val.

[6] See Bayle's *Dict.*, article Aristotle.

[7] There is a passage in his *Ethic. Nicom.* x. 8, in which he alludes to the supposition of a divine superintendence, επιμελεια; but he there evidently makes the appeal rhetorically, to recommend that cultivation of the intellect in which he places man's highest happiness. A further evidence of this is, his speaking of *gods* in the plural in that passage. At any rate, the superintendence here spoken of is distinct from what we mean by providence, as he does not suppose it extended over the bad as well as the good. In his *Magna Moralia*, ii. c. 8 (Du Val, vol. ii. p. 185), he argues that the superintendence and benevolence of the Deity cannot be supposed the same as good fortune, ευτυχια, because it is not reasonable that the Deity should superintend, επιμελεισθαι, over the bad; and that we observe the bad sometimes fortunate.

[8] This view of Chance agrees with the remark in Thucydides, that "we are accustomed to charge Fortune with whatever happens παρα λογον, out of, or beside, the course of reason," book i. chap. 140. Aristotle has expressed the same in his *Rhetoric*, i. c. 5, εστι δε και των παρα λογον αγαθων αιτια τυχη.

[9] *Nat. Ausc.* ii. 6, 7, 8; *Metaph.* xiii. 8.

Theoretic Philosophy.

This employment of the term "Being" may give the appearance of the investigation being concerned with positive objective realities, independent of the human mind for their existence. But though his mode of expression, and perhaps his example in some parts of his Metaphysics, may have afforded occasion to the ontology of the schools, he cannot justly be charged with the realism and absurdity of that system. These may be traced chiefly to a circumstance already adverted to—the introduction of Aristotle's philosophy into the Western Church by the medium of Latin translation. The term *ουσια*, by which he denotes existence in the abstract, as distinct from any object of which it is affirmed, having been rendered in Latin by *substantia*, it came to be supposed that the natures or principles represented by the term had a real subsistence. Thus the doctrine of Aristotle respecting Being was understood in a sense precisely the reverse of that which the philosopher himself intended. The analogy on which the application of the term *substantia* to metaphysical subjects was founded, became obscured by the actual force of the term itself. Instead of its being regarded as denoting only a relation between our conceptions corresponding to that between a thing supported and what supports it, the idea was suggested of an external objective reality, or even of a material nature, as implied by the term.

Rightly, however, to understand Aristotle's notion of Being, as it is the object of his Metaphysics, we should distinguish between Being as it is in nature generally, and as it is conceived in the human mind. For it is in this last sense that it must be understood, when it is stated to be the *object* of the universal science; since there is no other sense in which Being which is not in anything can be affirmed, but as it is the pure object of intellect, or exists in the intellect solely. Looking, then, at nature at large, we must apply Being, in its first and proper sense, to individual objects really existing; and, in a secondary sense, to the attributes of such: because, the first notion of Being in nature is suggested by the actual existence of the object; and our next notions result from the operations of our minds about the object already presupposed in existence. But the case is different when the objects whose being we are considering are pure objects of intellect in themselves. Here the abstract notions of things are the first in order:[1] these are, relatively to the mind, the realities about which it is engaged; whereas the actual objects in nature are, in this point of view, the secondary beings. The reason is, that an object of the mind, as such, exists in its proper nature when it is entirely abstracted from all matter, but loses that nature in proportion as it is viewed in any actual form of physical existence.

Hence, in the science of Metaphysics, the proper if not the only substance, or *ουσια*, is the form or abstract nature of things.[2] This, as explained by Aristotle, is the exemplar or representation in the mind of a thing as it exists in nature. As, then, the primary substances in nature are the things themselves as they are found and observed in nature, so the primary substances in the world of the mind are those abstract forms by which the truth and reality of things are there shadowed out. The science of Metaphysics, then, is strictly conversant about these abstract intellectual forms, just as Natural philosophy is conversant about external objects of which the senses give us information.

The object, then, of Aristotle in his Metaphysics is, to explain the nature of those general notions by which the mind represents to itself, and translates, as it were, into its own language, the objects without it, and speculates about them. Hence, in technical terms, he speaks of this science as the science of First Causes—the First Philosophy—or by the general titles of Philosophy and Theology. A science such as this, corresponds with what modern writers have designated the Philosophy of the Human Mind. They, indeed, have directed their attention rather to the powers and operations of the Mind; the study of which, in his view, belongs to Physics. He, however, has confined himself—in those books at least which, as a sequel to the Physical, have obtained, from that circumstance, the name of the Metaphysical—to the objects about which the Mind is immediately conversant.[3]

In this inquiry, Aristotle had to encounter two extremes of opinion maintained by philosophers before him—the doctrine of Protagoras, Empedocles, and others, who held that there was no fixed standard of thought—no absolute reality,—but that everything was relative to human perception; and the imaginative theory of Plato, which, by the hypothesis of self-existent Ideas, introduced a subtile materialism into the philosophy of mind, whilst, no less than the former theory, it made the external world a land of shadows and unrealities.

He points out the practical absurdity of the former opinion, according to which contradictories were equally true, and every proposition was equally true and equally false—by asking,[4] "why a man walks to Megara, and does not remain still, thinking that he is walking; why he does not go down a well or a precipice, as it may happen, the first thing in the morning, but appears to use caution, as not equally thinking the falling in to be good, and not good?"[5] Again, that men do not regard all notions as equally true, is plain, he observes, from this, that "no one who may have supposed himself during the night at Athens, when in Libya, walks to the Odeum."[6] He refutes, however, this sceptical doctrine more expressly, by distinguising between the reality of things as they exist absolutely or relatively to our perceptions. There may be no reality of Being, either in that which is perceived, or in the perception, these being affections of the percipient power. But it is impossible, that there should not really exist some objects externally, which produce the perception, and are independent of perception. Whereas those who make *Being* dependent on perception, by asserting that whatever appears is true, imply that nothing would exist if there were no living creatures.[7] Hence it appears that Aristotle virtually admits the distinction made by modern metaphysicians between the primary and secondary qualities of matter. He affirms, that whilst we have ideas of things without us which are simply our own perceptions, or acts of the perceiving mind, there must also be some really existing natures without us on which these perceptions are founded.

The Ideal theory of Plato tended to the same scepticism as the doctrine of these elder philosophers, but on a different principle. Plato destroyed all the certainty of our knowledge, by fixing the objects of it entirely out of the range of human intellect, and teaching men to abandon the information of the senses and experience, in the pursuit of abstract Ideas, the imaginary archetypes or exemplars of the things of the sensible world. He established in his system other beings separate from nature as the objects of philosophy; whilst his predecessors denied that there were any proper objects founded in nature. But both he and they equally removed all grounds of conviction from the mind of man. Aristotle, accordingly, strenuously combats the doctrine of Ideas as adverse to all sound speculation. He loses no opportunity, in the course of his discussions, of alluding to it and refut-

Theoretic Philosophy.

ing it.[1] He speaks of it as overthrowing all science, by multiplying, instead of reducing to certain definite principles, the variety of the objects of contemplation. "It is like," he says, "any one wishing to reckon, but who, thinking himself unable when he had less, should make more, and then reckon."[2]

The Ideal theory was, as has been before remarked, a modification of the Pythagorean theory of Numbers, or a mixture of logical and mathematical truth. Hence the importance assigned by Plato to Mathematics, as introductory to the philosophy of the Ideas. The theory of Pythagoras was, it seems, purely mathematical. It appears to have been an application of the properties of numbers to the solution of the phenomena of the universe. Plato proceeded a step further, and endeavoured more distinctly to account for the great variety of objects by the help of the abstractions of language. Still he retained so much of the mathematical conception as to make the knowledge of the Ideas dependent on the knowledge of mathematics; describing the objects of mathematics as intermediate to the Ideas and sensible objects.[3] Aristotle shews, then, in opposition both to the Pythagoreans and to Plato, that there are no such principles as Numbers or Ideas really existent in Nature as primary and constituent elements of things.

There is no point, in fact, on which Aristotle has spoken more plainly than in denying a separate existence to those secondary natures, which, in the language of the Schools, were afterwards called Universals. It is to individuals alone that he allows a real existence.[4] He remarks, that when any principle is asserted of several things, it is by analogy; as in fact there are distinct principles in each distinct thing; "for the particular is the principle of the particulars in each thing."[5] Thus, "whilst the universal man is the principle of man, Peleus is the father of Achilles—your own father of yourself." In things generically distinct, as colours and sounds, the principles differ, but are the same by analogy. In things specifically the same, the principles differ, not in species, but as they are distinct in each individual; *e. g.*, the matter, the form, and the moving power, are distinct in this and that man; but in the general principle, τῳ καθολου λογῳ, they are the same." So clearly has he laid it down, that none but individuals have a positive absolute existence, and that all other beings are relative to these, and results of the operation of our minds about them.

In extending our survey to the several subjects included in the metaphysical books, we must remember, that the science of which he is treating had hitherto been blended with logic under the general name of Dialectic. It was hardly to be expected, therefore, that Aristotle, in making the separation, should altogether forget the prejudice which had united them. Nor must we wonder, therefore, that much of the work should be employed in discussing the meaning of terms, and in observations addressed rather to the disputant in words, than to the inquirer into principles of philosophy. But we should be too hasty in judgment, if we condemned such discussions as foreign to the purpose of the metaphysician. The accurate examination of the notions expressed by such terms as being, oneness, sameness, contrariety, power, is illustrative of the connections of our ideas; for these terms are not dependent on the peculiarities of any one language, but are uniform characters of human thought. It is a curious and important inquiry, accordingly, to ascertain that connection of ideas of which these terms are the expressions; to trace, for example, the various modes of thought to which the term contrariety applies, or which are characterized under the description of qualities.

The inquiry, then, into Mind, considered in itself as a principle of life, and thought, and action, forms no part of Aristotle's Metaphysics. In his philosophy such an inquiry belongs to Physics; since he regards Mind only as a principle connected with matter. This inquiry he has prosecuted in a Treatise *On the Soul, or Life*, and in several smaller treatises *On the Parts and Motions of Animals*, *On Perception*, *On the Duration of Life*, *Youth and Old Age*, *Life and Death*, *Respiration*, *Memory*, *Sleep and Waking*, and *On Dreaming*. To these should be added the book *On Physiognomy*, and his larger work the *Treatise on Animals;* which, though properly a work of Natural history, is also illustrative of the nature of Soul, or the living principle in all animated, material beings. In these several works, there is less of mere speculation, and a more distinct evidence of that power of real philosophy, the δυναμις αναλυτικη, which he so eminently possessed. We find him stating and examining facts,[6] drawing from them conclusions in the spirit of a modern inquirer, though at the same time with the severe accuracy of his own method.

The ingenuity of the ancient philosophers was exhausted in attempting to assign the nature of the Soul or living principle. There was no one of the elements, except earth, which did not find its advocate in some theory of the Soul. It was represented also as a combination of all elements; or as blood; or intrinsic motion; or a harmony and conjunction of contraries. Aristotle, pursuing the method of his Physics, wisely avoids endeavouring to refer the soul to any particular class of material objects; explaining the nature of it, as it instances the union of the two principles, matter and form, in a common result. It is an instance of the principle of matter, so far as there must be an organized body susceptible of life in everything that lives. It is an instance of the principle of form, so far as that nature, in which the life of the creature consists, is perfectly developed in the animated body. His definition, accordingly, maintains the distinctness of body and soul[7] as two principles combined, without defining what the soul is in itself. He illustrates their union by the analogy of the eye and the sight.[8] There must be the eye in order to sight; but the eye, though perfect in its structure, is not an eye unless the principle of sight be superadded.

Thus, considering the principle of life as distinct from the organization with which it is connected, he proceeds to inquire into its laws, by examining the mode of its operation. He divides its mode of operation into five classes, according to the objects about which it is exercised. It is, 1*st*, a principle of nutrition, in which respect it is common to vegetables and animals; 2*dly*, of perception; 3*dly*, of appetites and affections; 4*thly*, of intellect; 5*thly*, of locomotion. Wherever there is perception, there are also, he states, appetites and affections;[9] and consequently all these modes of

(P. 709, Du Val.)

operation of the living principle are evidenced in brutes, with the exception of intellect, which belongs to man exclusively.

His observations on Perception are highly important, as tending to shew the existence of living powers in animals, distinct from the organs by which those powers are displayed. He affirms that there is always a medium interposed between the perceiving power and the object perceived,—appealing to the sense of sight. Sight, he observes, is not produced by placing the object on the eye, nor yet can be produced by the object itself at a distance. It must result, then, from something intervening between the eye and the object, so as to make an impression from the object on the eye. He mistakes, indeed, the nature of this medium, conceiving light to be the active development of the nature of transparency in some body, as in air or water,[1] and not material or capable of motion.[2] But the conclusion itself is just. And it serves to shew that the eye[3] perceives only as an instrument of communication with external objects to an internal power of the soul. The senses which appear to militate with this conclusion are those of touch and taste. For these seem to be produced immediately, without any interposed medium. But there is no reason, he argues, to conclude the flesh to be the feeling power in itself[4] because it acts instantaneously. For an artificial membrane spread over the body would produce the like instantaneous effect: and supposing the air to grow all around us, we should in like manner have immediate perception of all objects of sense, and thus appear to have perceptions of sight, and hearing, and smelling, by one sense.

Perception, then, according to Aristotle, is the power of the soul to receive immaterial impressions from material objects; as the wax receives impressions of a seal without the brass or gold of which the seal is made. The impressions thus received, he regards, as the basis of all our knowledge; insomuch that a creature destitute of perception would be incapable of understanding and learning. Touch[5] is the sense indispensable to existence, and the only one so indispensable. All the other senses, he says, have been added for the good and perfection of the animal—του ευ ἑνεκα. The sensations are distinct, however, from the ideas of the mind. The sensations in themselves are never delusive. The same thing is always sweet or always bitter. But the same sensations may be followed by different ideas in different minds. To a sick person, what is naturally sweet may seem bitter, or, from accidental position with respect to the spectator, an object may appear different from what it is; as, for example, the diameter of the sun. To the ideas thus formed immediately from Perception, Aristotle gives the name of phantasms; and the power of Perception thus modified he calls phantasia or Imagination.[6] The delusiveness sometimes attributed to the senses themselves originates in this faculty of Imagination consequent on sensation. Together with memory, it constitutes the whole intellectual nature of brutes. In man it furnishes the first notices in order to the operation of his intellect. By the operation of the intellect on these notices the first simple ideas are formed, from which the mind proceeds to its complex and general notions.

In considering the nature of the intellect, Aristotle introduces an important distinction between the mere capacity or faculty of knowledge, and the actual knowledge possessed by the mind; or between the intellect and the principles of the intellect. He employs the well-known illustration of "a writing tablet in which nothing is actually written," to distinguish the thinking faculty in itself from the thoughts with which it is furnished. But he does not suppose, as this illustration might suggest, that ideas are objects distinct from the mind itself. Where the object of thought is itself immaterial, as when the mind is reflecting on itself, there, he observes, the thinking power and the object of thought are the same.[7] He conceives, however, that the mind is capable of existing without thinking,[8] and consequently does not resolve the whole understanding of man into consciousness. Hence, according to him, whilst the passive intellect, or the mind, as it consists of principles with which the senses have furnished it, perishes, the active intellect, the power itself by which we think, exists in its proper nature when separate, and is immortal and eternal.[9]

It may be perceived, from this view of Aristotle's Theory of Soul, or Life, how far he acknowledged the Immortality of man. So far as the nature of man is purely intellectual, he conceived it capable of existing separately from matter, and in some sense divine. But so far as it consists of affections, which he describes as λογοι ενυλοι, principles *in* matter, he regarded it as mortal and necessarily perishable with the body. He pronounces nothing on the nature of that immortality which he thus attributes to the intellect, speaking of it in a rhetorical manner rather than with the precision of philosophy. At any rate, as only asserting an immortality of such an abstract and undefined nature, he seems not unjustly to have been represented as opposed to Plato on the doctrine of the Immortality of the soul.[10]

As Aristotle included under Physics animate as well as inanimate nature, he has carried the historical part of his natural philosophy into both these departments. His *History of Animals* has been already mentioned. It is the precious relic of an extensive work, for which the materials were furnished to him by the conquests and the magnificence of Alexander. This fact alone excites an interest in favour of the work. And this interest is fully sustained by the variety of curious information contained in it respecting the structure and the habits of animals, indicating a power of the most minute observation.[11] He is said also to have written a work on Comparative Anatomy. There are extant among his works further illustrations of the animal economy, in treatises on the motion, the walking, the parts, and the generation of animals. In inanimate nature he has explored the causes of meteors, comets, earthquakes, of the rainbow, and other phenomena of the atmosphere, in a work on Meteorology. He has also separately discussed the nature of Colours, and of the objects of Hearing.

To this catalogue must be added two works which do not strictly fall under either department of nature, *The Problems*, containing queries chiefly on subjects belonging to Natural Philosophy, with brief answers,—a curious work, illustrative of his vast reach of observation, and his extraordinary sagacity in searching out the reasons of things; and

[11] It was the authority followed by Pliny in his *Natural History*. Pliny, viii. 16, says in allusion to it, "vir quem in his magna secuturus ex parte præfandum reor."

a tract against the doctrines of Xenophanes, Zeno the Eleatic,[1] and Gorgias.[2]

In Mathematics he has left very little. The only treatises extant under this head are, *The Mechanical Questions*, and a book *On Indivisible Lines;* both very inconsiderable works. But he had been trained in the school of Plato, whose threshold was not to be passed by the uninitiated in geometry; and had attained a perfect skill in the method of mathematical investigation then known. We do not want, indeed, more proof of this than is to be gathered from passages in his Physics, in which we find him sometimes establishing conclusions by steps of mathematical demonstration.

Efficient Philosophy.

Dialectic, or Logic.

Aristotle, as was before remarked, was the first to separate the proper science of Dialectic or Logic from that confusion with Physics and Metaphysics in which it had been entangled and perverted. In doing this he laid the foundation of a sound and practical Logic. There was a basis of truth, he saw, in the doctrine of Plato, which referred our knowledge of all sensible objects to certain abstract universal ideas, the objects of pure intellect. But he saw also that Plato had entirely overthrown the right application of the doctrine, by imputing to these universals a positive and distinct being. Instead of treating them simply as principles of classification and grounds of knowledge, Plato's creative genius built the world out of them, resolving all other existences into these as the primary essences and causes of all things. Having stated, then, the proper nature of these universals to be that of conceptions of the mind, by which it represents to itself things, not in that variable character in which they appear, but as they really are, Aristotle further considers them, in the treatises of the *Organon*, as they are employed dialectically, or are subservient to discussion and the communication of knowledge between man and man. There was indeed another view of the application of abstract principles, and prior to that of their employment in discourse, remaining to be considered. This was their use in enabling the mind to connect the phenomena of Nature, or as they are the causes of a proper scientific knowledge. But the state of philosophy in his time did not lead him to such an inquiry. It was reserved for an age of more diffused civilization, and the adventurous spirit of Bacon, to display the principles of that analysis by which the mind arrives at sound general principles, and obtains a real science of Nature. The practice of colloquial discussion on questions of philosophy, recommended as it was by the instructiveness and interest of the conversations of Socrates, attracted the attention of Greek philosophers to the mode of producing conviction by tracing out the connections and consequences of given statements. Aristotle, accordingly, was diverted from the study of the method of Investigation, to explore the application of general principles to the business of Argument. In pursuing this inquiry, he has laid down the principles of a logical science, applicable to the inferences of the reasoner from probabilities, as well as the most rigid demonstrations of the mathematician.[3]

Dialectic, in its original sense (for the term Logic is only of modern use), is the method of deducing the probabilities on either side of a question, which is so framed as to involve one of two contradictory propositions in the answer, according as the affirmative or negative of it is taken.[4] The discussions to which the term Dialectic refers being carried on by a series of questions and answers, the design of the art was to furnish the means of sustaining these intellectual exercises, by supplying not only principles of correct reasoning, or rules of Logic properly so called, but various modes of proof and helps to the invention of arguments.[5] To have a ready command of propositions on any given point, and the objections against it, so as to be completely armed for debate, was the perfect accomplishment of the dialectician. This most obvious application of the science produced unfortunately, in the haste to supply arms for the disputant, instead of a philosophy of Reasoning, a misnamed science, conversant chiefly about the intricacies of verbal quibbling. Zeno the Eleatic, Euclid of Megara, and Antisthenes, took the lead in framing systems according to this view. Nor do the Dialogues of Plato, though rich in examples of reasoning, suggest any more just and exact method. Hence the Logic which prevailed at the time of Aristotle, and which, from the partial acquaintance with his writings, continued, even after his improvements in this branch of philosophy, to be the system of the Greek schools, was a mere collection of subtile points of argument, without any attempt to analyze the process itself of argument. His Dialectic is the reformation of that irregular and perplexed system. Whilst he adopts and explains the general notion of the science, as a method of defending or impugning an opinion, he takes a larger, more philosophical view of the subject; investigating the grounds, both in the nature of language and in the connections of thought, on which all argument must rest. Hence his just boast, that "with regard to the dialectical art, there was not something done and something remaining to be done,—there was absolutely nothing done; for those who professed the art of disputation resembled the rhetoricians of Gorgias's school: for as these composed orations, so the other framed arguments which might suit, as they imagined, most occasions. These their scholars soon learned. But they were in this manner only furnished with the materials produced by the art,—the art itself they did not learn." He goes on in the same passage to observe that "upon Rhetoric much had been written of old; but on syllogizing or reasoning, absolutely nothing; the whole of what he had composed on that subject was from himself;"—that he had "derived no benefit from former labours:" expressing his hope, accordingly, that what he had "left undone would be forgiven, and that what had been discovered would meet with a favourable acceptance."[6]

It is a singular fact in the history of science, that his labours in this arduous work should have suffered an unjust depreciation in modern times, by being estimated in contrast with the analysis of Bacon. According to his own challenge, and as the reason of the case suggests, they admit only of comparison with the efforts of his predecessors, and of the Stoics, who, though following him, wrought upon the ancient model of the science, and elaborated that to its perfection. If we compare the method of Aristotle with what is known of the wrangling discipline of the Stoics, we shall then judge with more fairness of the philosophical cha-

---

[1] So called in contradistinction to Zeno the Cittian, founder of the Stoics, from Velia in Italy, his birthplace.

[2] The treatise on plants edited with his works is acknowledged by critics not to be the work of Aristotle, but of Theophrastus. The treatise *De Mundo* may also be regarded as now decidedly rejected from the number of his works, as also the *Collection of Wonderful Narrations*, and perhaps the *Fragment on the Winds;* the internal evidence of these tracts being against their imputed authorship. It is probable that the works of Theophrastus were mixed with those of Aristotle, from the fact of Theophrastus having had some volumes of Aristotle's bequeathed to him, and having used them in the composition of his own.

Efficient Philosophy.

racter of his labours. His disciples were content to be ignorant of such a method as the Stoics taught,[1] though, from its untoward prevalence down to the time at least of Cicero, it has probably been confounded with that of Aristotle, and thus reflected its disrepute on his more scientific system. With the method, however, of Bacon, the Logic of Aristotle has no natural rivalry. In the period of literature preceding the researches of Bacon, it happened that ingenious men, with a natural devotedness to the studies by which their minds had been moulded, sought to resolve the mysteries of science by a profound Aristotelic philosophy. Thus were principles of physics and metaphysics mixed up with the theory of argumentation; as, on the other hand, principles belonging to argumentation had been previously applied to the analysis of nature. The writings of Aristotle were regarded as a kind of Scriptural philosophy, beyond which there was no appeal in controversies of science.[2] And when an authority of this kind is once established, it is easy to see that a mere verbal philosophy will soon follow. Expounding and commenting on the text of the master supersedes the questioning of Nature; just as a mere textual theology supersedes an enlarged study of the facts, and truths, and scheme of Divine Revelation. But this perversion is not to be regarded as the tendency of Aristotle's philosophy. Practically, indeed, he does not keep clear of the seductions of realism. But in him realism is only a *practical* infirmity. Theoretically, he was perfectly aware that "the subtilty of Nature far exceeds the subtilty of human intellect;[3] and that, accordingly, to ascertain *what* things *are*, we must know them otherwise than dialectically. He would have dialectical skill employed for the purpose of stating and examining the questions and difficulties belonging to a subject—not to supersede an acquaintance with phenomena.[4] He observes, that when, in inquiries concerning what a thing is, men are ignorant of the circumstances connected with it, they pronounce only logically and emptily;[5] thus pointing out the futility of applying an instrument of discussion to the real business of philosophical investigation. So far, then, as dialectical art, by sifting a question thoroughly, clearing up apparent inconsistencies, and pointing out where the truth lies, may be regarded as an organ of philosophy, so far Aristotle authorizes the inquirer to employ it. It may serve as the precursor and companion of investigation, but not as the substitute. And thus he describes it as a method of "trying," πειραστικη; whereas philosophy is a method of "knowledge," γνωριστικη.[6] It is quite opposite to his idea of dialectical art to suppose it capable of furnishing the principles of the several sciences. These, he expressly says, belong to the sciences themselves, by which they must be supplied to the dialectician according to the matter in hand.[7] To the philosophical *disputant* they are the *data* with which he sets out; or rather, so far as he is concerned with them, the hypotheses, which he proceeds to discuss in their various points of view, tracing their connection with, or opposition to, other principles.[8] Aristotle, therefore, evidently did not intend that the philosopher, as such, should rest in mere logical speculation. And though he has not provided in his writings an instrument of Investigation, giving only indirect hints of such a method, he supposes it resorted to in practice by the philosopher. His Logic, accordingly, instead of being put in contrast with the *Novum Organon*, is to be regarded as an auxiliary system, introductory to the latter, and tending to enforce its use.

The error of the Schoolmen in applying logical principles to the philosophy of Nature, arose from their misconception of the nature of philosophical truth. They do not seem to have been aware that philosophical principles are but expedients which the mind adopts for connecting and arranging the various objects of Nature. Otherwise, they would have seen that a science conversant about the connections of our notions expressed in language, could not suffice for the investigation, properly so called, of other sciences. When the facts of this science were reduced to certain principles, the whole object of the science was accomplished. The result would be a scientific use of thought and language for the purposes of debate and speculation. To carry this philosophy into other matters, was an incongruity like that of combining principles of mathematics and ethics.[9] There was at the same time a ground for their error, in the universality of language, as the medium by which the truths of every science are expressed; and its comprehensiveness and extent, as it has the power of signifying by single terms an immense variety of objects. These imposing attributes of language gave at least the semblance of philosophizing to their *a priori* speculations. But could they have studied the writings of their master in a freer spirit, their acute minds would have seen the real use to which the universality and comprehensiveness of language might be applied, without trespassing on the legitimate province of Investigation.

A slight consideration of the nature of language may suffice to show the proper business of the dialectician. Language is the record of the observations of mankind on the course of nature. It is, as it were, a popular philosophy. Whatever may be its origin—whether words be merely conventional signs, as Aristotle teaches,[10] or have a foundation in the nature of the things denoted by them—still, their application to observed objects and facts in Nature, is the result of the operation of the human mind; and words, in this use of them, are the creations of the intellect. The intellect takes up and applies the existing signs furnished by language, however derived, to mark and preserve for its future direction the dictates of its past experience. Thus, the application of the term "burning" to the observed effect of fire on a combustible body, is an act of the mind recording its experience of that effect. Having recorded its experience by this term, it thenceforth uses the term as a substitute for the actual experience. Proceeding on that fundamental law of human belief and action, that all things will continue in their observed course, it trusts to the word thus obtained as a guide to future conduct. It is sufficient to say that anything "burns," to give us a representation of the effect of fire, and direct us in our actions with regard to that thing. Accordingly, by the use of terms, observations, in themselves individual facts, are generalized. The term,

1 Cicero introduces Cato in the character of a Stoic, speaking of the Peripatetics as deficient in acuteness, "on account of their ignorance of dialectic." (*De Fin.* iii. cap. 12.)

2 Where a disputant quoted a passage from this philosopher, he who maintained the Thesis durst not say *Transeat*, but had either to deny the passage, or explain it in his own way. (Bayle, *Dict.*, art. *Aristot.*) He refers, in evidence of this, to the *Courses of Philosophy*, printed in the sixteenth century.

3 Bacon, *Nov. Org.* i. aph. 1.

4 He sometimes expressly adverts to the difference between conclusions drawn εκ των φαινομενων and εκ των λογων, as *De Gen. et Cor.* ii. cap. 10; *Eudem.* i. cap. 6.

5 *De Anim.* i. cap. 1, p. 617, Du Val.

6 *Metaph.* iv. cap. 2.

7 *Anal. Pr.* i. cap. 30; *Anal. Post.* i. cap. 1, 3, 9.

8 Bacon rightly describes the invention which belongs to Logic, in saying, "Inventio enim dialecticæ non est principiorum et axiomatum præcipuorum, ex quibus artes constant, sed eorum tantum, quæ illis consentanea videntur." (*Nov. Org.* i. p. 82.)

9 Aristippus complained of mathematical science, that it gave no account of goods and evils. (*Metaph.* iii. c. 2.) As unreasonable is the complaint of the barrenness of invention of the Aristotelian logic.

10 *De Interpret.*

Efficient Philosophy.

originally the record of a single experience, serving practically in the stead of a repeated experience, comes to stand for a number of individuals. From its practical application to a multitude of similar events, it obtains a speculative multiplication as the general expression of many particulars, or, in short, becomes a class-term.

It is thus that language may be regarded as a popular philosophy of nature. Each term denoting some observed object or event, is a general principle, connecting the several objects or events to which it admits of being equally applied. Whilst it practically enables us to judge and act in a number of individual cases, it also speculatively presents the means of anticipating a number of particulars, as notions implied in it; or, in other words, is a *theory* of the particulars which it signifies.

But when we have once obtained a variety of terms, thus representing in each of them a multitude of particulars, we can further generalize our observations by reflection on the notions themselves, and recording our observations on these, in like manner as on the real objects and events of nature. We then notice whether the notions implied by one term, are distinct from, or are included in, the notions implied by another: and, accordingly, we regard the terms respectively signifying them, as classes, either totally distinct, or more or less extensive. We observe, for instance, whether the terms, "man," "animal," "vegetable,"—all being records of our observations on nature,—give us information of the same particulars, or of others entirely different: and we find that "man" and "animal" are but different views of the same individual, as for instance of Socrates; whilst the term "vegetable" is no expression of any observation whatever on the same individual. We find that "animal" represents to us more individual objects than "man;" so we regard it speculatively as a class including in it "man;" and both the terms "man" and "animal," as classes entirely distinct from the class "vegetable," because none of the observations referred to in either of the former are the same with those referred to in the latter.

These principles of language are the data on which the logical system of Aristotle is constructed. It is evident, from the mere statement of them, that there is such a thing as a scientific application of language, and the notions which it expresses, to the purpose of argumentative instruction. It is thus clearly seen to act as an instrument of knowledge by its very nature, independently of any art in the use of it. And it is for the philosopher, therefore, to inquire how it acts in producing this effect.

Now, in order to such a science, the first step appears to be, to reduce *our various observations* on existing things into some definite classes. We thus bring them out of that perplexing infinity which defies all grasp of the intellect, and obtain a few general notions under which the whole intellectual world may be surveyed. These classes will represent to us the different forms or modifications of Being, so far as Being is capable of expression in language. The next step is to examine the principle of Classification in itself, and notice the varieties of form which it takes; as the observations that are made on any individual give us more or less extensive, more or less invariable and scientific, views of the individual. The first step leads us to the Predicaments or Categories, general designations under which all the various abstractions of the mind are conveniently arranged for the purpose of the logician. These constitute, as it were, the fixed land-marks by which he may know the limits of each notion with which he has to do in any discussion. They are the great sections in the geography of the intellectual world which it is his office to explore and describe. The next step leads us to the Predicables, or various modes of classing the same object. Here we enter on that part of the science which is purely logical. In the arrangements of the Categories, the inquiry is partly metaphysical, partly logical. We are there philosophizing on the notions of the mind in connection with language. But here, we examine the principle of classification evidenced in language, *in itself*, and endeavour to obtain comprehensive views of all the varieties of form under which it appears.

Thus far the science of Dialectic was sketched out before the time of Aristotle. The Pythagorean philosopher, Archytas of Tarentum, has the merit of having instituted those arrangements of the objects of the intellect, which Aristotle adopted under the title of *The Categories*. The authority, however, of Simplicius, the commentator in the sixth century, on which such a work is ascribed to Archytas, is extremely questionable. The truth appears to be, that the arrangement itself was of ancient standing in Greek Philosophy, but was unknown as to its origin. It may, however, have been derived through the Pythagoreans, whose mathematical studies gave a colour to all their speculations; as the tenfold division, corresponding with the decimal notation of Arithmetic, would indicate. Whilst the classification, then, was adopted by Aristotle, the discussion of it is evidently throughout his own; strikingly displaying that acuteness of discrimination which is a great characteristic of his mind.

The number of the Categories may be deduced from the following considerations. We may contemplate an object either as to what it is, or what it has; as to its nature, or as to its attributes. 1. If we contemplate it as to its being or nature, it may be regarded, 1*st*, either as a whole complex independent being in itself; or, 2*dly*, partially under some abstract peculiar point of view which still represents its nature, but only indistinctly and inadequately. Under both these aspects it is a being or substance that we contemplate. Being, then, evidently, is of two kinds—Primary and Secondary. Individuals and units, existing alone and independently, are primary beings—those natures which are abstracted from them, and which by generalization become universals, not existing independently of the individuals in which they are observed, are secondary beings. Being or substance, then, under this twofold division, constitutes the 1st Category. The remaining nine, which are the following: 2. Quantity; 3. Quality; 4. Relation; 5. Place; 6. Time; 7. Situation; 8. Habitude or Condition; 9. Action; 10. Passion or Suffering, are all so many different affections or attributes of Being. Each head then, is separately considered by Aristotle, and its limitation exactly drawn. The treatise being further introductory to the whole method of disputation, a method not simply of reasoning, but of producing conviction on any subject, he prefaces it with pointing out, in what sense alone one notion, or rather the term which represents it, can be logically predicated or said of another; and at the end, in that portion of the work which has been called the Post-predicaments, subjoins explanations of the notions "opposite," "contrary," "prior," "co-existent," "motion," "having;" as the terms denoting them were understood in the Greek language.

There is no distinct treatise of Aristotle on the heads of Predicables. This classification, like that of the Categories, is doubtless of ancient date in the schools of Greece. He assumes it as familiarly known, and where accordingly he refers to it with explicitness, it is chiefly to shew its application to the purpose of disputation; as in the first book of his Topics. Here we have nothing to do with individuals as such. We are in the region of universals, and the question is, by what differences they are characterized. Now universals, or the classes which they denote when expressed in terms, can only differ in respect of that which is contained under them. They may combine a number of individuals in one view, differing only numerically from one another; or they may combine several classes, and other classes again may combine these. Thus the ascent may be made continually to a higher class, above which no other appears. Take for

example an action. The first universal formed by abstraction from it might be the notion of Temperance; a second would be that of Virtue; a third would be that of Habit. The first then is a species; the second, as well as the third, is a genus, comprising, as each does, not only individuals, but classes under them. Again, when several such classes are combined in an ascending scale, there must be points of difference distinguishing the lowest, which is the species, from the genus immediately above it, and a lower genus from a higher genus. These points of difference then, also universals, constitute the class of Predicables called differentia, from the service which they perform in relation both to the species and the genus. And thus the genus and differentia put together are said to make up the species; and when stated in words, become the definition of the class to which it applies. But there are universals still of a different character from these. They are such as result from the investigation of any individual or class from tracing it in its relations and consequences, and circumstances. We thus obtain the two additional classes of "Property and Accident." The 4th head, Property, classes all those universals which respect indeed a given nature or being, but not the whole of it, including under it whatever may be observed to result from the three former classifications. The 5th head, Accident, is the general designation of any circumstances in which an object may be observed, which do not result from its being or constitute any part of its nature, but present it in a particular case, or as it exists at a given time or occasion.

This five-fold division (reduced by Aristotle to the four heads of Property, Definition, Genus, Accident, on the ground that Differentia is not distinct from Genus), had its especial importance in the ancient schools of philosophy, and in those of the middle ages. When logic, under the name of dialectic, was regarded as at once a method of philosophy and an art of disputation, there would be a demand for definitions; and questions would be raised as to what was the genus, what the species of the object under discussion; how it differed from others under the same genus—what were its properties—what its circumstantials. Accordingly, in that portion of the *Organon* which is strictly dialectical, *The Topics*, much of the work is conversant about these several heads. They are valid and useful principles to us, both for the purpose of exact logical division and definition in their application to the business of investigation and systematic development of a science. But for the process of Reasoning it is enough that the relative extent of the terms connected in the several propositions be explored, and to see that they rightly express the great fundamental relation of genus and species—or of class extending over class—the general over the particular—the more general over the less general.

In the Categories, then, we have the Metaphysical Being of things, so far as it is denoted by language, drawn out into its various modes, and distinctly characterized in each. In the heads or classes of Predicables, we have the Dialectical or Logical Being, or the various modes of existence created by language, through its power of comprising multitudes under single terms. If, for example, we say "Socrates is wise," the metaphysical being here asserted is an abstraction of the mind, coming under the category of Quality: we are speaking of Socrates, not as he is individually, but as the *quality* of wisdom exists in him. But in the same expression the dialectical or logical being asserted is, the existence of Socrates as an individual in the class to which the term "wise" belongs. And thus the verb *is*, as connecting the two extremes of a proposition, the subject and the predicate, is technically termed the *copula*.

It is highly important to observe this distinction between metaphysical and logical being; as the right understanding of the whole doctrine of propositions and syllogisms is dependent on it. Every proposition then, viewed logically, is the reference of one class of objects to some other class, in the case of an affirmative,—the exclusion of one class from another, in the case of a negative. The "being," or the "not being," is the being implied or not implied in a certain term. The schoolmen, unfortunately, neglecting the distinction here adverted to, and thus reverting to that confusion of logical and metaphysical science which Aristotle's whole philosophy had laboured to remove, included both kinds of being under the common term "universals." Evidently, however, it cannot properly be said of Being, as it is apprehended by the mind, that it is a universal. A notion of the mind is in itself an individual; and its extension to more objects than one is an effect of the mental power of generalization. But the logical being is by its very nature a universal; since a term, so far as it is a sign, comprises in its extent every individual that admits of being referred to it as a class.

Accordingly, to examine propositions logically, we have only to inquire into the relative extent, or relative exclusion, of the terms conjoined in it. In this point of view, all propositions, on any subject whatever, are reduced to four kinds;—Universal Affirmative, in which one class is affirmed of the whole of another; Universal Negative, in which two classes are mutually excluded; Particular Affirmative, in which one class is affirmed of some of the particulars included in the other; Particular Negative, in which one class partly excludes another. These are the only varieties of form under which any two classes of objects can be combined in affirmations or negations. Every proposition, accordingly, in order to be brought under the survey of Logic, must be referred to one or another of these forms, as the case may be. Hence we may proceed to examine these ultimate forms to which propositions are reducible, independently of the things themselves about which the propositions are; and draw from them logical principles applicable to every particular case. Thus, the form of a Universal Affirmative, "every A is B," in which the letters A and B are put as the representatives of any objects whatsoever, is the proper datum, from which the whole logical nature of any Universal Affirmative Proposition may be explored. So also with regard to the remaining abstract forms.

Aristotle, accordingly, in his treatise on *Interpretation*, and in the commencement of his *Prior Analytics*, has thus examined the nature of Propositions, and deduced practical rules by which their force as principles employed in reasoning may be readily ascertained.

It has been objected to him, that he resorted to these abstract symbols rather than to more familiar means of illustration, in order to leave the truths of the science partially veiled. There may be some truth in the assertion, that he did not intend his written works to be accessible to the public without oral exposition. But it does not apply here. The observation already made on the nature of logical being, may be sufficient to clear up any misconstruction on this point. The principle of classification, which is all that Logic, as the science of reasoning, is concerned with, could not be examined so scientifically and clearly in any other way as in that which expresses the principle itself nakedly. Every thing else is irrelevant to the matter in hand. So far as anything else is attended to in a proposition, so far the mind is diverted from the logical point of view. His use of symbols, therefore, is only an illustration of his accurate and perfect method of developing the science.[1]

In his *Prior Analytics* he passes on to the consideration of Syllogisms, or arguments logically viewed. Here it is that the logical theory is properly unfolded. Syllogisms are

[1] The use of unmeaning symbols in logic rests on the same footing as their use in geometry and algebra.

Efficient Philosophy.

the perfect developments of the theory of language, as language consists of signs expressive of Being,—manifestations of the general fact, that every term denoting Being is the representative of a class of observations more or less extensive, on some subject.[1] This theory is first intimated in the ordinary use of single terms. It is next more disclosed in the connections of terms *i. e.*, in propositions affirming or denying one term of another. It is lastly laid open in the syllogism, in which the principle of classification is fully exemplified as the tie of connection between two terms affirmed or denied of each other.

Since, then, the evidence of the connection subsisting between the terms brought together in any affirmation or negation is *the point* in every argument; it is evident that the reasoning on any subject whatever may be exhibited abstractedly from the particular subject about which it is. Terms can only be connected as they are classes more or less extensive, relatively to each other; and this relative extent is evidenced at once, as before shewn, by the abstract forms of the propositions in which they are connected. Three abstract propositions, accordingly, in which the terms whose connection is explored, are, first (*i. e.*, in the two premises), separately stated in their relation to some intermediate class or middle term,—and then in their relation to each other (*i. e.*, in the conclusion), as it is the result of their premised relations to the intermediate class,—will enable us, without reference to any other consideration, to judge of the conclusiveness of the argument. The Syllogism is nothing more than this abstract statement of an argument.

Aristotle examines all the varieties of form which arguments thus abstractedly stated, or syllogisms, admit; whether from the position of the middle term in the premises, or from the different combinations of the four great classes of propositions; pointing out, under what arrangement of the middle term, what particular modes of argument alone are valid. From his whole examination, the conclusion results, that, under whatever form an argument may be expressed, the principle of the reasoning is the same in every case; each instance developing the theoretic power of language, according to which every term, so far as it denotes Being, is a class, more or less extensive, of observations on the thing whose being it denotes.

This ultimate principle of all reasoning is commonly stated in the form of a theorem, enunciating that "whatever is predicated (affirmed or denied) universally, of any class of things, may be predicated in like manner of anything contained in, or signified by, that class." This is that form of it known by the scholastic designation of the "*Dictum de Omni et Nullo.*" From the mode in which this principle has been introduced in systems of Logic founded on the method of the school-authors, a prejudice has been excited against Aristotle, as if he had employed the principle in establishing the conclusiveness of arguments already granted to be conclusive. Aristotle, however, does not introduce the principle in any formal manner, as a dogma or *a priori* ground of logical truth. On the contrary, it pervades the whole of his system, as resulting from every part of his inquiry. He is only concerned to shew that every argument, however varied in its mode, or form, is reducible to a form by which the truth of the theory shall be evidenced in it. Syllogisms are not proved by the principle; but the principle itself is proved by the nature of the syllogism, as any other philosophical truth is deduced from varied observations and experiments. In short, by his reference to the principle, he does not *prove* the conclusiveness of a given argument, but *accounts* for it.

It is necessary to observe that most of the technical phraseology of modern treatises of Logic is derived, not from Aristotle immediately, but second-hand, from the scholastic expositors of his philosophy. These, in carrying the notions of his Physics and Metaphysics into the science of Logic, obscured, by the strange dialect in which the truths of the science were thus delivered, its proper nature as an art of language. Thus, according to them, we hear of the "substance," and "matter," and "form," both of propositions and of syllogisms, and other such misapplied designations. On the contrary, the technical expressions of Aristotle himself are extremely few, and those strictly appropriate to the subject, elucidating the characteristic nature of a science conversant about words as they are signs of thought. The scholastic method, however, from its long usurpation, has so ingrafted itself on our modes of writing and speaking, that some acquaintance with it is in fact become necessary to us at this day; and may so far, therefore, be regarded as constituting a legitimate part of modern logic. But when the cumbrous technicalities of this system are made a ground of objection to the Aristotelic logic, it may be explicitly answered, that these are not parts of Aristotle's system, as it is found in the original, but the refinements of his commentators.

Having pointed out the several classes of Syllogisms into some one or more of which every valid argument must fall, Aristotle, in pursuit of the adaptation of his method to the business of disputation, proceeds to shew the various expedients in argument resulting from the consideration of these abstract forms. This part of his subject is prosecuted through the remainder of the first book of his *Prior Analytics* and the second of the same treatise.

The examination of Syllogisms is followed up in the *Posterior Analytics* by an inquiry into Demonstration; and in the *Topics*, into arguments founded on probable premises. The full discussion of the Syllogism was premised by him, inasmuch as the syllogistic process is common both to demonstration and to probable conclusions; and accordingly, as the more general subject of investigation, claimed the first notice in a scientific treatise of Dialectic. Properly, indeed, being the only part of the science which is really universal,—belonging to argumentation *as such*, under whatever form, whether by induction, example, or enthymeme (all of which are only different modes of expression of the syllogism), and whether the premises assumed be necessary or probable,—it is the only province to which the science of Reasoning, in its strictest sense, extends. In examining further the nature of demonstration and of probability, we depart from the rigorous limits of the science of Reasoning, and approach those of Rhetoric. But it is useful, at the same time, to examine these subjects as detached from Rhetoric, and in their connection with Logic; so far as we then confine our attention to the mere force of different kinds of argument on the *understanding;* whereas Rhetoric combines also the view of them in their effect on the *will.* We then consider them as they are capable of producing either knowledge or opinion; whereas in the latter case, we look at them in that complex result which is implied in persuasion. It was for the former purpose that they were required for the disputant: and thus it is that the consideration of them forms an important part of the several dialectical treatises which pass under the name of the *Organon.* For the same reason the concluding treatise on *Sophisms* is directed not only to the solution of Fallacies which may exist in the syllogistic process, or in reasoning, strictly viewed as reasoning, but to such also as may be traced in arguments where the process itself, the pure logic of the case, is perfectly correct.

The discussion of Demonstration is an exposition of the nature of Science, Επιστημη, as it was understood by the ancient philosophers. They restricted the application of the

[1] A *proposition* that is false is truly a proposition, whereas what is called an *invalid* argument is strictly no argument at all, because it does not exemplify the classification implied in the logical connection of terms.

Efficient Philosophy.

term to the knowledge of necessary truths; such truths as, when known, were known at the same time to be incapable of being otherwise. Aristotle, then, is employed, in the *Posterior Analytics*, in discussing the nature of the principles on which Science, as it was then understood, must be built.

Here he had to encounter perplexities and misconceptions introduced into the subject by the Platonic philosophy. In Plato's system knowledge was mere reminiscence. It was a penetration of the mind through the veil of sensible things interposed between itself and the realities of the intellectual world—its return to those purer perceptions which it had enjoyed before its present union with a body. This doctrine was altogether founded on a fallacious view of the nature of Demonstration. Because in Demonstration the conclusion is necessarily implied in the premises, it was conceived that a science or proper knowledge of any particular was in all cases founded on a knowledge of the general principles in which it was implied. But this was an inversion of the actual order of knowledge, which commences with the particular, and ends in the general. In mathematical and metaphysical science the two things coincide; the notions of our mind being, on the one hand, in themselves particular facts, from which we may argue to general principles; and, on the other hand, in their application to the business of philosophy, being the general principles of our knowledge. But Plato argued from this coincidence in these sciences in general, and therefore confused Demonstration with the scientific arrangement of facts. Aristotle, we find, was not free from the same fault in his Physics; but in his theory of Demonstration he has strictly provided against it. He has here pointed out the difference between the proof of matter of fact and matter of abstract speculation. Instead of inculcating the necessity of establishing every conclusion in Science by syllogism or a demonstrative process, he shews that all Demonstration proceeds on assumed principles; which principles, accordingly, must be obtained from observations generalized, and not by a process of reasoning from the general to the particular.[1]

There is one part of the work which deserves a more particular notice, as throwing light on his whole method of philosophizing, while it shews how far he approximated to the Induction of modern philosophy. To obtain an accurate notion of the being of any thing, we require a definition of it. A definition of the thing corresponds, in Logic, with the essential notion of it in Metaphysics. This abstract notion, then, according to Aristotle, constituting the true scientific view of a thing,—and all the real knowledge consequently of the properties of the thing depending on the right limitation of this notion,—some exact method of arriving at definitions which should express these limitations, became indispensable in such a system of philosophy. But in order to attain such definitions, a process of induction was required—not merely an induction of that kind which is only a peculiar form of syllogism, enumerating all the individuals implied in a class instead of the class itself—but an induction of a philosophical character, and only differing from the Induction of modern philosophy so far as it is employed, not in the limitation of facts, but of the notions of the mind in their expression by words.

There are, then, two kinds of Induction treated of by Aristotle. The first, that of simple enumeration. Its use is, where we have not beforehand ascertained a class to which we may refer the subject under consideration, and the search is in fact for a middle term. In this case, then, a collection of all the individuals which are supposed to make up the class, serves instead of a middle term. Assuming, accordingly, that these individuals are equivalent to the class, we draw the conclusion, that what has been affirmed or denied of each of these collected individuals may be affirmed or denied of the class, or the universal which they represent. This, then, is nothing more than a syllogism. There is no process of investigation involved, but it is assumed, that we have found the assertion made, true in all the individual instances; and the induction itself is simply the process of bringing them under a common principle.

But there is also a higher kind of Induction employed by Aristotle, and pointed out by him expressly in its subserviency to the exact notions of things, by its leading to right definitions of them. As it appears that words, in a logical point of view, are classes, more or less extensive, of observations on things, it is evident that we must gradually approximate towards a definition of any individual notion, by assigning class within class, until we have narrowed the extent of the expression as far as the case requires.[2] The first definitions of any object are vague, founded on some obvious resemblance which it exhibits compared with other objects. This point of resemblance we abstract in thought, and it becomes, when expressed in language, a genus or class, under which we regard the object as included. A more attentive examination suggests to us less obvious points of resemblance between this object and some of those with which we had classed it before. Thus carrying on the analysis,—and by the power of abstraction giving an existence to those successive points of resemblance,—we obtain subaltern genera or species, or subordinate classes included in that original class with which the process of abstraction commenced. As these several classifications are relative to each other, and dependent on the class with which we commenced, the definition of any notion requires a successive enumeration of the several classes in the line of abstraction; and hence is said technically to consist of genus and differentia; the genus being the first abstraction, or class to which the object is first referred, and the differentia being the subordinate classes in the same line of abstraction.

Now, the process by which we discover these successive genera in forming a definition, is strictly one of philosophical Induction. As in the philosophy of nature in general, we take certain facts as the basis of inquiry, and proceed by rejection and exclusion of principles involved in the inquiry, until at last,—there appearing no ground for further rejection,—we conclude that we are in possession of the true principle or nature of the object examined; so in the philosophy of language, in drawing forth an exact outline of any notion, we must proceed by a like rejection and exclusion of notions implied in the general term with which we set out, until we reach the very confines of that notion with which our inquiry is concerned. This exclusion is effected in language by annexing to the general term denoting the class to which the object is primarily referred, other terms not including under them those other objects or notions to which the higher general term applies. For thus, whilst each successive term in the definition, in itself, extends to more than the object so defined, yet all viewed together do not; and this their relative bearing on the one point marks out and constitutes the being of the thing.[3] This is thus illustrated by Aristotle:—"If we are inquiring," he says, "what magnanimity is, we must consider the instances of certain magnanimous persons whom we know, what one thing they all have so far forth as they are such; as,—if Alcibiades was magnanimous, or Achilles, or Ajax,—what one thing they all have; say 'impatience under insult;' for one made war, an-

Efficient Philosophy.

other raged, the other slew himself: again, in the instances of others, as of Lysander or Socrates,—if here it is, 'to be unaltered by prosperity or adversity;'—taking these two cases, I consider, what this 'apathy in regard to events,' and 'impatience under insult,' have the same in them. If now they have nothing the same, there must be two species of magnanimity."[1] So, again, he suggests a similar process in order to ascertain the nature of anything. He directs that the investigation should commence from the genus; since, having discovered the properties or sequences of the genus, we have also the sequences to the next class in the series,—and so on from that class to the next below in order,—until by this continued process we reach the individual object examined. In the course of investigation, also, he observes, that we should attend to whatever is common, and examine to what class of objects that belongs, and what classes fall under it;[2] and for the same reason select analogies; since, in both these instances, we obtain genera, under which the object investigated may be arranged. The process is virtually the same as if we should investigate a fact or law of nature. But the Induction of Aristotle, having for its object to determine accurately in words the notion of the being of things, proceeds, according to the nature of language, from the general, and ends in the particular; whereas the investigation of a law of nature proceeds from the particular, and ends in the general. In the process each kind of Induction is an analysis. But logical Induction is synthetical in the result, whilst philosophical induction is analytical throughout. The former labours to particularize as much as possible, counteracting the uncertainty occasioned by the generalizations of language, whilst the latter is engaged in penetrating the confused masses in which objects first present themselves to the mind, and exploring their most general and characteristic form. Thus the induction of Aristotle was strictly επαγωγη, or the bringing in of notion on notion, each successively limiting the application of the preceding one in regular series, so as at length to present a distinct notion of the object defined.[3] The notion thus obtained in words is the *logos*, or expressed reason of the being of the thing; and hence perhaps the prevalence of the name Logic[4] as appropriate to this branch of science, instead of the more general and ancient designation of Dialectic,—which expresses rather the application of the science to the ancient mode of disputation, than its philosophical nature.

It would appear, then, that Bacon has not done justice to Aristotle in the contemptuous manner in which he has spoken of the Induction taught by Aristotle. It is certainly limited in its design, as having chiefly in view the correct statement of the particular notions on which an inquiry turns, rather than the discovery of new truth: and it is not set forth with that fulness of method with which Bacon enterprised the *Novum Organum*. But it is sound and valid so far as it reaches; and it shews that Aristotle was not intent on corrupting philosophy with Logic, but rather on applying Logic to that very purpose which Bacon himself so much insists on—the bringing the intellect even and unprejudiced to the business of Science. Of the application of Induction in its full philosophical extent, Aristotle presents abundant specimens, and particularly in his treatises on Ethics and Rhetoric. His discussion of the Passions in the latter treatise is a masterpiece in that way. He sets out, indeed, abstractedly with definitions of the several passions, but these are the results at which he has arrived by Induction; being obtained, as his subsequent observations shew, by a close interrogation of Nature; by examining accurately what belongs, or does not belong, to each particular passion,—and thus eliminating its exclusive character and proper nature.

Rhetoric.

As the Speculative Sciences had been confounded under a vague notion of dialectic, so had Rhetoric, in the ostentatious study of it prevalent before the time of Aristotle drawn into its system the practical sciences of Politics and Ethics. Observations had been accumulated on the mere accessories of the art; but the proper business of the rhetorician—the inquiry into the argument itself of which a composition must consist—had been overlooked. Aristotle had therefore to dig a foundation for the fabric of a real science of Rhetoric. He had to clear away misconceptions; to shew the data on which Rhetorical science must proceed, and the relative importance of its several parts.

He commences, accordingly, with pointing out the nature of its connection both with Dialectical and Moral science. It is first and most directly connected with Dialectic, inasmuch as it is a general method of providing arguments on any subject whatever. As Dialectic examines and discusses the principles of various sciences, considering them in their relations as principles in the abstract, and not as the principles of this or that science, and is so far equally conversant about all subjects; so Rhetoric inquires generally into the nature of the principles of Persuasion, and therefore is also of equal application to the various subjects of human thought. In the discussion of these abstract principles under the head of Dialectic, it is found that they are referable to two general classes—that they are either probabilities or necessary truths. And Aristotle, accordingly, after having explained the nature of Syllogism, or the more general connection of principles, which is independent of their peculiar nature, proceeds to investigate the nature of deductions as drawn from necessary principles or from probabilities. The consideration of this distinction anticipates in some measure the province of Rhetoric, touching on the point, as has been observed, in which Rhetoric differs from Logic strictly so called. As the science of eloquence, its office is to speculate on the effect of different principles in producing persuasion, and not simply on their abstract relations; and therefore it must examine the force of arguments, whether probable or necessary, in their influence both on the judgment and the will. Principles, in short, as they are grounds of Credibility, and not as they enter into a reasoning *process*, constitute its proper subject. In this respect it coincides with a part of the ancient Dialectic. But it differs, again, from Dialectic, inasmuch as it is connected also with Moral Science. In Dialectic the force of man's moral nature on his opinions is not considered. Will such or such a conclusion result from such or such arguments, according to the procedure of the human intellect in forming its judgments? is the whole inquiry of Dialectic. But Rhetoric further considers, what is the practical force of such and such arguments? what effect are they found to have in actual experience?—not according to their mere speculative truth, but as acting on the complex nature of man. Practically, it is found that questions are not examined on their positive merit as simple questions of truth, but with feelings and sentiments thwarting or aiding the discernments of the intellect. Here, then, is opened a wide field for a philosophical inquiry of a peculiar character, distinct from Dialectic, and yet strictly founded on it, and implying it throughout, as well as of the highest importance in order to the success of truth in the world. This inquiry is what Aristotle institutes under the head of Rhetoric.

He has evinced the most perfect comprehension of the nature of the science which he had undertaken to develop, in holding it, as he does, in exact balance between the two sciences of Dialectic and Morals with which it is associated.

[1] *Anal. Post.* ii. c. 13, p. 175, Du Val. [2] *Anal. Post.* ii. c. 14. [3] *Anal. Prior.* ii. c. 23.

[4] Aristotle uses the adverb λογικως, as in *Met.* vii c. 4, and elsewhere; but not the noun λογικη to denote the science, and only Διαλεκτικη.

Efficient Philosophy.

There is much of logical matter in the course of his inquiry, and still more of ethical. But he never suffers us to forget that we are not examining those sciences *in themselves* under the head of Rhetoric, but in their relations to a science compounded of both. He would have the rhetorician versed in Dialectic, and deeply acquainted with human nature. But he is intent on shewing how he is to apply his knowledge of both these sciences to the proper business of Rhetoric—the influence on the heart and mind of the person addressed. It is not a vague and popular knowledge of those sciences which he is inculcating throughout, but a popular application of authentic principles drawn from them both, and a popular application founded on a deep philosophy of human nature.

This philosophy consists in an investigation of the kinds of Evidence by which the minds of men are commonly swayed in accepting any conclusion proposed to them, and of those principles of their moral nature which generally induce belief. The whole, accordingly, is an inquiry into what is probable, or rather what is credible and persuasive, to a being so constituted as man.

Rhetoric, then, does not consider arguments as they are abstractedly necessary or probable. Such arguments appeal to the intellect alone; and the result from such is, either a full conviction, or a presumption of some point in question. Rhetoric, on the other hand, looks to probability in the *result*. Whether an argument be necessary or probable in *principle*, is comparatively of no consequence to the rhetorician, provided it be persuasive in its *effect*. He has to consider, therefore, only a probability of this kind—on what grounds men commonly *believe* an argument to be just, or are *influenced* by any statement.[1] Now men are found to receive arguments as conclusive on two different grounds—from considering them either as logically sound, deducible from admitted principles, or as coincident with some previous observation or fact. Hence the distinction between probability and likelihood; probability denoting conclusions proved by some reason alleged; likelihood denoting conclusions grounded on matter of fact, the conclusion being something like what has been experienced. Aristotle distinguishes these two kinds of rhetorical arguments as probabilities, εικοτα, and signs, σημεια. The precise nature of the distinction he explains more fully in his Analytics.[2] In his Rhetoric he directs our attention rather to those practical forms which the two classes assume in Enthymemes and Examples; Enthymemes being probable arguments which state a conclusion with the reason of it, but without the formality of a syllogism; such as occur in familiar use; Examples, arguments in which a conclusion is drawn from particular facts or observations.

He points out, accordingly, the force and propriety of Enthymemes and Examples, as modes of producing conviction, both in themselves, and relatively to each other, according to the subjects in which they may be employed. And as Enthymemes are the more comprehensive head—for, in fact, every argument from Example is in principle an Enthymeme, the example cited being the reason of the conclusion,—he dwells more explicitly on the nature of Enthymemes. These he distinguishes in respect of the principles from which they are drawn. These principles may be, 1. Entirely abstract, unconnected with any particular subject, and equally common to all subjects; or, 2. They may belong to particular subjects, and the sciences of those subjects. Instances of the former class, called by the general name of Topics, or common places, are conclusions of the possibility of any thing from abstract considerations of possibility,—of the existence of anything from the existence of that which implies it more or less, &c. Instances of the latter, ειδη, or specific Topics, are conclusions drawn from the nature of human actions, or from some principle of government or commerce, or whatever it may be to which a speaker or writer has occasion to refer.

The matter of proof, or the grounds of Credibility in themselves, being obtained, it comes, in the next place, to be considered how this proof is acted on and modified in the result by the complex nature of man, on whom the result is to be produced. The subjects then, to which rhetoric properly applies, are those in which there is some opening for the action of the moral feelings. In questions of pure science the intellectual powers alone are concerned. There is no personal application to the individual; no reference to his own experience for the proof of the principles, as is the case with all inquiries involving human conduct; where a fairness of judgment is as much required in order to an acknowledgment of the principles, as a clearness of intellect. Whatever may be the nature of a mathematical enunciation or a fact in chemistry, when it is once stated and proved, there is no question whether we approve or disapprove it. Its truth is suffered to rest on its proper footing. But a conclusion respecting our own nature, or involving our own conduct, immediately calls all our moral principles to the survey of it. Our hopes, and fears, and wishes, are heard pleading for or against it. Here, then, is the proper province of the rhetorician. He is to furnish principles to the advocate by whom the case is to be laid before these internal judges; to suggest how to prepare the evidence for their reception; and by his knowledge of their former judgments, to enable him to present the truth before them in such form, that it may obtain a fair hearing, and be affirmed in their decisions.

For the convenient arrangement of rhetorical arguments, Aristotle divides Rhetoric into three different kinds, according to the different occasions on which it was employed among the Greeks:—1. The Deliberative, or its use in political debates; 2. The Judicial, or its use in popular assemblies, as those of Athens, in which the people collectively exercised the judicial functions; 3. The Demonstrative, or its use in panegyric and invective, when the orator had to gratify his hearers by the display of eloquence.[3] In these several heads of inquiry he has given an admirable account of the motives by which mankind at large are commonly actuated in their conduct and opinions. And here we should notice the peculiar complexion which the Happiness and the Virtue, described in this part of his philosophy, assume. He is led to speak of Happiness[4] as the great object of human desires—the point from which all views of expediency obtain their colouring. Here, however, he is not concerned to illustrate that Happiness to which the aim of mankind *should be* directed, but that which is *in fact* sought in the world as it is. He therefore portrays those various forms with which self-love commonly invests the idea of happiness. For it is evidently more to the purpose of the orator, whose object is to carry his point, to conform his arguments to the views entertained by his hearers, however theoretically false, than to a more just theory, of which they have no conception. Virtue, again, is here a law of Honour.[5] It is an appeal to those right feelings which exist in the nature of man, by which virtue is approved and vice disapproved. Independently, however, of discipline and cultiva-

[1] When it is asserted, that Dialectic is concerned about truth, and Rhetoric about opinion, this must be understood to mean that Rhetoric has for its object to discover, not what any particular thing *is*, but what will give a *persuasion* or *belief* that it is. At the same time, those principles on which such a persuasion depends, are real truths about which the science is conversant.

Efficient Philosophy.

tion, these feelings are not found in fact always duly exerted. There is ground, therefore, for a popular kind of Virtue, in a philosophical survey of those principles by which the human heart is *commonly* swayed in its decisions of right and wrong. This popular law of right is at least an approximation to perfect virtue. It is an irregular and uncertain application of the criterion of approbation, which belongs to true virtue alone; leading to a preference of the more ostentatious virtues to the less obviously praiseworthy; and to the exaltation of some qualities merely specious, or even faulty, to the rank of virtues, through the want of discrimination and corruption of principle in the world. Thus Virtue becomes, in the popular view, a power of benefiting others,[1] rather than an internal habit of self-moderation. Men acquiesce in that general notion of it, under which it most strikes their attention, and calls forth their admiration. Such, then, is the kind of Virtue to which the orator must make his appeal. He cannot calculate on finding the bulk of his hearers moral philosophers, or persons whose sentiments have been highly cultivated. He must therefore proceed on those broad principles which may be presumed to exist in the heart of every man though imperfectly cultivated. It is to these he must conform his arguments, if he would produce that impression which he desires.

Further, as the habits of thinking and feeling among men are found to be affected by peculiarities of circumstances, it is necessary for the orator to have studied also the varieties of human character, and to have reduced these to general principles for his practical direction. Aristotle, accordingly, has not lost sight of this point in his Rhetoric, but has shewn a keen observation in the outlines which he has given of the effects of different governments, different periods of life, different worldly fortunes, in modifying the human character.

He had strongly condemned former rhetoricians for making the whole art consist of an appeal to the Passions. At the same time, he was aware that such an appeal was a necessary part of the orator's address; and that no arguments, no merely intellectual proofs, could avail, independently of this. To overlook, indeed, the affections in arguments concerning human conduct, is to disregard the authorities to which the whole process of proof is ultimately addressed. Wherever evidence is not absolutely irresistible, and there is room for doubt,—though the object be simply to induce belief,—the hearer naturally proceeds in his analysis of the evidence, until he brings it home to himself, and finds it issuing in something natural to his own character and feelings. This it is that at last determines the wavering balance. The philosophy of Rhetoric, therefore, required some outlines to be given of these ultimate arbiters of all rhetorical questions. And we are indebted accordingly to his masterly view of the subject, for an accurate and beautiful delineation, in the course of this treatise, of the leading Passions of human nature. Of its excellence as a specimen of the Inductive method of philosophizing we have already spoken.

In treating both of the Virtues and of the Passions, Aristotle's view was to enable the orator, not only to recommend his arguments to the moral sentiments and feelings of an auditory, but to bring also to their support the natural and just prejudice from Authority. We involuntarily ascribe to one who appears in the character of an instructor, the advantages of superior knowledge and kind intentions. The prejudice in favour of Authority is thus reasonably founded on a respect for wisdom and virtue. It is important, then, to the orator to avail himself of this prejudice. There must be nothing to counteract, in those addressed, the natural tendency to believe the speaker. On the contrary, his whole address must conspire to this end. It must give the impression that he is a man of intellectual ability, as well as of right sentiments and feelings. Hence Aristotle deduced a distinct class of rhetorical proofs under the head of, 1. *Ethos*, or character; 2. The *Pathos*, or appeal to the passions; and 3. The Demonstration, or argumentative proof as such, constituting the two other heads. He thus shews, on the whole, how a speech may at once carry conviction, interest the feelings of the hearer, and give the weight of personal authority to the speaker.

In the popular views of Rhetorical science, the subjects of style and method engross an undue importance. We are thus led to think that eloquence consists in the skilful use of the ornaments of style, in the flow of periods, and the structure of a composition advantageously distributing its lights and shades. The attention is diverted from the material itself of eloquence, the strong framework of argument, without which no eloquence can subsist. Aristotle, in proceeding to the discussion of style, has cautiously maintained the subordination of this part of Rhetoric to the proper business of the art—Persuasion; treating it as a necessary condescension to the weakness of the hearers. If, however, the manner in which we express our thoughts may contribute to the reception of our assertions and arguments, and it be allowed that the principles of Taste are real parts of the human constitution,—the consideration of style must necessarily enter into a philosophical system of Rhetoric. The effect of the style is part of the whole result of the composition on the mind of the hearers, and is so far, therefore, an ingredient in that Probability or Credibility about which Rhetoric is conversant.

In conformity with this view of the importance of style, Aristotle lays down perspicuity as the great principle of good composition. It is with him "the virtue of style."[2] All the ornaments of language, whether from the structure of periods, or from the various modes of thought by which a point, or a propriety, or a dignity, or an animation, is imparted to a subject, are explained in reference to this fundamental law.

Nor has he left unconsidered the arrangement of the parts of a speech; though this also was in his opinion scarcely a legitimate portion of the art. Former rhetoricians had encumbered their systems with numerous artificial divisions, giving precise rules for the composition of each distinct head. Aristotle's more exact method admits no other divisions than the Proposition and the Proof; the former founded on the necessity of stating the subject of discussion, the latter on the necessity of proving the point stated: though he afterwards allows the convenience of a fourfold division into, 1. The Proem or Introduction; 2. The Proposition; 3. The Proof; 4. The Epilogue or Peroration.

So deeply and fully has the science of Rhetoric been considered by Aristotle. His treatise on the subject, the *Rhetoric*, in three books, addressed to his disciple Theodectes, and his *Nicomachean Ethics*, are perhaps the most perfect specimens of systematic sciences extant in ancient or modern literature. For extent and variety of matter, the *Rhetoric* may be ranked even above the *Ethics*. It has been justly characterized as "a magazine of intellectual riches. Nothing is left untouched" says one who could well appreciate the value of the work, "on which Rhetoric, in all its branches, has any bearing. His principles are the result of extensive original induction. He sought them, if ever man did seek them, in the living pattern of the human heart. All the recesses and windings of that hidden region he has explored; all its caprices and affections—whatever tends to excite, to

[1] *Rhet.* i. cap. 9, αρετη δε εστι μεν δυναμις, ὡς δοκει, ποριστικη αγαθων και φυλακτικη· και δυναμις ευεργετικη πολλων και μεγαλων, και παντων περι παντα.

[2] *Rhet.* iii. 2. *Poetic.* c. 22.

ruffle, to amuse, to gratify, or to offend it—have been carefully examined. The reason of these phenomena is demonstrated; the method of creating them is explained. The whole is a text-book of human feeling; a storehouse of taste; an exemplar of condensed and accurate, but uniformly clear and candid, reasoning."[1] It is professedly adapted to the business of the orator, that being the original occasion of an art of Rhetoric. But it is in fact a body of precepts for good writing, furnishing authentic principles of criticism in every department of prose composition. His smaller treatise in one book, entitled *The Rhetoric to Alexander*, the genuineness of which is questionable, is more strictly a science of political eloquence, being written, as the introductory address would intimate, in obedience to the King, who had requested a work of that description.[2] The same philosophical views of eloquence may be traced in this work; but more popularly set forth, with less of technical precision, and more of illustration from examples.

Poetics.

No work of Aristotle has been more justly estimated than the fragment which has survived to us under the name of his *Poetics*. Imperfect as it is, it has been uniformly regarded as the great authority of the laws of criticism in poetry: subsequent writers having only extended and illustrated the principles laid down in it. The excellence of this little work, which is only one book of the three of which the whole treatise is said to have consisted,[3] shews how much we have to regret the entire loss of his other works on the same subject. The treatises *On Tragedies* and *On Poets*, mentioned in the catalogue of Laertius, probably contained much valuable information concerning Greek writers, whose works, perhaps whose names in some instances, have not been transmitted to us.

That portion which time has spared of the *Poetics*, is almost exclusively confined to the consideration of dramatic poetry. But the philosopher, with his usual depth and reach of thought, has here laid a broad foundation of principles applicable to the whole subject. He derives the nature of poetry in general from the principle of Imitation inherent in man. Two natural causes, he says, appear to have originated poetry; the natural power of imitation,—and the pleasure which all men take in imitation, that is, in recognizing likenesses between distinct objects. These two causes thus stated by him are in fact but one principle: the pleasure resulting from imitation being the principle itself of imitation, viewed in its tendency or proper effect, the production of pleasure: though, in the language of his philosophy, the first would be the motive cause, the second the final. The science then termed Poetics, is that which treats of the method by which the natural principle of Imitation obtains its proper and full expression; or a collection of observations on the mode by which pleasure is produced in imitations of which language is the instrument. Hence the business of the Poet is stated by Aristotle to consist in representing things, not "as they have been, but as they ought to be;" and therefore is described by him as of a more philosophical and excellent nature than that of the historian.[4] The pleasure of Imitation will not be answered, unless a likeness be recognized between the objects and events described, and the objects and events observed in the general course of nature. Otherwise it will be a mere pleasure in the execution, or in some circumstance of the work. The poet, therefore, in order to accomplish the end of his art, must possess a philosophical power of observation. He must have compared objects and events, and detected points of resemblance, and thus formed for himself general principles on which he may proceed to model his ideal world. At the same time he differs from the philosopher much in the same way in which the orator differs from the dialectician. He has not to consider what is *abstractedly* like in things, but what will be viewed and felt as like in its *effect* on the sentiments and feelings of men. Therefore it is that his creations are clothed with a beauty and loveliness surpassing nature. The resemblances which he shadows out partake of those hues, which the imagination, and the feelings, and every beautiful and noble sentiment of the heart of man, reflect upon them.[5]

These fundamental notions of the art pervade the system of Aristotle's Poetics, though, from the briefness of the work in its present imperfect state, they are by no means fully developed in it. In the work, indeed, as it now is, the basis of the poetic imitation—the actions, passions, and manners, of which a poem is descriptive—are exclusively considered; and we have no inquiry, as in the Rhetoric, into the principles of human nature by which the pleasure resulting from the imitation is modified in its effect. From this circumstance, as well as from his accounting for the pleasure of poetry on the ground of a natural delight in tracing out resemblances, Aristotle has been sometimes thought to have placed the excellence of a poem in the mechanism of its story,[6] and to have neglected altogether the intrinsic poetry of thought and expression. But we shall not do justice to the comprehensiveness of his views, if we estimate them by the limits of the present work. He seems here to have premised only, what ought naturally to occupy the first place in a philosophical system of the art.

It must be remembered, also, that Greek Poetry was essentially dramatic. It was expressly composed with a view to public recitation or exhibition; and in poetry of this kind, the character of the incidents would hold a much greater importance than in poetry intended chiefly to be read. The incidents would here hold a place analogous to the thoughts and expressions of the poem submitted to the contemplative study of a reader. This may further account for Aristotle's laying so much stress on the interest of the plot in Tragedy

The definition of Tragedy given by Aristotle is remarkable, as savouring more of the spirit of Plato's philosophy than of his own. Describing its nature as it differs from Epic poetry and from Comedy, he further characterizes it as, "by means of pity and fear, accomplishing the purification of such passions."[7] The purification of the soul was the object to which Plato directed the noble enthusiasm of his philosophy. By converse with the ideas of the intellectual world, he would have the soul disenchanted of the spells which bound it to sensible objects, and cleansed of the impurities of its earthly associations. Aristotle's description of the effect designed in tragedy, applies this doctrine to the particular emotions of the soul produced by pity and fear. His idea appears to be, that Tragedy, by presenting the objects of those passions, without the grossness and the violence with which they are attended in actual life, teaches us to feel the passions in that degree only in which an impartial spectator can sympathize with us. By familiarity with these pure abstractions—the true philosophy of the passions so called forth—a moral effect is worked on the heart; the mimic occasions on which it is rightly exercised serving as a real discipline of purification.

7 *Ibid.* c. 6, δἰ ελεου και φοβου περαινουσα την των τοιουτων παθηματων καθαρσιν. So, again, in his *Politics*, viii. 7, he speaks of "purification" as an effect of music. There he promises to explain his meaning when he comes to treat of poetry; but no explanation occurs in the Poetics.

The question, on what the peculiar pleasure of tragic incident depends, is not distinctly considered by Aristotle. But it may be accounted for on his principles; from the view already given of the purification effected by tragedy, and that which he elsewhere gives of pleasure as the result of every affection rightly exerted. That moderation of the passions of pity and fear which tragedy has for its aim, is that due exertion of them to which pleasure has been attached by nature. There is nothing then to disturb or interfere with the pleasurable emotion; as happens when those passions are excited in the real occasions of life.

Practical Philosophy.

Ethics.

It has been already observed, that under the head of Practical Philosophy, Aristotle treats of those sciences which are conversant about the goods of human life. According to this view, the practical sciences are reducible to two: 1. Ethics; by which man is furnished with the principles belonging to his natural good as man; 2. Politics; which inquires into the principles on which the constitution of Societies may be made subservient to the same end. Economics ought perhaps to be stated as a third branch of science under this head. But in the view of Ancient Philosophy, it naturally falls under Politics; inasmuch as it strictly means the regulation of families; the family being considered as the commencement or element of the association of men in cities and states.[1]

In taking a review of Aristotle's Ethical system, it would be injustice to the philosopher to withhold the expression of admiration of the real wisdom displayed by him in this department of science. We are little aware, living as we do in the sunshine of gospel-truth, what a reach of thought it required, in those times, to see the science of Ethics in its proper light, as a discipline of human character in order to human happiness. The ethical writings of Aristotle, composed amidst the darkness of heathen superstition, abound with pure and just sentiments. Instead of depressing man to the standard of the existing depraved opinions and manners, they tend to elevate him to the perfection of his nature. They may indeed be studied, not only as an exercise of the intellect, but as a discipline of improvement of the heart; so much is there in them of sound practical observation on human nature. They are directed, it must be allowed, solely to the improvement of man in this present life. But so just are the principles on which he builds that improvement, that we may readily extend them to those higher views of our nature and condition to which our eyes have been opened. And no greater praise can be given to a work of heathen morality, than to say, as may with truth be said of the Ethical writings of Aristotle, that they contain nothing which a Christian may dispense with, no precept of life which is not an element of the Christian character; and that they only fail in elevating the heart and the mind to objects which it needed Divine Wisdom to reveal.

He has left three principal treatises in this department of philosophy, familiarly known by these names: 1. The *Nicomachean Ethics*, or Ethics addressed to his son Nicomachus, in ten books;[2] 2. *The Magna Moralia*, in two books; 3. *The Eudemian Ethics*, or Ethics addressed to Eudemus, in seven books; besides a short popular tract (probably a summary by another hand), *On the Virtues and Vices*. *The Nicomachean Ethics* exhibits the most formal and complete development of his theory, and is the work on which his fame as a Moral philosopher is chiefly rested. The other treatises are entirely coincident with this in the views taken of the subjects discussed, and often coincident also in whole passages.

It is well known with what eager but unprofitable subtilty the inquiry into the Chief Good was prosecuted by the Greek philosophers. The speculation proceeded from a misapprehension of the nature of Moral Philosophy. They thought, consistently with their method in Physics, that, as every action of human life appeared the pursuit of good, there must be some common principle of good, the constituent of the moral nature of Actions. Again, as the object pursued when attained becomes an end in which the action rests, occasion was given for inquiry into the Ends of actions, and comparing them, and finding out the ultimate End. Hence they were busied in exploring the several objects of human pursuit, and drawing conclusions as to their relative goodness and finality in the order of pursuit. It is easy to see what a field for ingenuity was opened in determining the point where the two notions of the Best and the Final coincided; and in this consisted the determination of the *Summum Bonum*, or Chief Good.

Now Aristotle examined human Actions with a more philosophical eye. He readily saw through the vain realism of those speculations which supposed either some one Idea of Good, or some common quality of good to exist in every thing that was called good.[3] He was aware, also, that when the "ends" of action were spoken of, it was not with reference to some ulterior object, as was implied in all those theories which laid down a speculative definition of the Chief Good; but that it was the very nature of a Moral Action, to be *in itself* an End.[4] Hence he turned aside from that track of inquiry which had misled his predecessors, with the exception of Socrates, and struck out for himself a new path of Moral Science. He has thrown his preliminary views, indeed, into a form resembling that of the speculative moralists, in unconscious deference to the prejudices of the method in which he had been trained. Thus he sets out in his *Nicomachean Ethics* with a sketch of the Chief Good as the final and perfect end of all Actions. And this may give the idea, that in reading this work we are examining a system of the same kind with the Greek Moral Philosophy in general,—a view of it which Cicero[5] appears to have taken; since he speaks of Aristotle's having united two objects as together making up the Chief Good of man. On looking, however, closely into his actual investigation, we find it very different in its pursuit; the agreement being only in the technical form of the argument.

The Chief Good[6] which he is intent on establishing is, the principle or general nature of Actions as such. He investigates, that is, the law according to which Actions attain the good which is their object; and which, as being the *end* really designed in all Actions, whatever may be the immediate particular end sought in each, is the great final cause of all—the End of ends. He speaks of moral virtue as conversant about Affections and Actions, περι παθη και

[1] Theophrastus is probably the author of the first book of the treatise of *Economics*, edited among the works of Aristotle. (Niebuhr's *Hist. of Rome*, Transl. vol. i. p. 15.) The latter part of that book, indeed, does not pretend to be more than a restoration of the Greek text from a Latin translation. The second book is acknowledged to be spurious.

[2] His son Nichomachus has been represented as the author of some of the books of this treatise. Cicero (*De Fin.* v. 5) is inclined to allow him this credit, but without any good reason.

[3] *Eth. Nic.* i. c. 6; *Mag. Mor.* i. c. 1, 2.

[4] *Ibid.* vi. c. 2, 5, x. c. 6; *Polit.* vii. c. 3, 13; Cicero *de Fin.* ii. c. 22, "Id contendimus, ut officii fructus sit ipsum officium."

[5] *De Fin.* ii. c. 6; see also Euseb. *Præp. Evang.* xv. c. 3 and 4.

[6] Laertius mentions, in the Catalogue of Aristotle's writings, a treatise, περι τἀγαθου, in three books.

Practical Philosophy.

πραξεις.[1] In strictness, however, Actions, or Affections as they are exerted in act, are the only proper subject of Ethics; which is conversant about Affections, inasmuch as Affections are implied in Actions. Actions are Affections exerted towards some object, and comprehend, accordingly, both external and internal acts,—as well those which are only known to the conscience of the agent, as those which are open to the observation of men. An action, then, according to Aristotle, is good, in which an Affection attains its object; and, in that case, the Action itself may be regarded as a τελος or End; the Affection being realized, completed, satisfied, in it. Accordingly, it may be inquired, how the Affections really obtain their objects, when exerted towards them, or in action; or what constitutes an Action an End. But this is a very different inquiry from one that, by comparison of particular objects, searches after some definite sole object of pursuit. In this it is presupposed, that every object of a natural Affection is an ultimate end, or an object in which that Affection, whatever it may be, when exerted rests, as in its natural good. It is sought, then, to ascertain how this is so; what that principle is, by which any Action whatever is really a Good in itself and an End. Such a principle is analogous to the Chief Good of the speculative moralists; because it exhibits Actions in that point of view in which their *goodness* consists, or in which they accomplish that good towards which the Affections naturally tend. But it differs, so far as it restricts the notion of the Chief Good to no one distinct class of objects. It is simply a general account of the right constitution of man's moral nature exemplified in the multitude and variety of individual instances of Actions. As Newton does not inquire what Gravity is, but develops the law by which it acts; so Aristotle does not give an abstract notion of the Chief Good, but explores the principle by which it is realized in human life. He thus obtains a view of it independent of any speculative opinions concerning the Chief Good or Happiness of man. His theory leaves the notion of Happiness entirely relative.[2] The philosopher and the uneducated, the rich and the poor, the barbarian and the civilized, each individual, in short, under whatever modifications of human life he may be conceived to exist, must, so far as he obtains the good attached to the exertion of an Affection, or performs a perfect Action, exemplify that law, or ultimate principle, which constitutes an Action a perfect Action, or Good.

His several treatises of Ethics consist of a development of this his characteristic view of human good. He had observed how mankind, through the force of passion and evil habits, mistake and pervert their proper goods. Ethical philosophy, he thought, might be applied to correct this misapprehension of men—to reform this perversion. The force of sound practical instruction, at least, might be tried. He wished therefore to propose to their view the real goods intended for them by the constitution of their nature, and to call the attention of each individual to the pursuit of these in his own particular case. His design throughout accordingly is, to direct the principles of man's moral nature towards their proper objects in such a way that they may rest in these objects as *ends*, and thus attain the proper good of man. When all the principles are so regulated that this effect takes place in each, the collective result is, in such a case, Happiness, or the entire and consummate Good of man. Whence he takes occasion to describe Happiness in general terms, as "Energy of Soul," ψυχης ενεργεια,[3] or "the Powers of the Soul exerted in act" "according to Virtue," or, if there are several virtues, "according to that which is best and most perfect." The mode of description is drawn from his physical philosophy. It is founded on a notion of some intrinsic power in the soul working like the operations of the natural world. His theory of Happiness, then, contemplates this process of the soul at its termination, where the proper nature of the Soul as an *Active Principle* is fully developed. The truth is, we have then a general fact, representing the result in all particular instances in which an Affection is found properly and effectually exerted in act. He takes, indeed, into his estimate of the Chief Good, the effect of the circumstances of the world on the virtuous exercise of the powers of the Soul; adding to his description the condition of "a perfect life,"[4]—or an adequate duration of life, and adequate opportunities,—for the development of the moral principles. This, however, is but to assert, that the law by which man attains the Happiness of his nature, must, in order to be judged of truly, be contemplated in its *tendency*—in the effect that it would realize, if it acted freely, without impediment from the world. To think that external goods are causes of happiness, he says, is like imputing the excellence of the music to the lyre rather than to the art of the musician. Prosperity, he also observes, has its limit in reference to happiness, since it may be *excessive*, and in that case would be an *impediment* to happiness.[5] This necessary qualification of the expression in his sketch of the Chief Good, gives the appearance of his including prosperity to a certain extent as a *constituent* of the Good. Whereas in this point, as well as in the whole form of his inquiry into the Chief Good, he is only following the abstract method of Ancient Philosophy. In reality he is pursuing a course of investigation strictly inductive. The terms themselves, "a perfect life," carry on the idea of the soul's working out its perfection, in which process the perfection of its physical existence would necessarily constitute a part.

Thus, too, the notion of Pleasure, considered as an abstract good, is distinctly examined in his Ethics.[6] The practice of Ancient Philosophy obtruded the question on his notice; whether Pleasure was to be identified with happiness, or was to be regarded as an evil. He accordingly formally discusses it; refuting the existing opinions on the subject, and establishing, that pleasure is a good, so far as it necessarily accompanies the exercise of every natural principle; and consequently, that the highest pleasures are attached to the exercise of the highest principles. The discussion itself is thrown into a form highly abstruse and speculative. But the conclusion at which he arrives is entirely practical, and of the greatest importance in order to a just theory of Virtue. It amounts to this, that the mere gratification of every natural Affection, by its exertion in action, is not to be distinctly proposed and aimed at as the end of that Affection. This would be to grasp at the result, and neglect the means in order to it.[7] For, the gratifica-

[2] The observations of Paley on "Human Happiness" (*Mor. and Pol. Philosophy*, B. i. ch. 6) are an excellent illustration of Aristotle's Theory,—shewing as they do, that there is no one notion of happiness common to all men and all states of life; and that consequently it is vain to attempt to define the notion of happiness.

[7] It may be illustrated thus: Suppose, in travelling, some place were pointed out to us in the distance. We may imagine that we shall arrive at it by making it our immediate object, and shaping our course directly towards it. But such a course might lead into insuperable difficulties; whereas by going along the road leading to it, though circuitous and indirect, it will be safely and surely reached.

Practical Philosophy.

tion is, as explained by him, the mere *result* of the adaptation of the affection to its object,—something accruing and *consequent* on the attainment of the object,—not the object itself. It is the completion of the process of nature involved in an Action.[1] The attainment, therefore, of the highest pleasure attached to our nature, presupposes that the perfect work of Virtue has been performed, in adjusting the Moral and Intellectual Principles to their objects.

In proceeding to expand this outline, or "type" as he calls it, of his Ethical system, Aristotle appears to have adopted the language of the Pythagoreans, according to which Virtue was defined a "Disposition or Habitude of Propriety;" or that state of man's moral nature in which all the Affections are in their due measure and proportion. Analyzing the moral principles into, 1. Affections, 2. Powers, and, 3. Dispositions, he rejects the first two classes of principles as inadequate to the production of Virtue; and directs attention to the Dispositions as its proper seat. He observed that the Dispositions were subject to modification by custom or habit,—that a moral character did not precede, but resulted from moral actions; and that a character so formed alone enabled one to act morally. As it was thus evident that virtuous habits were the bond of connexion between virtuous action and virtuous principle in the agent, he concluded, that the principle by which the soul "energized,"—by which its Affections were perfectly exerted in act,—was, in its general nature, a Disposition, or Habitude, influencing the Choice.

He had observed also, that in every instance in which Good resulted from the exercise of the Affections, due regard was had to the person of the Agent, to the occasion, to the matter in hand, to the persons respected in the action, to the purpose, &c.; that thus, the virtuous character consisted in its power of due adjustment to all the circumstances of the case in every action. On the ground, then, of this general fact, he further concluded the nature of Virtue to consist "in a *mean* relatively to ourselves,"—relatively, that is, to the individual agent in each instance.[2] The abstract mode of expression is a continuation of the same physical notion under which his theory of the Chief Good is represented. The soul, when truly virtuous, is conceived to be wrought to a temperament or mean state, all its Affections and Actions being in their due proportions to one another, and to the whole nature and circumstances of the individual man.

To determine, however, this due measure of the Affections, is the great question of Ethics. An exercise of Reason is implied in the adjustment of the Affections and Actions, so as neither to exceed nor fall short of the due measure on each occasion, and of that particular function indeed of Reason which is conversant about the affairs of human life, and which we call Prudence. Aristotle, accordingly, includes in his outline of Virtue, the statement that "the mean" must be "defined by Reason, and as the prudent man would define it." Still the question remains, what is the standard of adjustment —what the criterion of the mean, as a mark to which the moral aim is to be directed?

Now, the instances in which this self-moderation belonging to the character of virtue is observed, become in themselves the objects of Approbation, exciting in us sentiments of love, esteem, admiration, honour, sympathy, &c. Hence the various expressions introduced into Moral Philosophy, of fitness, propriety, proportion, the decent, the fair, the honourable, the amiable, the expedient, &c.; the adoption of one or more of which tests of the morality of Actions, has given its peculiar complexion to different systems. Aristotle contemplates these sentiments of Approbation, not as they are in themselves, but as they are outwardly evidenced by the Praise accompanying certain Actions.[3] It is clear that men commonly praise some actions and censure others. Where men—not any particular class of men, but society at large—agree in praising any action,[4] there the action so commended may be regarded as good in itself, and an evidence of virtuous principle in the agent. The approbation thus signified was expressed in the Greek language by the term καλον,[5] to which we have no perfect counterpart in our language, though the word "honourable" if understood in its full meaning, may sufficiently represent it.

Aristotle proceeds to apply this criterion to the discrimination of the several virtues; a distinct class of objects of the Affections constituting in his system the ground of a distinct virtue.

His enumeration of the virtues is incomplete. It is, however, chiefly intended as an evidence by induction, of that moderation of the affections—"the mean"—in which the nature of Virtue consists. His division, indeed, of Virtue is physical rather than logical—an enumeration of the *parts* of virtue rather than of the *kinds* of it. His method, accordingly, did not require of him a complete statement of all the particulars comprised under the general term Virtue. He has been accused of attending chiefly to the splendid virtues. He was probably led, by the very criterion which he employed, as well as by his view of the connection between Ethics and Politics, to sketch more prominently those particular virtues which recommend a man in society. And thus he has sketched beautiful outlines of those charms of familiar intercourse—affability, frankness, agreeableness.[6] His introduction, indeed, of these qualities among the virtues of his system, is a striking evidence of the practical nature of that virtue which he inculcates. It is a virtue which is not to be forgotten in any part of a man's daily life. Whilst it nerves his arm in dangers, distributes his bounty, shields him against temptations of pleasure,—it unbends him in the hours of leisure, and is ever on his tongue, whether gravely pronouncing in his assertions and judgments, or playing in the sallies of his wit. These very instances shew that he did not regard splendour as the exclusive attribute of virtue. On the contrary, he expressly speaks of it as the heightening and decoration of the several virtues, and as excellent because it presupposes all other virtues in their perfection.[7] Another evidence of his not being exclusive in his regard to the more showy virtues, is his treating of Gentleness.[8]

He selects the virtue of Justice[9] for more particular discussion. He distinguishes it as a particular virtue from the whole of Virtue, which it denotes *relatively*,—in its being the moderation of the love of gain or self-interest. Seduced, however, by the example of Plato, he departs, in his mode of treating this virtue, from the strict province of Ethics into that of Politics. The Justice which he explains is a political virtue, applicable to the citizens of a common state, rather than to man as man. And this confusion of ethical and political justice has led him into a speculative refinement, which

Practical Philosophy.

---

[1] Pleasure, accordingly, is defined by Aristotle, in his *Rhetoric*, i. 11, physically, as "a kind of motion of the soul, and a full and perceptible constitution into the proper nature."

[9] Among his lost treatises was one *on Justice*, in four books. (Diog. Laert.)

Practical Philosophy.

involves a difficulty in reconciling the notion of Justice with his theory of Virtue. Looking at Justice as a dispensing power, he observed that it was concerned about "a mean," in things themselves, in apportioning to each person his exact due, whether of reward or punishment. On the ground of this fact he points out that Justice is not "a mean," as the other virtues are, but is "of the mean"—not in itself "a relative mean," but "relative to a mean." Had he considered Justice solely as a moral habit; he would have seen that the distinction was unnecessary: since in this point of view it conforms precisely to his general notion of virtue in being a principle of self-moderation. There is, however, a foundation for the remark in the circumstance, that Justice admits of greater exactness in its exercise than other virtues. "The rules of Justice," says an excellent writer,[1] "may be compared to the rules of Grammar; the rules of the other virtues to the rules which critics lay down for the attainment of what is sublime and elegant in composition." In the other virtues we are thrown more on our sense of propriety in forming our practical decisions. In justice we have evident facts before us—the merit or demerit of individuals in themselves; and these form an external standard to guide us in our conduct, over and above our internal convictions of right. So far, then, Justice may be regarded as "of the mean," besides being also a point of propriety, or a mean within ourselves. Aristotle, it should be observed, had no other more appropriate word distinct from "Justice" to express "honesty" or "integrity," and consequently was led to generalize too far in his analysis of Justice.

Aristotle's discussion of Friendship[2] is open to similar objection. He has considered it in its outward effects as a social principle akin to Justice—to which Justice is subordinate and supplementary—rather than as an internal ethical principle, the moderated exercise of benevolence in the heart itself. His observations, however, on the subject admirably illustrate the importance of Friendship to the right constitution of society—the various modifications of the benevolent principle in the different relations of human life—together with the peculiar amiableness of virtue in itself. In the last respect, indeed, the discussion forms an essential part of his Moral Philosophy, as it tends to show his conviction that the moral principles have their seat in the heart.

Indeed, this part of his Ethics, as well as his inquiry into Justice, should be accurately studied by all who would obtain just views of the comprehensive character of the Virtue of his system. Together they comprise a body of relative duties. Under Justice would be classed the duties of "religion, memory of the dead, filial reverence, patriotism, civil obedience, veracity, honesty," &c.,[3] so far as these duties flow from *claims* on our respect, and are prescribed by human laws; under Friendship, the same duties as they are prompted by sentiment and feeling, and are known by the names of piety, gratitude, benevolence, fidelity, generosity, &c. Hence the character of Virtue, in the little compilation on the Virtues and Vices which passes among his works; that "it is of Virtue both to benefit the worthy and to love the good; and to be neither apt to punish nor revengeful, but merciful, and placable, and indulgent: and thus there follow on Virtue, kindness, equity, candour, good hope; moreover, such qualities as, to be domestic, friendly, social, hospitable, philanthropic, and a lover of what is honourable."[4]

His theory, then, of Virtue must be regarded as involving a minute and distinct attention to all the particular virtues. And herein appears its great excellence, as contrasted with those of some modern philosophers, who have endeavoured to trace up all the virtues to some one principle of our nature, as benevolence, or self-love, or prudence. All such theories are in truth mere accommodations of language, by which different classes of phenomena are arranged under the same terms; the effect of which is to give a shadowiness to the form of virtue, instead of striking it out in distinct outline. Aristotle's theory is the law by which these different principles are held together in fact—the common process by which the operation of each virtue is carried on; and which, when realized in the character of a man, gives him the command of all the virtues.

The ancient Moral Philosophy sought, like the Modern, to resolve Virtue into some *one* principle. But the endeavour of the ancients was chiefly to ground it on some *Intellectual* principle. Socrates contended that the virtues were instances of Prudence or Knowledge, *φρονησεις*, or *λογοι*, or *επιστημαι*. Aristotle shews the foundation of this misconception, in explaining in what respect the production of virtue might be regarded as the work of the intellect. Each virtue consisting, as he shews, in the adjustment of the action to all the circumstances of the case, the virtue of an action must depend on the practical judgment of the individual agent; and an agent who is uniformly virtuous must exhibit this practical judgment uniformly operating, enabling him readily to decide on the point in which the virtue of acting lies.[5] This operation of the intellect on moral objects he designates as the intellectual virtue of Prudence or Wisdom.[6] When he speaks of it as "defining" or bounding the mean in which virtue consists;[7] he implies that, as a speculative definition presents to the mind an exact notion of the thing defined, so the principles supplied by Prudence give clear perceptions of the moral nature of an Action. For example, suppose a man to have received some evident wrong—some injury done to him without provocation. The Affection of Resentment naturally leads him to requite the injustice on his assailant. But by what method of action he should do so, is a matter of question. He must know exactly in what way his Resentment should be shewn, in order to act virtuously; besides having, as his general principle, the inclination to act virtuously.[8] He must, therefore, have had some experience of human life—some practical knowledge of the nature of Actions which have been generally approved as fulfilling the end of this Affection. An experience, then, of this kind, applied to the exercise of all the Affections, and operating invariably on the conduct, constitutes the Prudence of Aristotle's system. It is thus intimately connected with the moral principles, as the moral principles are with it. It is the combined result, in the intellectual part of our nature, of all the virtues of the heart; as, on the other hand, Prudence is the diverging of the intellect through the various virtues of the heart. Hence his conclusion, that it is impossible to be properly good—*κυριως αγαθον*—without Prudence; or to be prudent without moral Virtue; and consequently, that all the Moral virtues are inseparable, inasmuch as the possession of all is requisite for the perfecting of Prudence,[9] and with Prudence they all follow.

In this account of Prudence is to be traced the principle of Moral Obligation involved in Aristotle's theory of Virtue. He considers the Moral virtues as those of the inferior part of the soul, and therefore as formed to obey; whereas the intellectual principles, as being purely rational, have, as such, an intrinsic authority. Prudence, accordingly, being the intellectual virtue employed in conjunction with the

moral in the production of Virtue, is, from its nature, supreme over its associated principles, and demands of right their submission to its dictates.[1] It must be confessed that such a ground of obligation is merely theoretic; and so Aristotle himself perceived it to be.[2] As a principle of observation and reflection, it resembles in some measure the supremacy of Conscience; but it does not come up to the force of that master-principle. Conscience rewards and punishes by its judgments, carrying with it a sense of merit and demerit; whereas the dictates of prudence carry no such sanction in them. Properly, however, the notion of "Obligation" is inapplicable to his system. Not inculcating Morality as a law, but as a philosophy, or art of life, he was not called upon to shew why it should be obeyed as a law. It was enough for him to point out, from observations on human conduct, that it is in fact obeyed by all who attain their real good.

But though the principle of Conscience has no place in his theory, it is certainly implied in his test of virtue and vice—the praise and blame of mankind. The universal consent of mankind on these points he regards as decisive of the Moral nature of an Action. But this is to allow a standard of right and wrong inherent in human nature, or what is equivalent to a Conscience. If all agree in praising a certain modification of the Affections, and in blaming another, it is clear that there must be some common principles in all to serve as the bases of these unanimous judgments. The same conclusion results from his admission of Dispositions or Capacities of virtue, and of the existence of natural virtue, in man, antecedent to the proper formation of it in the character. Indeed, his analysis of Prudence is decisive of his real view of this point. Not only are the principles on which Prudence is to speculate to be drawn from the heart; but the very deduction of these principles to the particular cases of conduct involves moral perceptions. For how else is the precise point in which the "mean" lies—in which the due measure of the Affection exerted consists—to be ascertained? If the virtue of the Action consisted in an absolute mean, a mere intellectual process, such as that of Arithmetic or Geometry, might ascertain it. But the mean in question being neither more nor less than what is *proper*, this implies a sense of propriety. Right conduct, according to him, is not such because it is neither excessive nor defective; but is neither excessive nor defective because it is right. This is plain from his induction of the several virtues, in which he shews that there is a "mean," because there is a point of propriety; so that a Moral perception must precede every decision on Moral questions. It is of the greatest consequence, in order to a right understanding of his account of Virtue, to observe this necessary dependence of the knowledge of the "mean," on the adjustment of the moral principles to their objects. The want of attention to it has led to absurd objections against Aristotle's theory. He has been interpreted, as if he had said that we could have *too much* courage, *too much* liberality, &c.; which notion proceeds on the false assumption, that the mean laid down by Aristotle is a *quantity;* whereas it is only a proportion or correspondence existing between the principles of the agent and the objects of those principles.[3] The term "mean," in fact, as employed by Aristotle, is merely negative, marking the exclusion of all unchastened, inordinate, or undue feeling from the character of Virtue.

But though his system is defective as an authoritative law, it develops a much nobler theory of duty than the philosophy which rests our obligation to virtue on a ground of interest. The "Prudence" of Aristotle's Ethics must be understood as widely different from the prudence of such a theory. The Prudence which he teaches is no calculation of consequences. It is a practical philosophy of the heart; inseparably connected with the love of that conduct which it suggests. Whereas, when we are taught to act on the ground of interest, the prudence then inculcated is a mere intellectual foresight of consequences, independent of any exercise of the heart.[4] Such a system, whilst it overthrows the distinction between right and wrong as a fundamental principle, requires either a very comprehensive power of intellect in order to its practical adoption, or an express revelation from the Deity, declaring the good and evil consequences annexed to particular actions. These are conditions which sufficiently expose its futility as a sole guide to duty. The heart of man leaves far behind this morality of consequences, and decides, even before the action itself has its birth, whether it is morally right or wrong. The appeal to the revealed will of the Deity is not only a *petitio principii*, inasmuch as no will of the Deity can be ascertained and proved divine, without the previous admission of principles of right and wrong; but is refuted by the simple fact, that theories of Virtue, such as that of Aristotle, have been devised by men who had no positive belief in a Divine Providence. Independently of the excellence of such theories, the mere fact of their *existence* as accounts of Human Duties is sufficient for the argument. That "the difference, and the only difference," between an act of prudence and an act of duty is, "that, in the one case, we consider what we shall gain or lose in the present world—in the other case, we consider also what we shall gain or lose in the world to come;"[5] —is an assertion, disproved at once by the fact, that Aristotle saw a difference between the two acts, independently of that consideration on which the notion of duty is there made to rest. Whether he has stated the difference correctly or not, is immaterial to this point.

The principle of Self-love has also been well illustrated by Aristotle in its relation to Virtue. He distinguishes between the culpable form of it, or selfishness, and that form of it which is auxiliary to virtue. Self-love, then, in its good sense, may be acted on by the virtuous man, whose character is already framed on the principle of "the honourable;" and in that case, he shews, it will be coincident with Benevolence; since the person so pursuing his own interest will also effectually promote that of others. But this is not the case with the bad man; since, in pursuit of his views of self-interest, the bad man will at once injure himself and others by compliance with bad passions.[6] It is further evident from the above, that he does not admit of Benevolence being made a principle of conduct, otherwise than as it presupposes other moral principles, and is regulated consequently in its exercise by a prevailing regard to the "honourable" or right. He has also enforced his primary notions of Duty by pointing out the proper amiableness of virtue, both as the only sure tie of attachment between man and man,[7] and as the only thing which produces tranquillity, self-satisfaction, and delight, in a man's own bosom. On the latter point, indeed, he speaks almost in terms descriptive of the joys and pangs of Conscience.[8] So justly has he embraced in his view the most powerful auxiliary principles, without exalting them,

[1] *Eth. Nic.* i. c. 13, iii. c. 12; *Polit.* viii. c. 14.

[2] *Eth. Nic.* x. c. 9.

[3] *Eudem.* iii. cap. 7; *Eth. Nic.* ii. cap. 6, ὁ μητε πλεοναζει, μητε ελλειπει, του δεοντος—στοχαστικη γε ουσα του μεσου.

[4] A moral philosophy of this kind is in fact a revival in a new form of the theory of Socrates, which made virtue a science. It overlooks the affections in the production of virtue, as the theory of Socrates did.

Practical Philosophy.

as some philosophers have done, to an undue place, by making the Theory of Virtue to rest on them.

Such, then, is that account of Virtue which Aristotle's Practical Philosophy develops. He delivers it as the theory of perfect conduct—as that, which is exemplified in operation whenever human good is realized in life. It is at the same time, it should be observed, both an account of the Nature of Virtue, and of the internal process of Man's Constitution by which Virtue is produced. The affections being all habitually moderated by Prudence, Virtue is the result; and in that Moderation consists the Nature of Virtue.

He was not, however, inattentive to the fact, that the speculative perfection of a practical rule is not realized in Human Life. He was aware that a complete subordination of the Affections to the principle of Prudence was a task of difficulty above the efforts of Man as he is. So also his view of Vice, as that state of man in which his principles are entirely corrupted,[1]—the affections being conformed to evil, so that he continually and insensibly[2] chooses evil rather than good,[3]—is a philosophical limit of the extent of human depravity, and not an account of Vice as it actually exists in the world.[4] It is indeed a just conclusion, from experience of that degradation to which our nature is brought—the hardening of the heart, as the Scripture terms it, by the habitual violation of duty. As the end, therefore,—as the perfect form of vice,—this state of the heart demands to be sketched out by the moralist, to give the full truth and cogency to his admonitions. His outlines of virtue must be drawn from Virtue realized in its tendency—from that condition of it in which it is the attainment of man's Chief Good; as Vice, on the other hand, must be contemplated where it stands fully confessed as man's Chief Evil. There may be a virtue above Man's nature, as there may be a vice below it; and Aristotle notices both these extremes. But neither of these presents a standard of human excellence or human depravity, and therefore requires no distinct consideration in an Ethical treatise. The actual virtues, however, and vices of men, as they are observed in the world, exhibit an endless variety of modifications within the theoretic limits of Virtue and Vice. The Affections are more or less brought into subjection to the rational principle in different individuals; and men are praised and blamed in proportion as they have established this command over themselves, or have impaired and lost it. Hence a secondary or inferior kind of virtue results, as well as a less odious vice. As it is in the indulgence of the sensual affections that human frailty is most seen, Aristotle distinguishes this secondary virtue and vice by contrast with the particular virtue and vice of Temperance and Intemperance; as if they were simply what we express by Continence and Incontinence. But his distinction of their nature is a general one, and belongs to the whole character of Virtue and Vice.[5] But in admitting a morality of this nature, he laboured under a speculative difficulty. Socrates had denied the existence of any such imperfect vice, on the ground, that the virtues were sciences; and that it was impossible for a man to act against his knowledge of the best. Aristotle, who, though not agreeing with Socrates in regarding the virtues as sciences,[6] still admitted an intellectual process in the production of Virtue, felt himself required to explain how this higher principle was ever overpowered by the weaker, as it is in the incontinent man. In the course of this explanation, he has touched on the true philosophy of those facts in which the principles and practice of men are evidenced at variance. He has accounted in some measure for the apparent anomaly of the same person exhibiting such contrasts of character—at one time commanding the passions, at another yielding to them. For he delineates, it should be observed, under the characters of "the continent" and "incontinent," not two different persons, as in the case of "the temperate" and "intemperate," but what will usually be the same person at alternate intervals; since no one can very long remain either. For by the one course continued long, and the habit consequently formed, a person will become the "temperate" man, by the other the "intemperate."

The question of the freedom of the Will has been admirably treated by Aristotle. It is discussed as it ought to be in a treatise of Moral Philosophy, independently of those metaphysical difficulties with which it is commonly overlaid. What the nature of human Will is, whether free or necessary, according to our abstract notions of liberty or necessity, forms no part of his inquiry. He points out simply, what are the classes of actions in which an agent is generally held *not* responsible for his conduct; and excluding these, decides on the remainder—that, since in these, men *are* held responsible (as is shewn by the praise and blame, reward and punishment, attaching to their conduct), the actions are voluntary. This is the extent to which the inquiry, so far as it is strictly ethical, ought to be carried. Whether we speculatively conclude the Will of man to be free or necessary, *practically* we must regard it as free. For to act on that supposition accords with the facts of human life: whereas, to act on the theory that we are under a necessity, would lead us against the practice of mankind, which treats persons as responsible for their actions. Aristotle indeed argues, that though the question be decided in the negative, it leaves the relative nature of virtue and vice on the same footing. If their virtues may still be imputed to men, so may their vices.[7] But he more distinctly affirms the *voluntary* nature both of virtue and vice, on the ground that the αρχη, the principle of the action, is εφ' ἡμιν—in ourselves—in our own power. Thus, though the virtuous or vicious habits that men have formed may dispose them to a particular course of behaviour, so that, *as under their influence*, they cannot act otherwise, yet the actions so performed are voluntary; because it was in their power to pursue or forbear from that course of conduct which led to the settled habit, and to the corruption of their moral principles.

The principle thus described as "in ourselves," is, in Aristotle's Philosophy, the Motive of action. It is that from which the *effect* in the conduct originates; and it comes, therefore, under that class of principles, which constitute the Motive or Efficient Cause. The term, Motive, however, is popularly applied to the *object* or *end* of an Action,[8] which being something external to ourselves, or at least capable of being so viewed, gives occasion to question the voluntary nature of Actions. An aim, indeed, at a particular end is

[1] *Eth. Nic.* vii. cap. 8, Ἡ γαρ αρετη και μοχθηρια την αρχην, ἡ μεν φθειρει, ἡ δε σωζει; vi. 5, Εστι γαρ ἡ κακια φθαρτικη αρχης.

[2] *Ibid.* vii. cap. 9, ἡ μεν γαρ κακια λανθανει. *Rhet.* ii. 4, τα δε μαλιστα κακα, ἡκιστα, αισθητα, αδικια και αφροσυνη. This insensibility is the result of confirmed habit; and the same result takes place in regard to virtue. The moral principles are less felt, as mere internal principles, when perfected in the character; operating as it were without thought or effort, in the conduct. See Bishop Butler's *Analogy*, chapter on Moral Discipline.

[3] *Ibid.* vii. cap. 8, Ὁτι μεν ουν κακια ἡ ακρασια ουκ εστι, φανερον· αλλα πη ισως· το μεν γαρ παρα προαιρεσιν, το δε κατα προαιρεσιν εστιν.

[4] *Ibid.* iv. cap. 5, Ου μην ἁπαντα γε τῳ αυτῳ ὑπαρχει· ου γαρ αν δυναιτο ειναι· το γαρ κακον και αὑτο απολλυσι, καν ὁλοκληρον ᾐ, αφορητον γινεται.

[5] *Ibid.* vii. c. 7; *Eudem.* vi.; *Eudem.* iii. c. 11.

[6] *Eudem.* vii. c. 13; *Eth. Nic.* vii. c. 3.

[7] *Ibid.* iii. c. 1, 5; which is in substance the conclusion of Bishop Butler (*Anal.* p. 1. chap. on the *Opinion of Necessity*). The whole doctrine of this chapter is coincident with the views of Aristotle, and illustrative of them.

[8] Paley speaks of "private happiness" as "a motive." (*Mor. and Pol. Phil.* b. ii. c. 3.) We use the term correctly when we say that ambition or avarice is a person's motive, but not in saying that power, or interest, or happiness, is so; for these are ends.

Practical Philosophy.

implied in every Action; and on the End sought depends the morality or immorality of the Action. But, in strictness, it is the Choice alone that moves the agent.[1]

But the principles employed in the production of Moral virtue are not the whole of our internal nature, nor are they the highest principles. And Aristotle's theory implies the exertion of all; and further, if there be a relative superiority among them, a preference of the higher. The moral virtues, according to the theory of Plato which he adopted, having their seat in that part of the soul which was termed irrational, —or only rational as it was capable of obedience to Reason, —were the virtues of the inferior part. Accordingly, the greatest Happiness must result from the exertion of the Intellectual principles. Analyzing these into the five heads of, 1. Science, or the knowledge of Demonstrative Necessary Truth; 2. Art, or the knowledge of Contingent Truth in the operations of man; 3. Prudence, or the knowledge of Contingent Truth in the conduct of Life; 4. Intelligence, or the knowledge of First Principles; 5. Wisdom or Philosophy; he assigns the pre-eminence to the last, as the perfect combination of Science and Intelligence, and as having for its objects the highest natures.

That a philosopher, living amidst the disorder and misery occasioned by the want of true Religion, should have sought for a perfection of happiness out of the troubled scene in which moral virtue is disciplined, cannot excite our wonder. The calm regions of philosophical contemplation —*sapientum templa serena*—presented a natural refuge to the anxious mind, eager to realize its own abstractions in some perfect form of human life. It was a search, indeed, after that happiness which Revelation has made known to man—a happiness out of his present sphere of exertion and duty, where he might obtain the full end, or consummate good, of his being. Aristotle accordingly describes the pursuit of *this* ulterior happiness, as the "immortalizing" of our nature; as the living according to what is divine in man; as what renders a man most dear to the Divinity, most godlike.[2] Not attributing, however, any real immortality to the nature of man, he could only draw his notion of perfect happiness from a view of the present life.[3] In this view, the Intellectual virtues are undoubtedly entitled to the preference; though experience must have convinced him, that even these are not without their alloy.[4] He by no means, however, regards the exercise of the Intellectual virtues as an exemption from the necessity of cultivating the Moral. The happiness of the Theoretic life is the highest privilege of man's nature. Still the practice of the Moral virtues is enjoined, that each person may perform his part as a man living amongst men. No philosophy but that of Aristotle has so justly maintained this proposition. Plato would lead his followers into the indolent reveries of mysticism; the Stoics would reduce theirs to indifference about human things; the Epicureans would absorb theirs in the fulness of present delights; Cicero would degrade the higher functions of the contemplative life below the ordinary moral duties, confounding the dignity and the indispensableness of an employment. But Aristotle elevates the aim of man to that happiness which, as purely intellectual, is inadequate to the wants of a nature consisting of body and soul; whilst he calls him also to the strenuous discharge of the duties belonging to that compound nature, and to his actual condition in the world.

Politics.

The experienced inefficiency of ethical precepts in themselves to produce morality in the lives of men, and the consequent appeal to some external sanction for their enforcement, led to such works among the ancients as the Politics of Aristotle. The Christian observes the same fact, and draws from it a strong argument for the necessity of a Divine Revelation. Aristotle and other Greek philosophers looked to the influence of Education directed by civil laws and institutions, and to the rewards and punishments of civil government, as the great instruments for bringing mankind to that course of action in which their real interest consisted.

In ascribing this moral force to the law of the state, Aristotle adopted the current notion of Ancient Philosophy, which confounded moral and political good. The good of man as an individual was conceived perfectly coincident with his good as a citizen; and the science of Politics, therefore, was treated as including under it that of Ethics. Had not philosophers been misled by their extreme pursuit of abstract speculation, they could hardly have thus blended together the distinct objects of moral and political science in one common theory. They would have seen that the social union could only indirectly promote that good of man which belongs to his internal nature; that it could reach no further than to the protection of the individual from external aggression on his person and property, and allowing him the unobstructed exercise of his virtue. "Civil government," says Bishop Butler, "can by no means take cognizance of every work which is good or evil; many things are done in secret, the authors unknown to it, and often the things themselves; then it cannot so much consider actions under the view of their being *morally* good or evil, as under the view of their being mischievous or beneficial to society; nor can it in any wise execute *judgment* in rewarding what is *good*, as it can, and ought, and does, in punishing what is *evil*."

In consequence of this misapprehension of the end of the social union, the Political philosophy of Greece was not a system of jurisprudence, nor any discussion of questions affecting the policy of particular states. It was a speculation concerning the Perfect Polity—a theory of social happiness considered as the result of positive institutions and laws. Ingenious men amused themselves with fancying how society might be modelled, so as to exhibit an ideal optimism; instead of attending to the real phenomena of human life, and deducing from them the right administration of Society under its existing forms.[5]

Aristotle, accordingly, constructed a theory of Politics on this delusive principle. Proposing to himself the Perfect Polity, as that in which the virtue and happiness of the man and the citizen exactly coincide, he proceeds to sketch out the form of it, and thus to obtain an outline of the institutions on which his ethical system must depend for its support. But he was not so fascinated by the theory on which he worked, as to overlook the practical nature of the science. He complains of his predecessors, that however well they might have treated the subject in other respects, they had at least failed in the useful. They had contented themselves with devising forms of polity which could only be realized with a concurrence of every favourable circumstance: whereas the usefulness of the science required the delivery of principles such as were practicable in existing cases. We know, indeed, from the titles of other works on Politics which he is said to have written, *The Polities of One Hundred and Fifty-eight States*, four books *On Laws*, and two books *On the Political Man*,[6] that he did not consider the subject as exhausted in the theory of a perfect polity. The observations, too, on Justice and on Civil

[5] Draco, however, and Pittacus, were only framers of laws, and not of polities. (Aristot. *Polit.* ii. c. *ult.*)

[6] These works are mentioned by Diogenes Laertius. A portion of the *Polities of One Hundred and Fifty-eight States*, relating to the constitution of Athens, has been preserved by Julius Pollux.

Practical Philosophy.

Policy, contained in his Ethics and Rhetoric, are proofs of the sound practical views with which he contemplated the subject. And even in the work now before us, which develops his professed theory of Politics, the substance of the inquiry is, judicious and enlightened instructions of policy, drawn from experience of human nature, and applicable to all times and circumstances. From its connection with his Ethics, it was intended, probably, to be applied by each individual in the practical business of Education. He wished the student to obtain that scientific knowledge of the effects of institution and discipline on the human character, which might assist him in the treatment of the particular cases of his own experience.[1] It thus harmonized completely with his Ethics; the object of which was, as has been shewn, to enable each man to attain his own particular good by a general knowledge of the real good of man.

The perfect polity sketched by Aristotle is a theory of the end to which man, viewed in his social capacity, at its best estate, and unimpeded by external obstacles, may be conceived to tend. It is a view of the End or τελος in his Political system, corresponding to his account of the Chief Good in his Ethics. He arrives at it by the same train of thought which led him to his account of the Chief Good. He considers, first, that man, independently of any calculations of expediency, is naturally a political being;[2] as in his Ethics he assumes that man is endued by nature with active principles tending to his own good. He admits that Expediency is instrumental in cementing the union among men, but does not rest society on this principle; wisely judging that man is induced originally to associate with man by various internal principles of his nature, and not simply by motives derived from reflection on his wants. Such motives are in truth only secondary causes, and auxiliary to the former; in like manner as the principle of self-love is auxiliary to the natural affections on which virtue is founded. As, then, in his Ethics, he went on to inquire what principle rendered actions perfect, exhibiting them as attaining the end for which Nature had constituted the Affections; and as this principle formed the Chief Good of his Ethical system; so in his Politics, he carries on his view of the social nature of man to the point where the union to which it tends appears self-sufficient and perfect. The mode in which the social principles might be found to operate in this ultimate case would present the perfection of Social Virtue. And from this specimen of Social Virtue would be deducible right forms of government, institutions, and laws, just as the rules of right moral conduct are drawn from the whole moral nature of man contemplated in its perfection.

To put ourselves, accordingly, into that posture of mind in which Aristotle contemplated the subject, we must suppose the case of a Society analogous to that of an individual. The analogy between the principles of the heart, as a constitution, or system of related principles tending to a common end, and the elements of a political community, could not but be familiar to the mind of a disciple of Plato, who delighted in drawing his outlines of moral virtue from the imagery of social life. But Aristotle, though sometimes imitating the beautiful language of Plato in his ethical descriptions, has inverted the analogy, and framed his representation of a perfect society after the resemblance of the internal constitution of the heart. We must imagine, then, the various members of a community, when brought to the standard of perfection implied in the notion of a Perfect Constitution, all obtaining their respective dues, in a manner analogous to the due moderation of the affections in the virtuous character. A "mean" is to be attained in the one case as in the other.

Agreeably to this view of his mode of speculation on the subject, he describes the Perfect Polity as a mixture of Oligarchy and Democracy—as a state which appears to be both these forms of government, and yet neither of them; in which, no one of the component elements of Society has preponderance, but the claims of freedom, of wealth, and of virtue,[3] are all duly considered. A form of government which is thus a "mean" throughout, he designates by the name of "Polity" or commonwealth; appropriating to it the general name, and thus distinguishing it as the perfect form, the proper constitution of a πολις, a City or State;—a city or state being the "end" of the Social union.

If, indeed, the promotion of virtue, were the direct and proper object of the Social union, as Aristotle conceives, it must be allowed, that that only can be a perfect constitution of Society, in which the standard of political rights is the same with that of moral right. In this ultimate perfect form, upon such a supposition, the science of Politics becomes absorbed in that of Ethics. The community in this case acts as the dispenser of the laws of morality; and its honours and its penalties are but the channels through which virtue works its own rewards of happiness, and vice its own punishments of misery.[4] But this is, as was before observed, to intrude on a province far beyond that of political science. Schemes for the moral perfection of Society belong to the wisdom of a Providence more than human, working good out of evil, and, from a boundless survey of all the relations of things, accomplishing important results by means apparently incompetent or even adverse. Man, in his designs of moral good, has only to attend closely to the mechanism placed under his observation—to use the appointed means—to cultivate given powers—to provide against foreseen consequences;—and then, having done his part, to trust that the happiness, which must surely be the end of the whole under a wise and good Providence, will be the final result of his well-ordered exertions. Thus, it is manifest to our view, that from the ungoverned passions of men evil will ensue. Society, therefore, may lawfully be employed as an instrument for preventing this misery, so far as external means can reach it; and so far, too, it may encourage virtue, and indirectly promote human happiness.[5] But let it propose to itself "what is best" as the distinct aim of its constitution; and it bewilders itself with theories, no one of which will probably realize the expectations conceived of it; whilst, on the contrary, some evil must certainly ensue from artificial attempts on so large a scale. For it is impossible, as Aristotle himself observes, but that, "from false good in the outset, real evil must at length result."[6] He is quite consistent here, however, with the rest of his philosophy. Excluding from the course of nature a Providence distinct from Nature itself, he proceeded, according to his system, to attribute an internal self-adjusting power to Society considered as a work of Nature. The maxim, that "Nature does nothing in vain," is at the base of his moral and political philosophy, as well as of his physical. The perfect polity is an illustration of this maxim. It is the perfecting of the self-provisions of Nature in man considered as a social being.

The real excellence, however, of Aristotle's theory of the Perfect Polity consists in this; that if we admit a Divine Providence, to whose foresight we ascribe the final cause or ultimate tendency of the social union, it is a negative description of the policy which should be pursued in every well-

[1] *Eth. Nic.* x. c. *ult.*

[2] *Polit.* i. 2, iii. 6.

[3] Nobility, according to Aristotle, is "ancient wealth and virtue;" or "the virtue and wealth of ancestors;" and does not, in his view, therefore, form a distinct head of claims. According to Laertius, he wrote an express treatise, Περι Ευγενειας, in one book.

[4] Bishop Butler's picture of a perfectly virtuous kingdom will readily occur here. (*Analogy*, part i. chap. 3.)

[5] *Polit.* i. cap 2, φυσει μεν ουν ἡ ὁρμη, κ. τ. λ.

[6] *Polit.* iv. cap. 12, v. cap. 1.

constituted state. It points out the manner in which the public welfare must be sought; that is, by not making any one of the objects commonly pursued in the political world the sole or chief object of pursuit to the community. On the hypothesis, that the happiness of the world is the care of Him who ordered it, every society should be so constituted as that no appointment of Providence be overlooked, but every part of the social machinery be brought into action. The love of conquest, for instance, will not be the aim of such a state. Such a policy would employ its military resources only, to the exclusion of its other materials of happiness. Aristotle particularly points out this in the instance of Lacedemon, whose whole policy was framed for war; whereas, as he observes, a state should be adapted for living well in peace, and enjoying that repose which is the end of its engaging in war.[1] Nor, again, will the mere accumulation of wealth be the express aim of the state in its whole policy. Such a ruling principle would tend to degrade the great mass of the population, and to undo the very connection itself between the members of the community, by pushing the boundaries between the rich and poor to the extremes of opulence and pauperism; of which condition of things the natural result is, the tyranny of an Oligarchy. Lastly, if even liberty is made the exclusive aim of state policy, unhappiness is the sure result. Whilst the members of the community grasp at an unrestrained liberty, they disregard the various gradations of society, by which the sphere of human duties is enlarged, and the greatest securities against violations of liberty are provided; and thus a wild Democracy usurps the place of a just Polity. Now, Aristotle's theory excludes all such gross schemes of policy. It admits only the general pursuit of the public welfare; which, like the private happiness sketched in his Ethics, is not to be made a *distinct* object under any particular form, but must be the *general* pursuit of the *whole* organization of the society; as private happiness is the *result* of the *general* regulation of all the moral principles. It is true, that he supposes a society to constitute itself in order to its own moral perfection and happiness; and herein is the error of his theory. But this notion being a substitute in his system for a Divine Providence, it did not imply that the individual members of the community should propose to themselves, as their direct object of pursuit in life, that happiness to which the social system, as a whole, should tend. It was to be brought about by that mysterious agency which, from not admitting a real Providence, he was compelled to ascribe to Nature.

This is further illustrated in his description of the three right forms of government, and the three improper or deviations from the former. He admits that the public welfare may be promoted under other forms—under a Monarchy or an Aristocracy, as well as under "the Polity" or commonwealth. These three forms are indeed coincident in principle, according to him; being variations produced by differences in the character of the people among whom they arise.[2] The perfect "Polity" presupposes an equality among the members of the society,—that all are capable in turn of governing, as well as of being governed. But there may in some cases be marked differences between a family, or an individual, or a class of individuals, and the bulk of the people; and in these cases the rule of justice requires that there should exist in the former a monarchy, in the latter an aristocracy. So far, indeed, does Aristotle carry this principle as to say, that any single person eminent in worth above the rest of the community, as one of a more divine nature, ought to have entire obedience from the rest, and to be perpetual Sovereign.[3] The three forms, then, of Monarchy, Aristocracy, and Commonwealth, are right; because, being founded on the relative merit of the members of each society, and the standard of merit being virtue, the rule of justice is maintained in them. The public good follows, therefore, not from the ascendancy of this or that principle in the government in each case, but from a due regard to all subsisting relations in the state. But in the corresponding perversions of these right governments—in a Tyranny an Oligarchy, and a Democracy—particular principles prevail, and particular interests, accordingly, are consulted, to the violation of justice and the sacrifice of public good.

Aristotle appears the only political theorist among the ancients who never lost sight of the moral nature of man in his speculations. The systems of other theorists, as Plato, Phaleas of Chalcedon, Hippodamus of Miletus, and the constitutions of Lacedemon, Crete, and Carthage, for the most part treated Human Society merely as a physical mass, capable of being moulded into particular forms by the mechanism of external circumstances. Aristotle, on the contrary, lays the chief stress on the force of "customs, philosophy, and laws,"[4] for producing the best condition of society. Still as, in his Ethics, in order to the development of his theory of the Chief Good of man, he supposes a condition of human life adequate to the exercise of the moral powers; so, in his Politics, he supposes a concurrence of circumstances favourable to the existence of the perfect Polity.[5] In this theory as in that, there must be no impediment from without to the operation of the principles. Here, as in the Ethics, the production of the desired effect is the combination of three principles—Nature, Habit, Reason.[6] Therefore, also, as there must be certain elements of virtue in the heart in order to the moral improvement of an individual, so there must be the proper elements of the perfect social life in the community where the perfect commonwealth is to be reared. Then, upon these natural principles of the head and heart, a course of public Education is to proceed, disciplining the members by habit and by reason to the perfection of the social character, in a manner analogous to the discipline by the individual of his own character.

We find the same fundamental agreement with the moral system of the Ethics, in the method of Education proposed by Aristotle for the citizens of the perfect Polity. The maturity of the intellectual powers is here also to be the end to which the system tends. The members of the community are to be trained so as to be capable of enjoying the leisure and repose of a peaceful state. This they are to regard as their ultimate proper sphere of happiness; whilst at the same time they are disciplined to the virtues of that active life, by which alone the permanence of their tranquillity can be secured. It is obvious how this harmonizes with the doctrine of the Ethics, which sets forth the happiness of the Theoretic life as the highest bliss of man's nature, but not independently of the practical duties of common life. For thus he directs the course of training through which the young must pass, to commence with the body; then to proceed to the disposition of the heart, and to end with the intellect; the inferior principles being disciplined in subordination to, and with reference to the higher. Even the sports of childhood were not neglected by him in the scale of Education. He would further provide for the best bodily constitution of the citizen, by regulating the period of marriages with a view to a healthy offspring, and the care of the mothers during pregnancy. Here, indeed, we are shocked at finding in such an author a sanction to infanticide and abortion. The law, he says, should forbid the nurturing of the maimed;[7] and where a

check to population is required, abortion should be produced before the quickening of the infant; no law of morality he thinks, forbidding it at this period.[1] These are striking instances of the infirmity of a philosophy, which substitutes an intrinsic agency in Nature for the counsels of an intelligent Divine Agent working on Nature. According to such a philosophy, everything adverse to the perfection of Nature is a stumbling-block. On the hypothesis of a Providence, the good and the evil may be contemplated with equal assurance that "the best" will in the end prevail. In the former case human reason removes, suppresses, destroys; in the latter it moderates, counteracts, overrules; doing nothing with rash violence, but gently conspiring with the appointed course of things, in opening a way for good out of the evil. In Aristotle, the immoralities here noticed are, moreover, at direct variance with the precepts and spirit of his Moral philosophy.

Again, the same moral complexion characterizes both the public and private discipline of the philosopher. The honourable, *το καλον*, predominates over both. By this standard every institution, whether of bodily or mental exercise, is to be regulated. No illiberal arts, such as required manual rather than intellectual skill, are to be taught. Not even are the liberal sciences to be pursued excessively, or with exclusive devotion to any particular ones, or with mercenary views; the occupation of leisure being the end proposed by the system of education. What was useful or necessary was to be learned, but in subserviency to the honourable; and the honourable rather than the useful or necessary.[2] Hence the stress laid by Aristotle on the arts of Painting and Music. It was, in the result, a general cultivation of the mind by literature combined with moral discipline, and not the storing it with particular sciences, which his system of Education contemplated. He saw that the tendency of particular studies was to contract the mental powers to that particular range of vision to which they were confined: whereas he sought rather to impart a largeness and masculine strength to the understanding, commensurate with the varied demands of the world in which human life is cast. It was what we should express by the education of the accomplished gentleman,—of one who, exempt from the drudgery of life, and having his actions freely at his own disposal, might be qualified for the highest functions to which nature has destined man in forming him a moral and social being. For it should be observed, that Aristotle throughout supposes an entire immunity from all servile employments, both to the happy man and the happy citizen.[3] According to his view, a large proportion of mankind are physically incapable, either of the happiness of moral beings, or of that of social life. Persons so imperfectly constituted he conceives to be wholly dependent on others, and to be by nature *relative* beings or slaves; their proper nature being comprised in this relationship of dependence.[4] To this class, accordingly, he would commit all the labours of agriculture, of the mechanical arts, and the market, and all menial offices: whilst others, more gifted by nature, enjoy leisure for the proper duties of man, in the various relations of a moral and social being.[5]

The justification of the condition of slavery is thus rested by Aristotle on abstract grounds. He viewed it as an institution of nature; differing in this from other philosophers, and from the popular notion of his own countrymen, who either founded it on the right of conquest, or on an assumed original difference between Greek and Barbarian. This was a far more liberal view of the subject than that which prevailed generally in his time. For it implied, that no one had a right to retain another as his slave who was not thus physically dependent. Every one had a right to be free, who was capable of enjoying freedom in the performance of the duties for which man in his perfection was constituted. This doctrine further imposed on the master a strict moral attention to his slave. The slave was thrown on him not only for support, but for direction in his duties.[6]

That Religion should have formed no part of the business of Education in his system, was further consistent with his Ethics. The Moral *καλον* terminated in the perfect fulfilment of all those relations in which man was placed as a being of this world. It was heightened by the consideration, that Gods might delight in looking down on such perfection, and that in its highest state it resembled the excellence of divinity. But it did not strike its roots into, or draw its nourishment from, Religion. Nor did the *καλον* of Social life. The accomplished citizen might be taught to contemplate himself in the thoughtful activity of a philosophical leisure, as holding a dignified station among men, analogous to the divine principles which maintain the order of the universe.[7] But there was no connection between his social virtues and his religious system. The religious colouring was only the borrowed light of Philosophy. All active Religion was consigned to the instrumentality of a particular body of men—the Priests. The obligatory force of Religion was recognised; but being lodged in an external establishment, as its depository and sanctuary, reverence was sought for it by outward bonds of respect, by the privileges of the order to whose care it was intrusted, and the splendour of its public spectacles. Aristotle, accordingly, treats the subject merely as one of policy. He observes, that no one of the rank of a mechanic or peasant should be appointed a Priest, since it was necessary that the gods should be honoured by the citizens; and he points out the importance of the religious character to the absolute sovereign of a state, in order to the obedience of the subject.[8]

Aristotle's account of his theoretic Polity leaves off abruptly at the end of the 8th book; and the treatise is thus, as now extant, an imperfect development of his views. But the theory of the Perfect Polity is only a part of the very valuable materials of the *Politics*. The work embraces a wide survey of the social nature of man. Throughout, indeed, it may be studied as elements of the philosophy of History. It lays open the principles of preservation and decay inherent in the different constitutions, and points out the common principles on which the maintenance of civil order, under any form whatever, must essentially depend.

Nor has the study which now obtains the name of Political Economy been overlooked by Aristotle. The nature of Money, and of the wealth to which it has given rise, particularly attracted his attention. It may suffice to shew how accurately he thought on the subject, to observe that his account of the origin of Money,—tracing it to its service, as a common measure of value in exchanges, and as a conventional substitute for a demand for commodities,—has been adopted by the author of the celebrated work, *The Wealth of Nations*.[9]

On the whole, justly to appreciate the labours of Aristotle in Political Science, we should compare them with the elaborate and eloquent works of Plato on the same subject—the

Practical Philosophy.

Dialogues entitled *The Republic* and *The Laws*, and especially *The Republic*. Aristotle evidently had this work before him in the composition of his own, and in several places has made express allusions to it. His two treatises of the *Nicomachean Ethics* and the *Politics*, convey incidentally a refutation of the errors in moral and political philosophy contained in Plato's speculations. It is but a small portion of Plato's *Republic* which belongs to Politics; the bulk of it being devoted to moral and metaphysical discussions. Aristotle's more exact philosophy discriminates the subjects strangely though beautifully blended in that episodic work. He has taken much of what is excellent in the treatises of Plato into his own; but at the same time has the merit of originality, in the correction and enlargment, as well as systematic arrangement, of the principles there diffusely delivered. He acknowledges, referring to the *Dialogues* of Plato, that all the discourses of Socrates have in them "the admirable, and the exquisite, and the inventive, and the searching;" whilst he claims a right to discuss them, on the ground, that "for everything in them to be right was perhaps difficult."[1]

Plato's theory was metaphysical throughout. That oneness which he sought to establish in his perfect Republic was an abstract unity, the realizing of which constituted, in his view, the best Polity; as the realizing of the one self-existent "idea" of good constituted the morality of actions. Thus, his Magistrates are philosophers, and his Virtue is wisdom. A character, on the other hand, decidedly practical, pervades the moral and political disquisitions of Aristotle. They are immediately adapted to the actual needs of man. They have not, on this very account, that peculiar charm which belongs to Plato's writings. The imaginative perfection shadowed out by Plato, imparts an interest even to his subtile disputations, and engages the feelings of the reader, amidst the reluctance of his judgment. And thus his works tend to a practical effect, in opposition to their speculative character. But Aristotle, throughout intent on the business of human life, forbears to seize the imagination with romantic pictures of excellence, either in man individually, or in society. He points out such happiness as is attainable, or at least to which human endeavours may reasonably be directed, in that condition of the world in which man has been placed. His discussions on moral subjects are accurate observations, and powerful reasonings, applied to things as they are. But this character renders them of more general use than Plato's speculations. The man of genius and of sensibility might feel a stronger stimulant to moral and social energies from the study of the animated pages of the *Republic*. But the generality of mankind would undoubtedly obtain a more ready help in the duties of life, from the practical principles of conduct delivered in the less ambitious philosophy of Aristotle.

CONCLUSION.

Design of Aristotle's Philosophy—Style of his Writings—His Obscurity—Method of Discussion—Originality.

From the review which has been taken of the extant writings of Aristotle, it would appear that the great object of the philosopher was to discipline the mind by a deep and extensive course of literature. The various inquiries embraced in those writings,—the unwearied research into subjects the most repulsive from their abstruseness, or the most interesting from their connection with the feelings and actions of men,—the richness of illustration from the volumes of ancient genius, and from observations of mankind with which they abound, are so many proofs of the noble object proposed in his philosophy. It may be fully concluded that it was not the mere sophist of former days, or the disputant on any given question, that Aristotle aimed to accomplish. His object was, like that of Socrates, to render man really wise, by a cultivation of all the moral and intellectual powers of the soul; in order that the great moral of the whole—the good towards which Nature tends—might be realized in each individual so instructed and disciplined. Agreeably to this view is the answer attributed to him, when, on being asked what advantage had accrued to him from philosophy, he replied "To do without constraint what some do through the fear of the laws."[2]

Some of his works appear to have been written in the form of Dialogue. These were probably of the class called Exoteric; that form being more adapted to the purpose of explanation and fuller discussion,—which seem to have been characteristics of the Exoteric treatises,—in contrast with the concise and suggestive form of the Esoteric or Acroamatic. Among his works are also mentioned *Epistles* to Philip, to Alexander, Olympias, Hephæstion, Antipater, Mentor, Ariston, Themistagoras, Philoxenus; besides a collection entitled *Epistles of the Selymbrians*. A hymn in praise of the virtues of his friend Hermias has been already noticed; which formed matter of accusation against him on the ground of impiety. It has been preserved by Diogenes Laertius. It consists of twenty-three lyric verses, celebrating Hermias among the heroes who had sacrificed their lives for the cause of virtue. Laertius has also preserved four lines inscribed by him on the statue of Hermias erected at Delphi. His poetical talent was further displayed in verses addressed to Democritus, and in the composition of an elegy; of both which poems the first lines are given by Laertius. The titles of various other works, or parts of works, occur in the catalogue of his writings. So laborious, and so diversified, were the literary pursuits of this great philosopher. These were works, too, written, we must remember, not by a sequestered individual, enjoying the privacy of a privileged leisure like the Priests of Egypt, but amidst the agitation and troubles of Grecian politics, or in the courts of princes. We may well, therefore, wonder at the abstractedness of mind, the single-hearted zeal of philosophy, which thus steadily pursued its course, creating its own leisure, and keeping the stillness of its own thoughts. Probably, indeed, such writings could hardly have been produced, except with a concurrence of such opposite circumstances. They imply at once the man of the world and the retired student,—ample opportunities for the contemplation of human nature in the various relations of life, familiarity with the thoughts of others by reading and conversation, as well as intense private meditation, that communing with a man's own heart, which alone can extort the deep secrets of moral and metaphysical truth.

The style of his writings bears the impress of his devotion to the real business of philosophy. The excellence of his style is, we believe, the last thing to attract the notice of his readers; and yet, as a specimen of pure Greek, it is found to stand almost unrivalled. The words are selected from the common idiom; but they are employed with the utmost propriety; and by their collocation are made further subservient to the perspicuity and force of his meaning. There is nothing superfluous, nothing intrusive, in his expressions; but the very ornaments add to the terseness of the style. The metaphors and illustrations employed are apt and striking analogies, availing as arguments, whilst by their simplicity they familiarize the truth to the mind. That these excellencies should escape the notice of the reader engaged

Practical Philosophy.

in the matter itself of the author, is a proof of the strict adaptation of the style to the matter. We can imagine, that to the Greek reader nothing could have been easier than to apprehend the meaning of the philosopher. To the modern, the necessity of studying the language gives an apparent hardness to expressions, whose propriety depends on an accurate perception of the genius of the language. Thus, what was a facility to the ancient reader is a difficulty to the modern, until the latter, by study of the language, has brought himself as much as possible into the situation of the former. This observation will be illustrated by a comparison of the style of Plato with that of Aristotle. Plato's style, undulating with copiousness of diction, is more attractive to the modern reader; his meaning is often more readily apprehended at the first glance, by the number of expressions which he crowds on a point, and their accumulated force of explanation. But in Aristotle, if we miss the force of a term or a particle,[1] or overlook the collocation of the words, we shall sometimes entirely pervert his meaning.

There are, however, passages in which Aristotle departs from his usual conciseness, and approaches towards the eloquence of Plato. The concluding chapters of his *Nicomachean Ethics* may here be particularly pointed out; or a part of the ninth book of that treatise, in which, evidently imitating Plato, he compares the tumult of uncontrolled passions to the disturbance of civil sedition. There is a dignity and a pathos in these passages, controlled by the general character of severe precision belonging to his style, yet admirably harmonizing with it. Sometimes, indeed, his style is chargeable with too strict a conciseness, as well as, on the other hand, with prolixity. These opposite faults are in him the same in principle; resulting from the pursuit of extreme accuracy;—an error in composition, compared by himself to that illiberality, which consists in too close an attention to minute matters in contracts.[2]

Nor can it be denied that there is considerable obscurity in the writings of Aristotle. It is important, however, to distinguish this obscurity from that of mere style. It is an effect of the peculiar design with which he appears to have composed them. Some are evidently outlines for the direction of the philosopher himself and his disciples in their disputations—notices of points of inquiry rather than full discussions of the subjects. This is very observable in the *Metaphysics*, the *Nicomachean Ethics*, and the *Rhetoric*. Sometimes he contents himself with a reference to his exoteric discussions.[3] It is probable that the most important works of his philosophy were not published in his lifetime; and that they thus constantly remained by him to receive improvements which further observation might suggest. This may partly account for some abruptness in those treatises. In our progress through them, we come to discussions which we had not been led to expect by anything previous in the work. The seventh book of the *Ethics*, for instance, appears to have been an afterthought; and so also the eighth and ninth of the same treatise. The work might have been regarded as complete in itself without them. In the *Metaphysics*, indeed, we can hardly judge what was the exact arrangement of the work; since it has descended to us in an imperfect, irregular form. But there are like marks in it of successive additions from the author.[4] The fact that the writings of Aristotle were left to Theophrastus, and not to his own relatives, would further imply, that they were intended primarily for those who had been trained in his school, and by whom his philosophy would be rightly transmitted. The immediate occasion of this reserved mode of writing may have been the jealousy of rival philosophers,[5] or the dread of pagan intolerance.

His method of discussion is conformable with the principles proposed in his Dialectical treatises. It is throughout a sifting of the opinions and questions belonging to the subject of inquiry, by examining each in its several points of view, and shewing the consequences involved in it. Accordingly, generally, before fully stating his own conclusions, he considers what may be urged on both sides of the question, putting the objections strongly and fairly, and giving the most candid construction to the views of his predecessors.[6] The difficulties proposed he sometimes briefly removes in passing on, having just glanced at them; at other times he devotes several sentences to their explanation. This, which is his method in parts of his system, is only a specimen of what is the collective result of the whole. His philosophy, dialectically viewed, is an analysis of the theories proposed by the philosophers who had preceded him. Consistently with this, he commences sometimes with observations on logical grounds,[7] or those views of a thing implied in the classifications which language expresses; and afterwards inquires into the subject physically or philosophically; when the discussion proceeds on principles of physics or philosophy in general.

With respect to the originality of his writings, there can be no doubt that he derived important aid from the labours of his predecessors, and especially from those of Plato. An accurate examination of his writings will convince the reader, that they are the productions of one who had deeply drunk of the fountain of Plato's inspiration. But they shew at the same time such a disciple as we may suppose the spirit of Plato would have delighted in; one who cherished the authority of the preceptor, and yet had the courage to love the truth still more;[8] one who thought it necessary to consult what others had said wisely and truly before him, and yet would examine a question finally with an independent discriminative judgment.[9] Estimating his philosophy thus, we may pronounce it to be truly his own. It was the fruit of his own sagacious, penetrating mind. A sufficient proof of this is his disagreement with Plato on the theory of Ideas,—the Origin of the universe,—and the Immortality of the soul. He has been charged, indeed, with invidious opposition to Plato, with corruption and misrepresentation of the tenets of his predecessors. Jewish writers have even absurdly accused him of plagiarism from the books of Solomon.[10] But there is no real foundation for these charges; they are at best but surmises; and they are fully contradicted by the internal evidence of the writings themselves. (R. D. H.)

---

[1] It is probable that the number of his distinct works has been made to appear larger than it really is, by the circumstance of parts of those now extant being described by the titles of the particular subjects to which they refer, and thus represented as separate treatises.

[2] *Metaph.* ii. 3. [3] *Eth. Nic.* i. c. ult., λεγεται δε περι αυτης και εν τοις εξωτερικοις λογοις αρκουντως ενια, και χρηστεον αυτοις. *Ibid.* vi. 4, πιστευομεν δε και περι αυτων και τοις εξωτερικοις λογοις. *De Cœlo*, i. 9, καθαπερ εν τοις εγκυκλιοις φιλοσοφημασι. *Eudem.* i. 8.

[4] Niebuhr (*History of Rome*, trans. p. 16) remarks this particularly of the *Rhetoric*.

[5] Valerius Maximus, viii. 14, reprehends Aristotle's sensitiveness on this point, mentioning his annoyance at the authorship of his *Rhetoric* being imputed to Theodectes, to whom he had presented the work for publication, and his care to assert his right to the treatise in a subsequent work. [6] *Metaph.* iii. 1; *Topic.* i. 2; *Cœlo*, ii. 13, &c.

[7] *Ibid.* vii. 4; *Polit.* vii. 5. Occasionally he illustrates from etymology, as in deducing ηθος from εθος (*Eth. Nic.* ii. 1), σωφροσυνη from σωζειν φρονησιν (*Eth. Nic.* vi. 5). "It is a practice with us all," he observes (*Cœlo*, ii. 13, p. 467), "to pursue an inquiry, not as it belongs to the thing, but relatively to an opponent in argument."

[8] *Eth. Nic.* i. 6, αμφοιν γαρ οντοιν φιλοιν, ὁσιον προτιμαν την αληθειαν. This is also the sentiment of Plato, *Rep.* x. αλλ' ου προ γε της αληθειας τιμητεος ανηρ. [9] *De Cœlo*, i. 10, το γαρ ειρηνην καταδικαζεσθαι δοκειν, κ. τ. λ.; *Polit.* ii. 6; *Metaph.* xiv. 8, p. 1002, Du Val.

[10] Brucker, *Hist. Crit. Phil.* vol. i. p. 794. This was merely to excuse their own adoption of his philosophy, as Brucker observes.

ARISTOXENUS, a Peripatetic philosopher, and native of Tarentum. He studied under Lamprus, Xenophilus, and Aristotle; and, according to Suidas, was the author of 453 works on music, philosophy, and history. The only one of these that is now known is his *Elements of Harmonics*, in three books, of which Meibomius published an edition with Latin translation and notes in his *Antiquæ Musicæ Auctores*, Amsterdam, 1652. This is considered the best edition of Aristoxenus's work, although it is imperfect; for part of each book is wanting, and great confusion occurs from transposition of passages. The Abate J. Morelli, librarian of St Mark's library at Venice, published fragments of Aristoxenus's *Elements of Rhythm* from a MS. in that library, Venice, 1785. By the term ἁρμονία, the ancient Greeks did not mean *harmony* in the modern sense of that word as applied to music, but the system of sounds upon which *melody* for voice or instrument was founded. It is remarkable that Aristoxenus, after asserting that the ear is the sole judge of harmonic [melodic] intervals, should have plunged into a system of false calculations of these intervals. He, like the other Greek writers on music, has given us no information regarding the practical parts of the art, either in composition or performance.

Aristoxenus || Arithmetic

ARITHMETIC

Is a science which explains the properties of numbers, and shows the method or art of computing by them.

I.—HISTORY OF ARITHMETIC.

In the early periods of society a vast mound of earth, or a huge block of stone, was the only memorial of any great event; but after the simpler arts came to be known, efforts were made to transmit to posterity the representations of the objects themselves. Sculptures of the humblest kind occur on monumental stones in all parts of the world, sufficient to convey tolerably distinct images of the usual occupation and employments of the personages so commemorated. The next step in the progress of society was to reduce and abridge those rude sculptures, and thence form combinations of figures approaching to the hieroglyphical characters. At this epoch of improvement the first attempts to represent numerals would be made. Instead of repeating the same objects, it was an obvious contrivance to annex to the mere individual the simpler marks of such repetition. Those marks would of necessity be suited to the nature of the materials on which they were inscribed, and the quality of the instruments employed to trace them. In the historical representations, for instance, which the Mexicans and certain Tartar hordes painted on skins, a small coloured circle, as exhibiting the original counter, shell, or pebble, was repeated to denote numbers. But on the Egyptian obelisks the lower numbers, at least, are expressed by combined strokes. Curve lines were not admitted in the earliest rudiments of writing. Even after the use of hieroglyphics had been laid aside, and the artificial system of alphabetic characters adopted, the rectilineal forms were still preferred, as evidently appears in the Greek and Roman capitals, which, being originally of the lapidary sort, are much older than the small or current letters. One of the most ancient sets of characters, the Runic, in which the northern languages were engraved, combines almost exclusively simple strokes at different angles.

The primary numeral traces may, therefore, be regarded as the commencement of a philosophical and universal character, drawn from nature itself, and alike intelligible to all ages and nations. They are still preserved, with very little change, in the Roman notation. Those forms, prior to the adoption of the alphabet itself, were no doubt imported by the Grecian colonies that settled in Italy, and gave rise to the Latin name and commonwealth. Assuming a perpendicular stroke | to signify *one*, another such || would express *two*, the junction of a third ||| *three*, and so repeatedly till the reckoner had reached *ten*. (See Plate LXXII.) The first class was now completed, and to intimate this the carver threw a dash across the stroke or common unit; that is, he employed two decussating strokes X to denote *ten*. He next repeated this mark to express *twenty*, *thirty*, and so forth, till he finished the second class of numbers. Arrived at *an hundred*, he would signify it by joining another dash to the mark for ten, or by merely connecting three strokes thus ⊏. Again, the same spirit of invention might lead him to repeat this character in denoting *two hundred*, *three hundred*, and so forth, till the *third* class was completed. *A thousand*, which begins the fourth class on the *Denary Scale*, was therefore expressed by four combined strokes M, and this was the utmost length to which the Romans first proceeded by direct notation.

But the division of these marks afterwards furnished characters for the intermediate numbers, and hence greatly shortened the repetition of the lower ones. Thus, having parted in the middle the two decussating strokes X denoting *ten*, either the under half Λ, or the upper half V, was employed to signify *five*. Next, the mark ⊏ for an hundred, consisting of a triple stroke, was largely divided into Γ and L, either of which represented *fifty*. Again, the four combined strokes M, which originally formed the character for *a thousand*, came afterwards, in the progress of the arts, to assume a rounded shape ᗰ, frequently expressed thus CIƆ, by two disparted semicircles divided by a diameter. This last form, by abbreviation on either side, gave two portions cI and Iɔ to represent *five hundred*.

Origin of Roman numerals.

It was an easy process, therefore, to devise a universal character for expressing numbers. But the task was very different to reduce the exhibition of language in general to such concise philosophical principles. This attempt seems accordingly to have been early abandoned by all nations except the Chinese. The inestimable advantage of uniting again the whole human race, in spite of the diversity of tongues, by the same permanent system of communication, was sacrificed for the easier attainment of representing by artificial signs those elementary and fugitive sounds into which the words of each particular dialect could be resolved. Hence the Alphabet was invented, which had very nearly attained its present form at the period when the Roman commonwealth was extending its usurpation over Italy. About that epoch a sort of reaction seems to have arisen between the artificial and the natural systems; and the numeral strokes were finally displaced by such alphabetic characters as then most resembled them. (See Plate LXXII.) The ancient Romans employed the letter I to represent the single stroke or mark for *one*; they selected the letter V, since it resembles the upper half of the two decussating strokes or symbol, for *five*; the letter X exactly depicted the double mark for *ten*; again, the letter L was adopted as resem-

History.

bling the divided symbol for *fifty;* while the entire symbol, or the tripled stroke, denoting *an hundred,* was exhibited by the hollow square ⊏, the original form of the letter C before it became rounded over. The quadrupled stroke for a *thousand* was distinctly represented by the letter M, and its variety by the compound character cIↄ, consisting of the letter I inclosed on both sides by C, and by the same letter reversed; a portion of this, again, or Iↄ, being condensed into the letter D, expressed *five hundred.* The letters C and M, beginning the words *Centum* and *Mille,* might have a farther claim to represent an *hundred* and *a thousand;* but the coincidence was merely accidental, since these terms migrated probably from the Greek words ἑκατον and χιλια.

This was the limit of numeration among the early Romans; but, in the progress of refinement, they repeated the symbols of a thousand to denote the higher terms of the Denary Scale. Thus, ccIↄↄ was employed to represent *ten thousand,* and cccIↄↄↄ to signify *an hundred thousand,* the letter I, inclosed between the c ↄ, being, for the sake of greater distinctness, elongated. Again, each of these being divided, gives Iↄↄ for *five thousand,* and Iↄↄↄ for *fifty thousand.* These characters, however, were often modified and abbreviated in monumental inscriptions. By drawing a horizontal line over the letters, their value was augmented *one thousand times.* In the plate so often referred to, we have endeavoured, from the best authorities, to exhibit, under the title of *Lapidary Numerals,* a complete specimen of the various contractions used by stone-cutters among the Romans. It was customary with them, for the sake of abbreviation, to reckon, as rude tribes are apt to do, partly backwards. Thus, instead of *octodecem* and *novemdecem,* the words for *eighteen* and *nineteen,* they frequently used *duodeviginti* and *undeviginti,* as more elegant and expressive. This practice led to the application of *deficient* numbers, an improvement scarcely to be expected from a people so little noted for invention. Instead of writing *nine* thus, VIIII, by joining *four* to *five,* they counted *one* back from *ten,* or placed I before X. In the same way they represented *forty,* and *four hundred, ninety,* and *nine hundred,* by XL, and CD, XC, and CM.

Such, we have no doubt, is the real account of the rise and progress of the Roman numerals. It perfectly agrees with the few hints left us by Aulus Gellius, who expressly says that I and X were anciently represented by one and two strokes; though philologers, misled by partial glimpses, have indeed given a very different statement. Priscian the grammarian, who flourished in the reign of the emperor Justinian, asserts that the mark I was only borrowed from the Athenians, being adopted by them as the principal letter of the word ΜΙΑ, or *one,* the M of which is considered as mute; that V or U was employed by the Romans to denote *five,* because it is the fifth vowel in the common order; that X was assumed to represent *ten,* as being the tenth consonant, and likewise following the V; that L was taken to signify *fifty,* being sometimes interchanged with N, which, as a small letter, expressed that number among the Greeks; that C was adopted to mark *an hundred,* because it is the first letter of the word *centum;* that D, being the next letter of the alphabet, was employed to signify *five hundred;* and that M was borrowed from the Greek letter Χ for ΧΙΛΙΑ, or *a thousand,* only that it was rounded at the ends to distinguish it from the symbol for ten.

After the system of Roman numerals, however, had acquired its full extent, the solicitude of superstition long preserved some traces of the rudest and most primitive mode of chronicling events. At the close of each revolving year, generally on the ides of September, the Prætor Maximus was accustomed, with great ceremony, to drive a *nail* in the door on the right side of the temple of Jupiter, next that of Minerva, the patron of learning and the inventor of numbers. On such occasions they elected a dictator for the sole purpose of driving the sacred nail, and beginning a more propitious year. Hence the expression of Cicero—*Ex hoc die, clavum anni movebis.*

Chinese numerals.

As the Chinese constructed the Swan-pan on the principles of the Roman Abacus (See Abacus), so they likewise, at the remotest epoch of the empire, framed a system of numerals in many respects similar to those which the Romans probably derived from their Pelasgic ancestors. This will appear from the inspection of the characters engraved on Plate LXXII. It is only to be observed that the Chinese mode of writing is the reverse of ours; and that, beginning at the top of the leaf, they descend in parallel columns to the bottom, proceeding, however, from right to left, as practised by most of the Oriental nations.

Instead of the vertical lines used by the Romans, we therefore meet with horizontal ones in the Chinese notation. Thus, *one* is represented by a horizontal stroke, with a sort of barbed termination; *two* by a pair of such strokes; and *three* by as many parallel strokes; the mark for *four* has four strokes, with a sort of flourish; three horizontal strokes, with two vertical ones, form the mark for *five;* and the other symbols exhibit the successive strokes abbreviated, as far as *nine.* *Ten* is figured by a horizontal stroke, crossed with a vertical score, to show that the first rank of the Denary Scale was completed; *an hundred* is signified by two vertical scores, connected by three short horizontal lines; *a thousand* is represented by a sort of double cross; and the other ranks, ascending to *an hundred millions,* have the same marks successively compounded. In addition to the figures in the Plate, we shall here give *fac similes* of a complete set of numerals, printed with metallic types in 1814, at Serampore, in the Elements of Chinese Grammar, by the Reverend Dr Marshman. In these characters, it will be perceived that each symbol has, for the sake of distinction, a small zero or ° annexed to it.

One,	一	*Yih.*	*Ten,*	十	*Shih.*
Two,	二	*Irr.*	*A Hundred,*	百	*Pŭh.*
Three,	三	*San.*	*A Thousand,*	千	*Ts'hyen.*
Four,	四	*Sè.*	*Ten Thousand,*	萬	*Wàn.*
Five,	五	*Ngóo.*	*A hundred Thousand,*	億	*Eè.*
Six,	六	*Lyeù.*	*A Million,*	兆	*Chaò.*
Seven,	七	*Ts'hìh*	*Ten Millions,*	京	*King.*
Eight,	八	*Păh.*	*A hundred Millions,*	垓	*Kyai.*
Nine,	九	*Kyéu.*			

The numbers *eleven, twelve,* &c. are represented by putting the several marks for *one, two,* &c. the excesses above *ten,* immediately below its symbol. But to denote *twenty, thirty,* &c. the marks of the multiples *two, three,* &c. are placed above the symbol for *ten.* This distinction is pursued through all the other cases. Thus, the marks for *two, three,* &c placed over the symbols of *an hundred* or of

History.

a thousand, signify so many *hundreds* or *thousands*. The character for *ten thousand*, called *wàn*, appears to have been the highest known at an early period of the Chinese history; since, in the popular language at present, it is equivalent to *all*. But the Greeks themselves had not advanced farther. In China, *wàn wàn* signifies *ten thousand times ten thousand*, or *an hundred millions;* though there is also a distinct character for this high number. In the eastern strain of hyperbole, the phrase *wàn wàn* far outdoing *a thousand years*, the measure of Spanish loyalty, is the usual shout of long live the emperor! The Chinese character *chaò* for *a million*, though not of the greatest antiquity, is yet as old as the time of Confucius. The characters for *ten* and for *an hundred millions* are not found in their oldest books, but occur in the imperial dictionary.

Such is the very complete but intricate system of Chinese numerals. It has been constantly used, from the remotest times, in all the historical, moral, and philosophical compositions of that singular people. The ordinary symbols for words, or rather things, are, in their writings, generally blended with skill among those characters. But the Chinese merchants and traders have transformed this system of notation into another, which is more concise, and better adapted for the details of business. The changes made on the elementary characters, it will be seen, are not very material. The *one, two,* and *three,* are represented by perpendicular strokes; the symbols for *four* and *five* are altered; *six* is denoted by a short score above an horizontal stroke, as if to signify that *five*, the half of the index of the scale, had been counted over; *seven* and *eight* are expressed by the addition of one and two horizontal lines; and the mark for *nine* is composed of that for *six*, or perhaps at first a variety of *five*, joined to that of *four*.

〡	*One.*
〢	*Two.*
〣	*Three.*
〤	*Four.*
〥	*Five.*
〦	*Six.*
〧	*Seven.*
〨	*Eight.*
〩	*Nine.*

To represent *eleven, twelve,* &c. in this mode, a single stroke is placed on the left of the cross for ten, and the several additions of *one, two,* &c. annexed on the right.

From *twenty* to *an hundred*, the signs of the multiples are prefixed to the mark for *ten*.

〢十	*Twenty.*	〢一 十	*Twenty-one.*
〣十	*Thirty.*	〣一 十	*Thirty-one.*
〤十	*Forty.*	〤一 十	*Forty-one.*
〥十	*Fifty.*	〥一 十	*Fifty-one.*
〧十	*Seventy.*	〧〣 十	*Seventy-three.*

The same method is pursued through the hundreds, the marks of the several multiples being always placed on the left hand before the contracted symbol of *pŭh*, or *an hundred*. The additions are made on the right, with a small cipher or circle (o), called *ling*, when necessary, to separate the place of units. The distinction between *two hundred and three* and *five hundred and thirty* deserves to be particularly remarked.

〢 百	*Two hundred*	〢〇〣 百	*Two hundred and three.*
〥 百	*Five hundred.*	〥〣 百	*Five hundred and thirty.*
〧 百	*Seven hundred.*	〧〨〢 百	*Seven hundred and eighty-two.*

A similar process extends to the notation of thousands, but for ten thousand the character *wàn* is abbreviated. As a specimen of their combination, we select the following complex expression,

〥〤〣〤〧〥〇〇〣
万千百十万

which denotes *five hundred and forty-three millions, four hundred and seventy-five thousand, and three.* The same number would be thus represented in the regular system of Chinese notation:—

零萬四千五
三五十三萬
千七百四

Here the first column on the right hand presents the marks for *fifty* and *four*, with the interjacent character *wàn*, or *ten thousand;* the next column to the left has the several marks for *a thousand, three,* and *an hundred;* the middle column exhibits the symbols of *forty* and of *seven;* the adjacent column repeats the character *wàn*, or *ten thousand*, and then presents those for *five* and *a thousand;* and the last column has the symbol *ling*, or the *rest*, which fills up the blank, with the mark for *three.*

The last expression seems abundantly complicated, and yet it is unquestionably simpler and clearer than the corresponding notation with Roman numerals, as represented below.

IↃↃↃↃↃↃↃ · CCCCCIↃↃↃↃↃ ·
CCCCCIↃↃↃↃↃ · CCCCCIↃↃↃↃↃ ·
CCCCCIↃↃↃↃↃ · CCCCIↃↃↃↃ ·
CCCCIↃↃↃↃ · CCCCIↃↃↃↃ · CCCIↃↃↃ ·
CCCIↃↃↃ · CCCIↃↃↃ · CCCIↃↃↃ
IↃↃↃ · CCIↃↃ · CCIↃↃ · IↃↃ · III.

From such an intricate example, the imperfection of the Roman system will appear the more striking.

The abbreviated process of the Chinese traders was probably suggested by the communication with India, where the admirable system of denary notation has, from the earliest ages, been understood and practised. The adoption of a small cipher to fill the void spaces was a most material improvement on the very complex character *ling*, used formerly for the same purpose.

About the close of the 17th century, the Jesuit missionaries Bouvet, Gerbillon, and others, then residing at the court of Pekin, and able mathematicians, appear to

have still farther improved the numeral symbols of the Chinese traders, and reduced the whole system to a degree of simplicity and elegance of form scarcely inferior to that of our modern ciphers. With these abbreviated characters they printed, at the imperial press, Vlacq's *Tables of Logarithms*, extending to ten places of decimals, in a beautiful volume, of which a copy was presented by Father Gaubil, on his return to Europe, about the year 1750, to the Royal Society of London. From this very curious work, the marks in Plate LXXII. entitled Improved Chinese Numerals, were carefully copied. No more than nine characters, it will be seen, are wanted; the upright cross + for *ten* being a mere redundancy. The marks for *one*, *two*, and *three*, consist of parallel strokes as before; an oblique cross × denotes *four;* and a sort of bisected ten signifies *five*. This symbol again, being contracted into the angular mark ∠, and combined with *one*, *two*, or *three* strokes drawn below it, represents *six*, *seven*, or *eight;* and still more abridged and annexed to the sign of four, it denotes *nine*. The distinction of units, tens, hundreds, &c. is indicated by giving the strokes alternately an horizontal and vertical position, while the blanks or vacant bars are expressed by placing small zeros. The very important collection of logarithmic tables just mentioned was printed by the command of the emperor Kang-hi, a man of enlarged views, who governed China with dignity and wisdom during a long course of years. This enlightened prince was much devoted to the learning of Europe, and is reported to have been so fond of calculation as to have those tables abridged and printed in a smaller character, which precious volume he carried constantly fastened to his girdle. The emperor Kien-long, who, after a beneficent reign of 60 years, in the decline of a protracted life spontaneously resigned the imperial office to his son, discovered a similar taste for the mathematical sciences.

Greek numerals.

The Greeks, after having communicated to the founders of Rome the elements of the numeral characters which are still preserved, again exercised their inventive genius in framing new systems of notation. Discarding the simple original strokes, they sought to draw materials of construction from their extended alphabet. They had no fewer than three different modes of proceeding. 1*st*, The letters of the alphabet, in their natural succession, were employed to signify the smaller ordinal numbers. In this way, for instance, the books of Homer's *Iliad* and *Odyssey* are usually marked. But the practice could scarcely be older than the time of Aristotle, who, it is well known, first collected and arranged those immortal poems, in the edition of the *Casket*, for the use of his illustrious pupil Alexander the Great. 2*d*, The first letters of the words for numerals were adopted as abbreviated symbols. Thus, employing capitals only, Ι, being retained as before, to denote *one*, the letter Π of ΠΕΝΤΕ' marked *five*, the Δ of ΔΕΚΑ denoted *ten*, the Η of ῾ΕΚΑΤΟΝ, anciently written HEKATON, expressed *an hundred*, the Χ of ΧΙΛΙΑ *a thousand*, and the letter Μ of the word ΜΥΡΙΑ represented *ten thousand*. A simple and ingenious device was used for augmenting the powers of those symbols; a large Π placed over any letter made it signify *five thousand* times more. Thus, |Δ| denoted *fifty thousand*, and |Η| *five hundred thousand*. See Plate LXXII. 3*d*, But a mighty stride was afterwards made in numerical notation by the Greeks, when they distributed the twenty-four letters of their alphabet into three classes, corresponding to *units*, *tens*, and *hundreds*. To complete the symbols for the nine digits, an additional character was introduced in each class. The mark ς, called *episêmon*, was inserted among the units, immediately after ε, the letter denoting five; and the *koppa* and *sanpi*, represented by S, ϙ, or ϡ terminated respectively the range of *tens* and of *hundreds*, or expressed ninety and nine hundred. This arrangement of the symbols, it is obvious, could extend only to the expression of nine hundred and ninety-nine; but, by subscribing an *iota* under any character, the value was augmented a thousand fold, or by writing the letter Μ, or the mark for a *myriad*, or ten thousand, under it, the effect was increased ten times more. This last modification was sometimes more simply accomplished by placing two dots over the character.

Such is the beautiful system of Greek numerals, so vastly superior in clearness and simplicity to the Roman combination of strokes. It was even tolerably fitted as an instrument of calculation. Hence the Greeks early laid aside the use of the *abacus;* while the Romans, who never showed any taste for science, were confined, by the total inaptitude of their numerical symbols, to the practice of the same laborious manipulation.

It should, however, be remarked, that the Greeks distinguished the theory from the practice of arithmetic, by separate names. The term *Arithmetic* itself was restricted by them to the science which treats of the nature and general properties of numbers; while the appellation *Logistic* was appropriated to the collection of rules framed to direct and facilitate the common operations of calculation. The ancient systems of arithmetic, accordingly, from the books of Euclid to the treatise of Böethius and the verses or commentaries of Capella, are merely speculative, and often abound with fanciful analogies. Pythagoras had brought from the East a passion for the mystical properties of numbers, under the veil of which he probably concealed some of his secret or esoteric doctrines. He regarded *Numbers* as of divine origin, the fountain of existence, and the model and archetype of all things. He divided them into a variety of different classes, to each of which were assigned distinct properties. They were prime or composite, perfect or imperfect, redundant or deficient, plane or solid; they were triangular, square, cubic, or pyramidal. *Even* numbers were held by that visionary philosopher as feminine, and allied to earth; but the *odd* numbers were considered by him as endued with masculine virtue, and partaking of the celestial nature. He esteemed the *unit*, or *monad*, as the most eminently sacred, and as the parent of all scientific numbers; he viewed *two*, or the *duad*, as the associate of the *monad*, and the mother of the elements; and he regarded *three*, or the *triad*, as perfect, being the first of the masculine numbers, comprehending the beginning, middle, and end, and hence fitted to regulate by its combinations the repetition of prayers and libations. As the *monad* represented the Divinity, or the Creative Power, so the *duad* was the image of Matter; and the *triad*, resulting from their mutual conjunction, became the emblem of Ideal Forms.

Mystical properties of numbers.

But the *tetrad*, or *four*, was the number which Pythagoras affected to venerate the most. It is a square, and contains within itself all the musical proportions, and exhibits by summation all the digits as far as ten, the root of the universal scale of numeration; it marks the seasons, the elements, and the successive ages of man; and it likewise represents the cardinal virtues, and the opposite vices. The ancient division of mathematical science into Arithmetic, Geometry, Astronomy, and Music, was fourfold, and the course was therefore termed a *tetractys* or *quaternion*. Hence, Dr Barrow would explain the oath familiar to the disciples of Pythagoras, "I swear by him who communicated the *Tetractys*."

Five, or the *pentad*, being composed of the first male and female numbers, was styled the number of the world. Repeated anyhow by an odd multiple, it always re-appeared; and it marked the animal senses and the zones of the globe.

History.

Six, or the *hextad*, being composed of its several factors, was reckoned perfect and analogical. It was likewise valued as indicating the sides of the cube, and as entering into the composition of other important numbers.

Seven, or the *heptad*, formed from the junction of the *triad* with the *tetrad*, has been celebrated in every age. Being unproductive, it was dedicated to the virgin Minerva, though possessed of a masculine character. It marked the series of the lunar phases, the number of the planets, and seemed to modify and pervade all nature.

Eight, or the *octad*, being the first cube that occurred, was dedicated to Cybele, the mother of the gods, whose image in the remotest times was only a cubical block of stone.

Nine, or the *ennead*, was esteemed as the square of the *triad*. It denotes the number of the Muses, and, being the last of the series of digits, and terminating the tones of music, it was inscribed to Mars.

Ten, or the *decad*, from the important office which it performs in numeration, was, however, the most celebrated for its properties. Having completed the cycle and begun a new series of numbers, it was aptly styled *apocatastasic* or periodic, and therefore dedicated to the double-faced Janus.

The cube of the *triad*, or the number *twenty-seven*, expressing the time of the moon's periodic revolution, was supposed to signify the power of the lunar circle. The quaternion of celestial numbers, *one, three, five*, and *seven*, joined to that of the terrestrial numbers *two, four, six*, and *eight*, compose the number *thirty-six*, the square of the first perfect number *six*, and the symbol of the universe, distinguished by wonderful properties.

But it would be endless to recount all the visions of the Pythagorean school; nor should we descend to notice such fancies, if, by a perpetual descent, the dreams of ancient philosophers had not, in the actual state of society, still tinctured our language, and mingled with the various institutions of civil life. Not to wander in search of illustration, we see the predilection for the number *seven* strongly marked in the customary term of apprenticeships, in the period required for obtaining academical degrees, and in the legal age of majority.

Numerical fancies of the Chinese.

The Chinese appear, from the remotest epochs of their empire, to have entertained the same admiration of the mystical properties of numbers that Pythagoras imported from the East. Distinguishing numbers into even and odd, they considered the former as terrestrial, and partaking of the feminine principle *Yang;* while they regarded the latter as of celestial extraction, and endued with the masculine principle *Yn*. The even numbers were represented by small black circles, and the odd ones by similar white circles, variously disposed, and connected by straight lines. See Plate LXXII. The sum of the five even numbers *two, four, six, eight*, and *ten*, being *thirty*, was called the number of the *Earth;* but the sum of the five odd numbers *one, three, five, seven*, and *nine*, or *twenty-five*, being the square of *five*, was styled the number of *Heaven*. The nine digits were likewise grouped in two different ways, termed the *Lo-chou* and the *Ho-tou*. The former expression signifies the *Book of the River Lo*, or what the great Yu saw delineated on the back of the mysterious tortoise which rose out of that river: it may be conceived from this arrangement.

	Nine	
Four		*Two*
Three	*Five*	*Seven*
Eight		*Six*
	One	

Nine was reckoned the head, and *one* the tail, of the tortoise; *three* and *seven* were considered as its left and right shoulders; and *four* and *two, eight* and *six*, were viewed as the fore and the hind feet. The number *five*, which represented the heart, was also the emblem of Heaven. We need scarcely observe, that this group of numbers is nothing but the common *magic-square*, each row of which makes up *fifteen*.

As the *Lo-chou* had the figure of a square, so the *Hotou* had that of a cross. It is what the emperor Fou-hi observed on the body of the horse-dragon which he saw spring out of the river Ho. The central number was *ten*, which, it is remarked by the commentators, terminates all the operations on numbers.

		Seven		
		Two		
Five	*Three*	*Ten*	*Four*	*Nine*
		Five		
		One		
		Six		

The Greek system of notation proceeded directly as far as *ten thousand*, comprising four terms of the *Denary Scale;* but by subscribing M, the initial letter of μυϱια, it was carried over another similar period to signify *hundreds of millions*. But the penetrating genius of Archimedes quickly discerned the powers and unfolded the properties of such progressions. In a curious tract, entitled Ψαμμιτης or *Arenarius*, this philosopher amused himself with showing that it was possible, assuming the estimation of Aristarchus of Samos, and other astronomers of that age, to represent the number of particles of sand which would be required to fill the sphere of the universe. He took the limit of the ordinary numeral system, or *ten thousand times ten thousand*, that is, *an hundred millions*, as the root of a new scale of progression, which therefore advanced eight times faster than the simple denary notation. Archimedes proposed to carry this comprehensive system as far as eight periods, which would therefore correspond to a number expressed in our mode by sixty-four digits. From the nature of a geometrical progression, he demonstrated that proportional numbers would range at equal distances, and consequently that the product of any two numbers must have its place determined by the sum of the separate ranks,—a principle which involves the theory of logarithms.

Extended notation proposed by Archimedes,

The fine speculation of the Sicilian philosopher does not, however, appear to have been carried into effect; and without actually performing those calculations, he contents himself by pointing out the process, and stating the approximate results. But Apollonius, the most ingenious and inventive, next to Archimedes, of all the ancient mathematicians, resumed that scheme of numeration, simplified the construction of the scale, and reduced it to a commodious practice. For greater convenience, he preferred the simple myriad as the root of the system, which, therefore, proceeded by successive periods, corresponding to four of our digits. The periods were distinguished by breaks or blanks. That most important office which, in the modern system of notation, the cipher performs, by marking the rank of the digits, was indeed unknown to the earlier Greeks. They were hence obliged, when the lower periods failed, to repeat the letters Μυ. or the contraction for μυϱια, *ten thousand*. Thus, to express *thirty-four trillions*, they wrote λδ Μυ. Μυ. Μυ. To signify *units* separately, it was customary with them to prefix the mark Μ°. or the abbreviation for *monad*.

and by Apollonius.

The procedure of the Greek arithmetician was necessarily slower and more timid than our simple yet refined mode of calculation. Each step in the multiplication of

History.

complex numbers appeared separate and detached, without any concentration which the moderns obtain, by carrying forward the multiples of ten, and blending together the different members of the product. In ancient Greece, the operations of arithmetic, like writing, advanced from left to right; each part of the multiplier was in succession combined with every part of the multiplicand; and the several products were distinctly noted, or, for the sake of compactness, grouped and conveniently dispersed till afterwards collected into one general amount.

Pappus of Alexandria, in his valuable *Mathematical Collections*, has preserved a set of rules which Apollonius had formed, for facilitating arithmetical operations. These are, in the cautious spirit of the ancient geometry, branched out into no fewer than twenty-seven propositions, though all comprised in the principle formerly stated by Archimedes, That the product of two integers of different ranks will occupy a rank corresponding to the sum of the component orders. Suppose μ were to be multiplied into σ, or *forty* into *two hundred:* Take the lower corresponding characters δ and β, or *four* and *two*, which were called πυθμενες or radicals, the one depressed ten times, and the other an hundred times, and multiply their product η, or *eight*, successively by the ten and the hundred, or at once by a thousand, and the result is $\underset{,}{\eta}$ or *eight thousand.*

Greek mode of calculation.

We shall take an example in multiplication, affording more variety than such as occur in Eutocius, which generally consist in the mere squaring of numbers. Let it be required to multiply *eight hundred* and *sixty-two* by *five hundred* and *twenty-three.* The operation would be performed in this way.

$$\begin{array}{r}
\omega\ \xi\ \beta\quad\quad\quad \\
\varphi\ \varkappa\ \gamma\quad\quad\quad \\
\hline
\ddot{\mu}\ \ddot{\gamma}\ \underset{,}{\alpha}\quad\quad\quad\quad\quad\quad\quad \\
\ddot{\alpha}\ \varsigma\quad\quad\quad\quad\quad\quad\quad \\
\underset{,}{\alpha}\ \sigma\ \mu\quad\quad\quad\quad \\
\underset{,}{\beta}\ \upsilon\quad\quad\quad\quad\quad \\
\varrho\ \pi\ \varsigma\quad\quad\quad \\
\hline
\ddot{\mu}\ \ddot{\varepsilon}\quad \omega\ \varkappa\ \varsigma\quad\quad\quad
\end{array}$$

In the first range, φ multiplied into ω, being the same as the product of *eight* and *five* augmented ten thousand times, is consequently denoted by $\ddot{\mu}$ or $\underset{M}{\mu}$; φ multiplied into ξ gives the same result as *five* times *six* increased a thousand fold, and therefore expressed by $\ddot{\gamma}$ or $\underset{M}{\gamma}$; and φ multiplied into β evidently makes a thousand, or $\underset{,}{\alpha}$. In the second range, $\varkappa$ multiplied into ω gives the same product as *eight* repeated *twice* and then augmented a thousand times, or denoted by $\ddot{\alpha}\,\varsigma$; $\varkappa$ multiplied into ξ is equivalent to *six* repeated *twice*, and afterwards increased an hundred fold or, expressed by $\underset{,}{\alpha}\,\sigma$; and $\varkappa$ multiplied by β gives forty, the value of μ. In the third range, γ multiplied into ω produces twenty-four hundred, which is denoted by $\underset{,}{\beta}\,\upsilon$; γ multiplied into ξ makes an hundred and eighty, or $\varrho\,\pi$; and, lastly, γ multiplied into β gives ς, the symbol for *six.* Collecting the scattered members into one sum, the result of the multiplication of *eight hundred and sixty-two* by *five hundred and twenty-three* is $\ddot{\mu}\ \ddot{\varepsilon}\ \omega\ \varkappa\ \varsigma$, or *four hundred and fifty thousand eight hundred and fifty-six.*

But the Greek notation was not adapted for the descending scale. To express fractions, two distinct methods were followed. 1. If the numerator happened to be unit, the denominator was indicated by an accent. Thus δ' signified *one fourth*, and $\varkappa\varepsilon'$ *one twenty-fifth;* but *one half* being of most frequent recurrence, was signified by a particular character, varying in its form, C, ∠, C', or K. 2. In other cases it was the practice of the Greeks to write the denominator as we do an exponent, a little above the denominator, and towards the right hand. Thus, $\beta^{\iota\alpha}$ intimated *two-elevenths*, and $\pi\alpha^{\varrho\varkappa\alpha}$ *eighty-one*, of *an hundred and twenty-one* parts.

As an illustration of the management of fractions, we select an example somewhat complicated, from the commentary which Eutocius of Ascalon wrote about the third century of our era, on the *Tract of Archimedes* concerning the quadrature of the circle. Let it be required to multiply the mixed number *one thousand* and *thirty-eight* with *nine-elevenths*, by itself.

$$\begin{array}{r}
\underset{,}{\alpha}\ \omega\ \lambda\ \eta\quad \theta^{\iota\alpha}\quad\quad \\
\underset{,}{\alpha}\ \omega\ \lambda\ \eta\quad \theta^{\iota\alpha}\quad\quad \\
\hline
\underset{M}{\varrho}\ \underset{M}{\pi}\ \underset{M}{\gamma}\ \underset{,}{\eta}\ \underset{,}{\omega}\ \varsigma\ \eta\quad \beta^{\iota\alpha}\quad\quad \\
\pi\ \underset{M}{\xi\delta}\ \underset{M}{\beta}\ \underset{,}{\delta}\ \underset{,}{\varsigma}\ \upsilon\ \chi\ \nu\ \delta\quad \varsigma^{\iota\alpha}\quad\quad \\
\underset{M}{\gamma}\ \underset{M}{\beta}\ \underset{,}{\delta}\ ϡ\ \sigma\ \mu\ \varkappa\ \delta\quad \varsigma^{\iota\alpha}\quad\quad \\
\underset{,}{\eta}\ \underset{,}{\varsigma}\ \upsilon\ \sigma\ \mu\ \xi\ \delta\ \varsigma\quad \varsigma^{\iota\alpha}\quad\quad \\
\omega\ \iota\ \eta\quad \beta^{\iota\alpha}\quad\quad \\
\chi\ \nu\ \delta\quad \varsigma^{\iota\alpha}\quad\quad \\
\varkappa\ \delta\quad \varsigma^{\iota\alpha}\quad\quad \\
\varsigma\quad \varsigma^{\iota\alpha}\quad\quad \\
\pi\alpha^{\varrho\varkappa\alpha}\quad \\
\hline
\tau\ \underset{M}{\lambda}\ \eta\quad \underset{,}{\alpha}\ \sigma\ \nu\ \alpha\ \zeta^{\iota\alpha}\ \pi\alpha^{\varrho\varkappa\alpha} \\
\text{or, }\tau\ \underset{M}{\lambda}\ \eta\quad \underset{,}{\alpha}\ \sigma\ \nu\ \beta\ \lambda\zeta^{\varrho\varkappa\alpha}\quad\quad
\end{array}$$

It is to be observed, that, to multiply the several integers by the fraction nine-elevenths, amounts to their multiplication by nine, and the subsequent division by eleven. The excesses being *two* and *six-elevenths*, are denoted by $\beta^{\iota\alpha}$ and $\varsigma^{\iota\alpha}$, while the product of the fraction itself gives *eighty-one* of *an hundred and twenty-one* parts, expressed by $\pi\alpha^{\varrho\varkappa\alpha}$.

But the laborious operations that such complex fractions required were afterwards superseded by the use of *sexagesimals*, which, we have already observed, the astronomers, and especially Ptolemy, had introduced. "The division of the circumference of the circle into three hundred and sixty equal parts or degrees was no doubt originally founded on the supposed length of the year, which, expressed in round numbers, consists of twelve months, each composed of thirty days. The radius approaching to the sixth part of the circumference would contain nearly sixty of those degrees; and after its ratio to the circumference was more accurately determined, the radius still continued to be distinguished into the same number of divisions, which likewise bore the same name. As calcu-

lation now aimed at greater accuracy, each of these sixty divisions of the radius was, following the uniform progression, again subdivided into sixty equal portions called minutes; and, repeating the process of sexagesimal subdivision, seconds and thirds were successively formed. The operations with sexagesimal fractions were performed in the descending scale, on a principle quite similar to that which Archimedes had before laid down. Each period of the multiplier, still proceeding from the left hand, was multiplied into a period of the multiplicand; and this product was then thrown to a rank depressed as much as the descents of both its factors. Thus, minutes multiplied into seconds produced thirds; and seconds multiplied into thirds produced fifths." *Edinburgh Review*, vol. xviii. p. 200.

As an exemplification of this process, we shall take the question proposed by Theon to find the square of the side of a regular decagon inscribed in a circle, or the chord of *thirty-six* degrees, which, according to Ptolemy's computation, measured, in sexagesimal parts of the radius, *thirty-seven* degrees, *four* minutes, and *fifty-five* seconds. The multiplication is thus effected:

λζ	δ	νε		
λζ	δ	νε		
͵ατξθ	ρμη	͵βλε		
	ρμη	ις	σκ	
		͵βλε	σκ	
				͵γκε
͵ατοε	δ	ιδ	ι	κε

Here in the first line, λζ multiplied into λζ in the place of units, gives ͵ατξθ or *thirteen hundred and sixty-nine* degrees; λζ into δ on the next bar, gives ρμη, or *one hundred and forty-eight* minutes; and λζ into νε on the lowest bar gives ͵βλε, or *two thousand and thirty-five* seconds. In the second line δ multiplied into λζ gives the product ρμη as before; δ multiplied into δ, both of them on the bar of minutes, gives ις or *sixteen* seconds; δ into νε gives σκ, or *two hundred and twenty* thirds. Lastly, in the third line the νε on the bar of seconds, multiplied successively into λζ and δ, produce, as before, ͵βλε and σκ on the bars of seconds and thirds; and νε multiplied by itself gives ͵γκε, or *three thousand and twenty-five* fourths. These several products being reduced and collected together, formed the total amount of ͵ατοε δ ιδ ι κε, or *thirteen hundred and seventy-five* degrees, *four* minutes, *fourteen* seconds, *ten* thirds, and *twenty-five* fourths; but all the terms below seconds were omitted in practice as insignificant.

This calculation is laborious and intricate, yet with a very few terms it approaches to a considerable degree of accuracy. One of the most elegant theorems in elementary geometry demonstrates that the side of a regular decagon, inscribed in a circle, is equal to the segment of the radius, divided in extreme and mean ratio. Wherefore the square now computed should be equal to the product of *sixty*, or the radius, into *twenty-two* degrees, *fifty-five* minutes, and *five* seconds, the smaller segment; that is, equal to *thirteen hundred* and *seventy-five* degrees and *five* minutes, from which it differs only by the defect of less than one minute.

The Sexagesimal Arithmetic was, therefore, a most valuable improvement engrafted on the notation of the Greeks. The astronomers of Alexandria and Constantinople continued to employ it in all their calculations, and were afterwards imitated by succeeding observers among the Arabians and Persians. The mode of working sexagesimals had thus become generally known and reduced to practice; but we owe the first distinct treatise on those fractions to a very extraordinary character,—Barlaam, a Calabrian monk, the friend and Greek preceptor of the famous Petrarch, and a man of learning and vigorous intellect, who laboured by his writings and his missions to re-unite the Eastern to the Western church. This adventurous personage, whose wayward conduct and dark features betrayed a lurking ferocity, met with a most singular fate. Being overtaken by a tremendous thunder-storm, while crossing the Adriatic Sea, he lashed himself to the mast of the bark, and was, in this situation, struck dead by a flash of lightning. The event happened in 1348; but Barlaam's tract on sexagesimals, neatly composed in six books, after the strict manner of the ancients, and entitled generally Λογιστικη, or *Computation*, first appeared in a Latin version at Strasburg in 1572, though not published complete with the Greek text until the year 1600, when it was edited at Paris by Chambers of Eton, from a manuscript procured from the Continent by the zeal of Sir Henry Savile.

To facilitate the operations with sexagesimals, it seemed indispensable to have a more extensive multiplication table, that should include the mutual products of all the numbers from one to sixty. This was actually constructed about the middle of the sixteenth century by Philip Lansberg, a Dutch clergyman, and has been exhibited since in various forms by Dr Wallis and others. In the mean time a material change had been effected in the subdivision of the radius of the circle, from which the sexagesimal system had taken its rise. Purbach, the great restorer of mathematical science, instead of making the radius to consist of 216,000 seconds, as Ptolemy and succeeding astronomers had done, stopt short at sixty degrees, and distinguished each of these by a repeated centesimal division, into ten thousand equal parts. Regiomontanus advanced a step farther, and, rejecting the sexagesimal admixture, divided the radius at once into a million of parts, thus following out an arrangement purely decimal. The subdivision into degrees, minutes, and seconds, was henceforth confined to the circumference itself; and when logarithms came afterwards to be adapted to those fractions, they received the appellation, once general, though now restricted, of *Logistic*. But the sexagesimal subdivision had nearly been rejected altogether. Our very meritorious countryman Mr Briggs, in computing his canon of logarithms, followed in another branch the example of Purbach, by distinguishing each degree of the circumference into *an hundred* minutes, and each of these again into *an hundred* seconds; and we cannot help regretting that this easy and obvious improvement had not been generally embraced at the time it was proposed. The French mathematicians have lately gone farther, and endeavoured to pursue to its utmost extent the decimal subdivision first introduced by Regiomontanus. They begin with dividing the quadrant into *an hundred* instead of ninety degrees; and then following the plan of Briggs, they successively divide each degree into *an hundred* minutes, and each minute into *an hundred* seconds. But the advantages which might arise from the adoption of this plan are not sufficient perhaps to outweigh the manifest inconvenience that must attend it in the present advanced state of the science; and notwithstanding the sanguine dreams of some of its projectors, we cannot indulge the expectation of ever seeing it obtain a general and durable currency.

"The Greek arithmetic, then, as successively mould-

History.

ed by the ingenuity of Archimedes, of Apollonius, and Ptolemy, had attained, on the whole, to a singular degree of perfection, and was capable, notwithstanding its cumbrous structure, of performing operations of very considerable difficulty and magnitude. The great and radical defect of the system consisted in the want of a general mark analogous to our cipher; and which, without having any value itself, should serve to ascertain the rank or power of the other characters, by filling up the vacant places in the scale of numeration. Yet were the Greeks not altogether unacquainted with the use of such a sign; for Ptolemy, in his *Almagest*, employs the small *o* to occupy the accidental blanks which occurred in the notation of sexagesimals. This letter was perhaps chosen by him, because immediately succeeding to *ν*, which denotes 60, it could not, in the sexagesimal arrangement, occasion any sort of ambiguity. But the advantage thence resulting was entirely confined to that particular case. The letters, being already significant, were generally disqualified for the purpose of a mere supplementary notation; and the selection of an alphabetic character to supply the place of the cipher may be considered as an unfortunate circumstance, which appears to have arrested the progress towards a better and more complete system. Had Apollonius classed the numerals by denary triads instead of tetrads, he would have greatly simplified the arrangement, and avoided the confusion arising from the admixture of the punctuated letters expressing thousands. It is by this method of proceeding with periods of three figures, or advancing at once by thousands instead of tens, that we are enabled most expeditiously to read off the largest numbers. The extent of the alphabet was favourable to the first attempts at enumeration; since, with the help of three intercalations, it furnished characters for the whole range below a thousand; but that very circumstance in the end proved a bar to future improvements. It would have been a most important stride to have next exchanged those triads into monads, by discarding the letters expressive of tens and hundreds, and retaining only the first class, which, with its inserted *episêmon*, should denote the nine digits. The *iôta*, which signified ten, now losing its force, might have been employed as a convenient substitute for the cypher. By such progressive changes the arithmetical notation of the Greeks would at last have reached its utmost perfection, and have exactly resembled our own. A wide interval no doubt did still remain; yet the genius of that acute people, had it continued unfettered, would in time, we may presume, have triumphantly passed the intervening boundaries. But the death of Ptolemy was succeeded by ages of languor and decline; and the spirit of discovery insensibly evaporated in miserable polemical disputes, till the fair establishment of Alexandria was finally overwhelmed under the irresistible arms of the Arabs, lately roused to victory and conquest by the enthusiasm of a new religion." (*Edinburgh Review*, vol. xviii. p. 203.)

History of the denary numerals.

The ingenuity and varied resources of the ancient Greeks were the main causes which diverted them from discovering our simple denary system. Having attained a distinct conception of the powers of the geometrical progression, and even advanced so far as to employ their small o to fill the breaks of a period, nothing seemed wanting but to dismiss the punctuated letters, and those for tens and for hundreds, and to retain merely the direct symbols for units, that is, the first third part of their alphabet. Here, however, those masters of science were stopt in their career; and the Eastern Empire presents a melancholy picture of the decline and corruption of human nature. Ingenuity had degenerated into polemical subtlety, and the manly virtues which freedom inspires were exchanged for meanness and self-abasement.

Some writers, misled by very superficial views of the subject, have yet ascribed the invention of the modern numeral characters to the Greeks, or even to the Romans. Both these people, for the sake of expedition, occasionally used contractions, especially in representing the numbers and fractions of weights or measures, which, to a credulous peruser of mutilated inscriptions, or ancient blurred manuscripts, might appear to resemble the forms of our ciphers. But this resemblance is merely casual, and very far indeed from indicating the adoption of a regular denary notation. The most contracted of the Roman writings was formed by the marks attributed to Tiro or Seneca, while that of the Greeks was mixed with the symbols called *Siglæ;* both of which have exercised the patience and skill of antiquaries and diplomatists. In the latter species of characters were kept the accounts of the revenues of the empress Irene at Constantinople. But the modern Greeks appear likewise to have sometimes used a simpler kind of marks, at least for the low numbers. The continuator of Matthew Paris's *History* relates, that "in the year 1251 died John Basingstoke, archdeacon of Leicester, who brought into England the numeral figures of the Greeks, and explained them to his friends." It is subjoined that they consisted of a perpendicular stroke, with a short line inserted at different heights and at different angles, signifying units on the left and tens on the right side. The figures themselves are scrawled on the margin of the text; but they are evidently so different in their form, and so distinct in their nature, from the modern ciphers, that one cannot help feeling surprise to see an author of any discernment refer the introduction of the latter to Basingstoke.

It cannot be doubted that we derived our knowledge of the numeral digits from the Arabians, who had themselves obtained this invaluable acquisition from their extended communication with the East. Those deserving people who, under the name of Moors or Saracens, had for many centuries cultivated Spain, were most ready to acknowledge their obligation to the natives of India, who, according to Alsephadi, a learned Arabian doctor, boasted of three very different inventions—the composition of the *Golaila Wadamna*, or Pilpay's Fables—the game of chess—and the nine digital characters. Still much obscurity hangs over the whole subject. Two distinct inquiries naturally present themselves:—1, At what period did the Arabians first become acquainted with those characters; and, 2, What is the precise epoch when the knowledge of them was imparted to the Christian nations of Europe. We shall take a short review of both these questions.

Proofs of their Indian origin.

1. Gatterer, the late ingenious and very learned Professor of History at Göttingen, in his *Elements of Universal Diplomacy*, maintains that our ciphers were only primordial letters, invented by Taaut or Theut, and known to the ancient Egyptians and Phœnicians, being still distinctly observed, as he asserts, in the inscriptions painted on the coverings of the oldest mummies; and that afterwards, along with other branches of science, they passed to the Oriental nations, among whom they were preserved, till the victorious arms of the Mussulmans penetrated to India, and brought back those precious monuments of genius. But we cannot believe that a contrivance so very simple, and so eminently useful, as that of the nine digits, if once communicated, could ever again be lost or neglected. Pythagoras and Boethius merely contemplated the properties of numbers, and seem not, in their calculations, to have gone beyond the use of the *Abacus*. An early intercourse had no doubt subsisted between the people of Egypt and of India, and a striking resemblance may be traced in their customs, their buildings, and their

History.

religious rites. But the characters exhibited on the Egyptian monuments bear no indication of the *Denary System*, and are, like the Roman and Chinese numerals, abridged representations of objects, rather than arbitrary signs.

That the occupiers of Hindostan, and the nations communicating with them, have for ages been acquainted with the use of the denary notation, cannot be disputed. But was this an original discovery, or at what distant epoch was it first introduced among them? The easy credulity of European visitors encouraged the Brahmins to set up very lofty pretensions respecting the antiquity of their science. Among other treasures, they boasted the possession, from time immemorial, of an elementary treatise on arithmetic and mensuration, composed in Sanscrit, and called *Lilawati*, of such inestimable value as to be ascribed to the immediate inspiration of heaven. But the researches of our ingenious countrymen in exploring that sacred language of India have dispelled some illusions, and greatly abated the admiration of the public for such eastern learning. From what we have been able to gather, the *Lilawati* is a very short and meagre performance, loaded with a silly preamble and colloquy of the gods. It begins with the numeration by nine digits, and the supplementary cipher or small o, in what are called the *Devanagari* characters; and it contains the common rules of arithmetic, and even the extraction of the square root, as far as two places of figures; but the examples are generally very easy, scarcely forming any part of the text, and only written on the margin with red ink. Of fractions, whether decimal or vulgar, it treats not at all.

The Hindoos pretend that this arithmetical treatise was composed about the year 1185 of the Christian era. The date of a manuscript, however, is always very uncertain. We know, besides, that the oriental transcriber is accustomed to incorporate without scruple such additions in the text as he thinks fit. Nor will any of the criteria which might ascertain the age of a manuscript apply to the eastern writings, where the composition of the paper, the colour of the ink, and the form of the characters, have for ages continued unchanged.

If the exuberant fancy of the Greeks led them far beyond the denary notation, it seems probable that the feebler genius of the Hindoos might just reach that desirable point, without diverging into an excursive flight. Though now familiar with that system, they are still unacquainted with the use of its descending decimal scale; and their management of fractions, accordingly, is said by intelligent judges to be tedious and embarrassed. In Plate LXXII. (on the left hand, and near the bottom), we have given the Sanscrit digits, and have placed over them the numeral elements from which they might be formed. These consist of a succession of simple strokes, variously combined as far as nine. The resemblance to the *Devanagari* characters appears very striking. From these, again, the common Hindoo and the vulgar Bengalee digits are evidently moulded, with only slight alterations of figure. The Birman numerals, which we have copied from Symes's *Embassy to the Kingdom of Ava*, are manifestly of the same origin; only they have a thin, wirey body, being generally written on the palmyra-leaf with the point of a needle.

It appears, from a careful inspection of the manuscripts preserved in the different public libraries of Europe, that the Arabians were not acquainted with the denary numerals before the middle of the thirteenth century of the Christian era. They cultivated the mathematical sciences with ardour, but seldom aspired at original efforts, and generally contented themselves with copying their Grecian masters. The alphabet of the Arabians had been employed for expressing numbers exactly in the same way as that of the Greeks. The letters, in their succession, were sometimes applied to signify the lower of the ordinal numbers; but more generally they were distinguished into three classes, each composed of nine characters, corresponding to units, tens, and hundreds. Though, like most of the Oriental nations, the Arabians write from right to left, yet they followed implicitly the Greek mode of ranging the numerals and performing their calculations. With the same deference they received the other lessons of their great masters, and very seldom hazarded any improvement, unless where industry and patient observation led them incidentally to extend mensuration, and to rectify and enlarge the basis of astronomy.

It seems highly probable, therefore, that the Arabians did not adopt the Indian numerals until a late period, and after the torrent of victory had opened an easy communication with Hindostan. They might derive their information through the medium of the Persians, who spoke a dialect of their language, had embraced the same religion, and were, like them, inflamed by the love of science and the spirit of conquest. The Arabic numerals, accordingly, resemble exceedingly the Persic, which are now current over India, and there esteemed the fashionable characters. But the Persians themselves, though no longer the sovereigns of Hindostan, yet display their superiority over the feeble Gentoos, since they generally fill the offices of the revenue, and have the reputation of being the most expert calculators in the East. It should be observed, however, that, according to Gladwin, these accountants have introduced a peculiar contracted mode of registering very large sums, partly by the numeral characters, and partly by means of symbols formed of abbreviated words. Yet Sir John Chardin relates that the Persians have no proper terms to express numbers beyond a thousand, which they merely repeat, as our young arithmeticians often do, to signify a million or a billion.

The Indian origin of the denary numerals is farther confirmed by the testimony of Maximus Planudes, a monk of Constantinople, who wrote, about the middle of the fourteenth century, a book on practical arithmetic, entitled *Λογιστικη Ινδικη*, or *Ψηφοφορια κατ' Ινδους, ἡ λεγομενη μεγαλη*, that is, "the great Indian mode of calculating." In his introduction he explains concisely the use of the characters in notation. But Planudes appears neither to have received his information directly from India, nor through the medium of the Persians, the nearest neighbours on the eastern confines of the Greek empire. It is most probable that he was made acquainted with those numerals by his intercourse with Europe, having twice visited, on a sort of embassy, the Republic of Venice; for, of two manuscripts preserved in the library of St Mark, the one has the characters of the Arabians, and the other has that variety which was first current in Europe, while neither of them shows the original characters used in Hindostan.

Their introduction into Europe.

2. But the most important inquiry is to ascertain the period at which the knowledge of our present numerals was first spread over Europe. As it certainly had preceded the invention of the art of printing, the difficulty of resolving the question is much increased by the necessity of searching and examining old and often doubtful manuscripts. Some authors would date the introduction of those ciphers as early as the beginning of the eleventh century, while others, with far greater appearance of reason, are disposed to place it 250 years later.

While the thickest darkness brooded over the Christian world, the Arabians, reposing after their brilliant conquests, cultivated with assiduity the learning and science of Greece. If they contributed little from their own

store of genius, they yet preserved and fanned the holy fire. Nor did they affect any concealment, but would freely communicate to their pupils and visitors that precious knowledge which they had so zealously drawn from different quarters. Some of the more aspiring youth in England and France, disgusted with the wretched trifling of the schools, resorted for information to Spain; and having the courage to subdue the rooted abhorrence entertained in that age against infidels, took lessons in philosophy from the accomplished Moors. Among those pilgrims of science, the most celebrated was Gerbert, a monk, born of obscure parents, at Aurillac, in Auvergne, but promoted by his talents successively to the bishoprics of Rheims and of Ravenna, and finally raised to the papal chair, which he filled during the last four years of the tenth century, under the name of Sylvester II. This ardent genius studied arithmetic, geometry, and astronomy among the Saracens; and, on his return to France, charged with various knowledge, he was esteemed a prodigy of learning by his contemporaries. Nor did the malice of rivals fail to represent him as a magician, leagued with the infernal powers. Gerbert wrote largely on arithmetic and geometry, and gave rules for shortening the operations of the *Abacus*, which he likewise termed *Algorismus*. In some manuscripts the numbers are expressed in ciphers; but we are not thence entitled to infer, as many writers have done, that he had actually the merit of introducing those characters into Europe. The context of his discourse will not support such a conclusion. The figures were not, we have seen, still known to the Arabians themselves; and must have long afterwards been inserted in those copies for the convenience of transcribers.

Nor can we safely refer the introduction of Arabic figures to our famous Roger Bacon, whose various attainments and unwearied research after genuine knowledge raised him far above the level of his contemporaries, but who, to the disgrace of his age and country, suffered a sharp persecution and a tedious imprisonment, on the ridiculous charge of practising the redoubted acts of magic. But the writings of Bacon really discover no proofs of his acquaintance with the denary notation; and the fact commonly stated as an irresistible evidence in his favour bears a very different interpretation. An almanack, now preserved in the Bodleian Library at Oxford, and containing numerals in their earliest forms, has, by the credulity of after-times, been, with all other feats and inventions, ascribed of course to the great necromancer. But unluckily this production is marked with the date 1292, the very year on which Bacon, after a lingering illness, expired; and it besides professes to have been calculated for the meridian of Toulouse, and had consequently been imported without doubt from France.[1]

About the same period John of Halifax, named, in the quaint Latinity then used, *Sacro-Bosco*, who had likewise travelled, wrote his treatise *De Sphæra*, in some copies of which the numbers are given in ciphers. But it appears from examination that such abbreviations were introduced by the license of transcribers.

There is little doubt that the Arabic figures were first used by astronomers, and afterwards circulated in the almanacks over Europe. The learned Gerard Vossius places this epoch about the year 1250; but the judicious and most laborious Du Cange thinks that ciphers were unknown before the fourteenth century; and Father Mabillon, whose diplomatic researches are immense, assures us that he very rarely found them in the dates of any writings prior to the year 1400. Kircher, with some air of probability, seeks to refer the introduction of our numerals to the astronomical tables which, after vast labour and expense, were published by the famous Alphonso, king of Castile, in 1252, and again more correctly four years afterwards. But it is suspected that, in the original work, the numbers were expressed in Roman or Saxon characters. Two letters from that enlightened but ill-requited prince, to our Edward I., which are preserved in the Tower of London, have the dates 1272 and 1278 still denoted by those ancient characters.

In the tenth volume of the *Archæologia*, the Rev. Mr North has given a short account of an almanack preserved in the library of Bennet College, Cambridge, and containing a table of eclipses for the cycle between 1330 and 1348. There is prefixed to it a very brief explication of the use of numerals, and the principles of the denary notation; from which we may see how imperfectly the practice of those ciphers was then understood. The figures are of the oldest form, but differ not materially from the present, except that the four has a looped shape, and the five and seven are turned about to the left and to the right. The one, two, three, and four, are likewise, perhaps for elucidation, represented by so many dots thus, . .. ∴ ::; while five, six, seven, and eight, are signified by a semicircle or inverted Ↄ with the addition of corresponding dots—Ↄ. Ↄ: Ↄ∴. Nine is denoted by o; ten by the same character with a dash drawn across it; and twenty, thirty, or forty, by this last symbol repeated.

As a farther evidence of the inaccurate conceptions which prevailed respecting the use of the digits in the fourteenth century, we may refer to the mixture of Saxon and Arabic numerals which was copied from some French manuscripts by Mabillon, as exhibited in Plate LXXII. The Saxon x, signifying ten, is repeatedly combined with the ordinary figures; and xxx, xxxi, are immediately followed by 302, and 303, which must have been therefore intended to signify *thirty-two* and *thirty-three*, the force of the cipher not being still rightly understood. It should be observed, that the Greek *episêmon* or *Fau*, for the number *six*, had come to be represented by a character similar to G. The Saxon dates are taken from the Danish and Norwegian registers, preserved in Suhm's *Northern Collections*.

One of the oldest authentic dates in the numeral characters is that of the year 1375, which appears written by the hand of the famous Petrarch on a copy of St Augustine that had belonged to that distinguished poet and philosopher. The use of those characters had now begun to spread in Europe, but was still confined to men of learning. We have seen a short tract in the German language, entitled *De Algorismo*, and bearing the date 1390, which explained with great brevity the digital notation

[1] Nothing appears to be worse founded than the attempts to represent the elder Bacon in the light of an original inventor. Notwithstanding the obscurity of his writings, it needs but a little criticism to dispel the conceits fomented by national partiality. Friar Bacon advances no claim even to the discovery of gunpowder, which has been so gratuitously ascribed to him. On the contrary, he admits that the boys in his time were acquainted with the use of this substance in fire-works; and he merely pretends, in a sort of anagram, to give a receipt for making it stronger and better than ordinary.

After the chief ingredient in the composition of gunpowder, under the mistaken names of *natron* or *nitrum*, and *saltpetre* or *rock-salt*, had been imported from the East, probably through the intervention of the Crusaders, its disposition to explode in the contact of inflammable matters, if not communicated along with it, could not remain for any time a secret. The explosive force was a very different and a far more important property, which is perhaps rightly attributed to Schwartz, a German monk, who, in the course of his experiments, stumbled on it about the middle of the fourteenth century.

History.

and the elementary rules of arithmetic. What is very remarkable, the characters in their earliest form are ranged thus, 0, 9, 8, 7, 6, 5, 4, 3, 2, 1, from right to left, the order which the Arabians would naturally follow. But it was not very easy to comprehend at first the precise force of the *cipher*, which, insignificant by itself, only serves to determine the rank and value of the other digits. The name, derived from an Arabic word signifying *vacuity*, is sufficiently expressive; yet a sort of mystery, which has imprinted its trace on language, seemed to hang over the practice, for we still speak of *deciphering*, and of *writing in cipher*, in allusion to some dark or concealed art. After the digits had come to supply the place of the Roman numerals, a very considerable time probably elapsed before they were generally adopted in calculation. The modern practice of arithmetic was unknown in England till about the middle of the sixteenth century. But the lower orders, imitating the clerks of a former age, were still accustomed to reckon with their *counters* or *augrym stones*. In Shakspeare's comedy of the *Winter's Tale*, written at the commencement of the seventeenth century, the clown, staggered with a very simple multiplication, exclaims, that he will try it with counters.

Arithmetic was long considered in England as a higher branch of science, and therefore left, like Geometry, to be studied at the university. Most of the public or grammar schools of the south were, on the suppression of the monasteries, erected a little after the Reformation, during the short but auspicious reign of Edward VI. They were accordingly destined by their founders merely for teaching the dead languages; and the too exclusive pursuit of the same system is now one of the greatest defects in the English plan of liberal education.

It cannot be doubted that the calendars composed in France or Germany, and sent to the different religious houses, were the means of dispersing the knowledge of Arabic numerals over Europe. The library of the University of Edinburgh has a very curious almanack, presented to it, with a number of other valuable tracts, by the celebrated Drummond of Hawthornden, beautifully written on vellum, with most of the figures in vermillion. It is calculated especially for the year 1482, but contains the succession of lunar phases for three cycles, 1475, 1494, and 1513, with the visible eclipses of the sun and moon from 1482 to 1530 inclusive. The date of this precious manuscript, which had once belonged to St Mary's Abbey at Cupar in Angus, is easily determined, and we have copied from it the oldest numerals exhibited in Plate LXXII. To these we have subjoined *fac-similes* from Caxton's *Mirrour of the World*, and a wooden cut from Shirwood's *Ludus Arithmomachiæ*, given in Dibdin's *Bibliotheca Spenceriana*.

The college accounts in the English universities were generally kept in the Roman numerals till the early part of the sixteenth century; nor in the parish registers were the Arabic characters adopted before the year 1600. The oldest date which we have met with in Scotland is that of 1490, which occurs in the rent-roll of the diocese of St Andrews; the change from Roman to Arabic numerals occurring, with a corresponding alteration in the form of the writing, near the end of the volume. The old characters in Plate LXXII. are copied from a manuscript history of the Scottish Bishoprics, apparently written about the year 1550.[1] (J. L.)

Notation and Numeration.

II.—OPERATIONS OF ARITHMETIC.

Chap. I.—Notation and Numeration.

The first elements of arithmetic are acquired during our infancy. The idea of *one* is the simplest of any, and is suggested by every single object. *Two* is formed by placing one object near another; *three*, *four*, and every higher number, by adding one continually to the former collection. As we thus advance from lower numbers to higher, we soon perceive that there is no limit to this increasing operation; and that, whatever number of objects be collected together, more may be added, at least in imagination; so that we can never reach the highest possible number, nor approach near it. The idea of numbers, which is first acquired by the observation of sensible objects, is afterwards extended to measures of space and time, affections of the mind, and other immaterial qualities.

Small numbers are most easily apprehended: a child soon knows what *two* and what *three* is, but has not any distinct notion of *seventeen*. Experience removes this difficulty in some degree: as we become accustomed to handle larger collections, we apprehend clearly the number of a dozen or a score; but perhaps could hardly advance to a hundred without the aid of systematic arrangement, which is the art of forming so many units into a class, and so many of these classes into one of a higher kind, and thus advancing through as many ranks of classes as occasion requires. If a boy arrange an hundred stones in one row, he would be tired before he could reckon them; but if he place them in ten rows of ten stones each, he will reckon an hundred with ease; and if he collect ten such parcels, he will reckon a thousand. In this case, ten is the lowest class, a hundred is a class of the second rank, and a thousand is a class of the third rank.

There does not seem to be any number naturally adapted for constituting a class of the lowest or any higher rank, to the exclusion of others. However, as ten has been universally used for this purpose by the Hebrews, Greeks, Romans, and Arabians, and by all nations who have cultivated this science, it is probably the most convenient for general use; but other scales may be assumed, perhaps, on some occasions with superior advantage; and the principles of arithmetic will appear in their full extent, if the student can adapt them to any scale whatever. Thus, if eight were the scale, 6 times 3 would be two classes and two units, and the number 18 would then be represented by 22. If 12 were the scale, 5 times 9 would be three classes and nine units, and 45 would be represented by 39.

Whatever number of units constitutes a class of the lower rank, the same number of each class should make one of the next higher. This is observed in our arithmetic, ten being the universal scale; but it is not regarded in the various kinds of monies, weights, and the like, which do not advance by any universal measure; and much of the difficulty in the practice of arithmetic arises from that irregularity.

[1] For want of attending to these facts, some learned antiquaries have often suffered themselves to be grossly misled. Thus, Mr De Cardonnel, a respectable author, who has given views and short descriptions of the ancient edifices in Scotland, mentions, without marking the smallest doubt or surprise, that the date 1155 appears over the gateway of the ruins of the Castle of St Andrews. But this front was built subsequent to the murder of the detested Cardinal Beaton, by Archibald Hamilton, who likewise there affixed his arms, but who long afterwards, on the capture of Dumbarton Castle, suffered an ignominious death, for his adherence to Queen Mary and the Popish faction. The real date was unquestionably 1555, only the second figure has been almost effaced by time and accident.

Notation and Numeration.

As higher numbers are somewhat difficult to apprehend, we naturally fall on contrivances to fix them in our minds, and render them familiar; but notwithstanding all the expedients we can fall upon, our ideas of high numbers are still imperfect, and generally far short of the reality; and though we can perform any computation with exactness, the answer we obtain is often incompletely apprehended.

It may not be amiss to illustrate, by a few examples, the extent of numbers which are frequently named without being attended to. If a person employed in telling money reckon an hundred pieces in a minute, and continue at work ten hours each day, he will take seventeen days to reckon a million; a thousand men would take 45 years to reckon a billion. If we supposed the whole earth to be as well peopled as Britain, and to have been so from the creation, and that the whole race of mankind had constantly spent their time in telling from a heap consisting of a quadrillion of pieces, they would hardly have yet reckoned the thousandth part of that quantity.

All numbers are represented by the ten following characters.

1	2	3	4	5	6	7	8	9	0
One,	two,	three,	four,	five,	six,	seven,	eight,	nine,	cipher.

The nine first are called *significant figures*, or *digits;* and sometimes represent units, sometimes tens, hundreds, or higher classes. When placed singly, they denote the simple numbers subjoined to the characters; when several are placed together, the first or right-hand figure only is to be taken for its simple value; the second signifies so many tens, the third so many hundreds, and the others so many higher classes, according to the order they stand in. And as it may sometimes be required to express a number consisting of tens, hundreds, or higher classes, without any units or classes of a lower rank annexed, and as this can only be done by figures standing in the second, third, or higher places, while there are none to fill up the lower ones; therefore an additional character or cipher (0) is necessary, which has no signification when placed by itself, but serves to supply the vacant places, and bring the figures to their proper station.

The following table shows the names and divisions of the classes.

8.	Trillions
4	Hundred thousand of billions
3	Ten thousand of billions
7,	Thousand billions
9	Hundred billions
8	Ten billions
2.	Billions
5	Hundred thousand of millions
6	Ten thousand of millions
4,	Thousand millions
7	Hundred millions
3	Ten millions
8.	Millions
9	Hundred thousands
7	Ten thousands
2,	Thousands
6	Hundreds
4	Tens
5.	Units

The first six figures from the right hand are called the *unit period*, the next six the *million period*, after which the *trillion, quadrillion, quintillion, sextillion, septillion, octillion*, and *nonillion* periods follow in their order.

It is proper to divide any number, before we reckon it, into periods and half periods, by different marks. We then begin at the left hand, and read the figures in their order, with the names of their places, from the table. In writing any number, we must be careful to mark the figures in their proper places, and supply the vacant places with ciphers.

Addition.

As there are no possible ways of changing numbers, except by enlarging or diminishing them according to some given rule, it follows that the whole art of arithmetic is comprehended in two operations, *Addition* and *Subtraction.* However, as it is frequently required to add several equal numbers together, or to subtract several equal ones from a greater, till it be exhausted, proper methods have been invented for facilitating the operation in these cases, and distinguished by the names of *Multiplication* and *Division;* and these four rules are the foundation of all arithmetical operations whatever.[1]

As the idea of number is acquired by observing several objects collected, so is that of fractions by observing an object divided into several parts. As we sometimes meet with objects broken into two, three, or more parts, we may consider any or all of these divisions promiscuously, which is done in the doctrine of vulgar fractions. However, since the practice of collecting units into parcels of tens has prevailed universally, it has been found convenient to follow a like method in the consideration of fractions, by dividing each unit into ten equal parts, and each of these into ten smaller parts; and so on. Numbers divided in this manner are called *Decimal Fractions.*

Chap. II.—Addition.

Addition is that operation by which we find the amount of two or more numbers. The method of doing this in simple cases is obvious, as soon as the meaning of number is known, and admits of no illustration. A young learner will begin at one of the numbers, and reckon up as many units separately as there are in the other, and practice will enable him to do it at once. It is impossible, strictly speaking, to add more than two numbers at a time. We must first find the sum of the first and second, then we add the third to that number, and so on. However, as the several sums obtained are easily retained in the memory, it is neither necessary nor usual to mark them down. When the numbers consist of more figures than one, we add the units together, the tens together, and so on. But if the sum of the units exceed ten, or contain ten several times, we add the number of tens it contains to the next column, and only set down the number of units that are over. In like manner we carry the tens of every column to the next higher. And the reason of this is obvious from the value of the places; since an unit, in any higher place, signifies the same thing as ten in the place immediately lower.

Rule.—*Write the numbers distinctly, units under units, tens under tens, and so on. Then reckon the amount of the right-hand column. If it be under ten, mark it down. If it exceed ten, mark the units only, and carry the tens to the next place. In like manner, carry the tens of each column to the next, and mark down the full sum of the left-hand column.*

Example.

```
 346863
 876734
 123467
 314213
 712316
 438987
 279654
-------
3092234
  24433
```

As it is of great consequence in business to perform addition readily and exactly, the learner ought to practise it till it become quite familiar. If the learner can readily add any two digits, he will soon add a digit to a higher number with equal ease. It is only to add the unit place

[1] To abbreviate, it is sometimes convenient to indicate the four operations of arithmetic by the signs +, —, ×, ÷. The first, +, denotes addition; the second, —, indicates subtraction; the third, ×, multiplication; and the fourth, ÷ division. The sign = put between two quantities indicates that they are equal. Accordingly we may write $2 + 3 = 5$; $7 - 3 = 4$; $5 \times 3 = 15$; $14 \div 2 = 7$.

Addition.

of that number to the digit; and if it exceed ten, it raises the amount accordingly. Thus, because 8 and 6 are 14, 48 and 6 are 54. It will be proper to mark down under the sums of each column, in a small hand, the figure that is carried to the next column. This prevents the trouble of going over the whole operation again, in case of interruption or mistake. If you wish to keep the account clean, mark down the sum and figure you carry on a separate paper, and after revising them, transcribe the sum only. After some practice, we ought to acquire the habit of adding two or more figures at one glance. This is particularly useful when two figures which amount to 10, as 6 and 4, or 7 and 3, stand together in the column.

Every operation in arithmetic ought to be revised, to prevent mistakes; and as one is apt to fall into the same mistake, if he revise it in the same manner he performed it, it is proper either to alter the order, or else to trace back the steps by which the operation advanced, which will lead us at last to the number we began with. Every method of proving accounts may be referred to one or other of these heads.

1*st*, Addition may be proved by any of the following methods: Repeat the operation, beginning at the top of the column, if you began at the foot when you wrought it.

2*d*, Divide the account into several parts; add these separately, and then add the sums together. If their amount correspond with the sum of the account when added at once, it may be presumed right. This method is particularly proper when you want to know the sums of the parts as well as that of the whole.

3*d*, Subtract the numbers successively from the sum; if the account be right, you will exhaust it exactly, and find no remainder.

When the given number consists of articles of different value, as pounds, shillings, and pence, or the like, which are called *different denominations*, the operations in arithmetic must be regulated by the value of the articles. We shall give here a few of the most useful tables.

I. *Sterling Money.*	II. *Avoirdupois Weight.*
4 farthings = 1 penny, *marked* d.	16 drams = 1 ounce, oz.
12 pence = 1 shilling, s.	16 ounces = 1 pound, lb.
20 shillings = 1 pound, £.	28 pounds = 1 quarter, qr.
Also 6s. 8d. = 1 noble.	4 quart. = 1 hundredw^{t}, cwt.
12s. = 1 angel.	20 hundredw^{t} = 1 ton, T.
13s. 4d. or two thirds of a pound = 1 merk.	

Scots money is divided in the same manner as sterling, and has one twelfth of its value. A pound Scots is equal to 1s. 8d. sterling, a shilling Scots to a penny sterling, and a penny Scots to a twelfth part of a penny sterling; a merk Scots is two thirds of a pound Scots, or $13\frac{1}{3}$d. sterling.

III. *Troy Weight.*	IV. *Apothecaries' Weight.*
20 mites = 1 grain, gr.	20 grains = 1 scruple, ℈
24 grains = 1 pennyw^{t}, dwt.	3 scruples = 1 dram, ʒ
20 pennyw^{ts} = 1 ounce, oz.	8 drams = 1 ounce, ℥
12 ounces = 1 pound, lib.	12 ounces = 1 pound, ℔

V. *English Dry Measure.*	VI. *Scots Dry Measure.*
2 pints = 1 quart	4 lippies = 1 peck
4 quarts = 1 gallon	4 pecks = 1 firlot
2 gallons = 1 peck	4 firlots = 1 boll
4 pecks = 1 bushel	16 bolls = 1 chalder
8 bushels = 1 quarter	

VII. *English Land Measure.*	VIII. *Scots Land Measure.*
$30\frac{1}{4}$ square yards = 1 pole or perch	36 square ells = 1 fall
40 poles = 1 rood	40 falls = 1 rood
4 roods = 1 acre	4 roods = 1 acre

IX. *Long Measure.*	X. *Time.*
12 inches = 1 foot	60 seconds = 1 minute
3 feet = 1 yard	60 minutes = 1 hour
$5\frac{1}{2}$ yards = 1 pole	24 hours = 1 day
40 poles = 1 furlong	7 days = 1 week
8 furlongs = 1 mile	365 days = 1 year
3 miles = 1 league	52 weeks and 1 day = 1 year

Rule for Compound Addition.—*Arrange like quantities under like, and carry according to the value of the higher place.*

Note 1. When you add a denomination which contains more columns than one, and from which you carry to the higher by 20, 30, or any even number of tens, first add the units of that column, and mark down their sum, carrying the tens to the next column; then add the tens, and carry to the higher denomination, by the number of tens that it contains of the lower. For example, in adding shillings, carry by 10 from the units to the tens, and by 2 from the tens to the pounds.

Note 2. If you do not carry by an even number of tens, first find the complete sum of the lower denomination, then inquire how many of the higher that sum contains, and carry accordingly, and mark the remainder, if any, under the column. For example, if the sum of a column of pence be 43, which is three shillings and sevenpence, mark 7 under the pence column, and carry 3 to that of the shillings.

Note 3. Some add the lower denominations after the following method: when they have reckoned as many as amounts to one of the higher denomination, or upwards, they mark a dot, and begin again with the excess of the number reckoned above the value of the denomination. The number of dots shows how many are carried, and the last reckoned number is placed under the column.

Examples.

Sterling Money.

£	s.	d.
127	13	3
43	5	$10\frac{1}{2}$
806	18	7
190	2	$5\frac{3}{4}$
214	0	3
85	15	$4\frac{1}{2}$
1467	15	$9\frac{3}{4}$

Avoirdupois Weight.

T.	cwt.	qr.	lb.
3	15	2	24
6	3	0	19
5	7	3	26
3	2	2	0
4	3	1	10
1	18	1	12
24	11	0	7

Chap. III.—Subtraction.

Subtraction.

Subtraction is the operation by which we take a lesser number from a greater, and find their difference. It is exactly opposite to addition, and is performed in a like manner, beginning at the greater, and reckoning downwards the units of the lesser. The greater is called the *minuend*, and the lesser the *subtrahend*.

If any figure of the subtrahend be greater than the corresponding figure of the minuend, we add ten to that of the minuend, and having found and marked the difference, we add one to the next place of the subtrahend. This is called *borrowing ten*. The reason will appear, if we consider that, when two numbers are equally increased by adding the same to both, their difference will not be altered. When we proceed as directed above, we add ten to the minuend, and we likewise add one to the higher place of the subtrahend, which is equal to ten of the lower place.

Rule.—*Subtract units from units, tens from tens, and so on. If any figure of the subtrahend be greater than the corresponding one of the minuend, borrow ten.*

Example.		
Minuend	173694	738641
Subtrahend	21453	379235
Remainder	152241	359406

Subtraction.

To prove subtraction, add the subtrahend and remainder together; if their sum be equal to the minuend, the account is right.

Or subtract the remainder from the minuend. If the difference be equal to the subtrahend, the account is right.

Rule for Compound Subtraction.—*Place like denominations under like; and borrow, when necessary, according to the value of the higher place.*

Examples.

£	s.	d.	Cwt.	qr.	lib.	A.	R.	F	E.
146	3	3	12	3	19	15	2	24	18
58	7	6	4	3	24	12	2	36	7
87	15	9	7	3	23	2	3	28	11

Note 1. The reason for borrowing is the same as in simple subtraction. Thus, in subtracting pence, we add 12 pence when necessary to the minuend, and at the next step we add one shilling to the subtrahend.

Note 2. When there are two places in the same denomination, if the next higher contain exactly so many tens, it is best to subtract the units first, borrowing ten when necessary; and then subtract the tens, borrowing, if there is occasion, according to the number of tens in the higher denomination.

Note 3. If the value of the higher denomination be not an even number of tens, subtract the units and tens at once, borrowing according to the value of the higher denomination.

Note 4. Some choose to subtract the place in the subtrahend, when it exceeds that of the minuend, from the value of the higher denomination, and add the minuend to the difference. This is only a different order of proceeding, and gives the same answer.

Multiplication.

Note 5. As custom has established the method of placing the subtrahend under the minuend, we follow it when there is no reason for doing otherwise; the minuend may be placed under the subtrahend with equal propriety; and the learner should be able to work it either way with equal readiness, as this last is sometimes more convenient, of which instances will occur afterwards.

Note 6. The learner should also acquire the habit, when two numbers are marked down, of placing such a number under the lesser, that, when added together, the sum may be equal to the greater. The operation is the same as subtraction, though conceived in a different manner, and is useful in balancing accounts and on other occasions.

Chap. IV.—Multiplication.

In multiplication two numbers are given, and it is required to find how much the first amounts to when reckoned as many times as there are units in the second. Thus, 8 multiplied by 5, or 5 times 8, is 40. The given numbers (8 and 5) are called *factors*, the first (8) the *multiplicand*, the second (5) the *multiplier*, and the amount (40) the *product*.

This operation is nothing else than addition of the same number several times repeated. If we mark 8 five times under each other, and add them, the sum is 40. But as this kind of addition is of frequent and extensive use, in order to shorten the operation, we mark down the number only once, and conceive it to be repeated as often as there are units in the multiplier.

For this purpose the learner must be thoroughly acquainted with the following multiplication table, which is composed by adding each digit twelve times.

Twice		Thrice		Four times		Five times		Six times		Seven times		Eight times		Nine times		Ten times		Eleven times		Twelve times	
1 is	2	1 is	3	1 is	4	1 is	5	1 is	6	1 is	7	1 is	8	1 is	9	1 is	10	1 is	11	1 is	12
2	4	2	6	2	8	2	10	2	12	2	14	2	16	2	18	2	20	2	22	2	24
3	6	3	9	3	12	3	15	3	18	3	21	3	24	3	27	3	30	3	33	3	36
4	8	4	12	4	16	4	20	4	24	4	28	4	32	4	36	4	40	4	44	4	48
5	10	5	15	5	20	5	25	5	30	5	35	5	40	5	45	5	50	5	55	5	60
6	12	6	18	6	24	6	30	6	36	6	42	6	48	6	54	6	60	6	66	6	72
7	14	7	21	7	28	7	35	7	42	7	49	7	56	7	63	7	70	7	77	7	84
8	16	8	24	8	32	8	40	8	48	8	56	8	64	8	72	8	80	8	88	8	96
9	18	9	27	9	36	9	45	9	54	9	63	9	72	9	81	9	90	9	99	9	108
10	20	10	30	10	40	10	50	10	60	10	70	10	80	10	90	10	100	10	110	10	120
11	22	11	33	11	44	11	55	11	66	11	77	11	88	11	99	11	110	11	121	11	132
12	24	12	36	12	48	12	60	12	72	12	84	12	96	12	108	12	120	12	132	12	144

If both factors be under 12, the table exhibits the product at once. If the multiplier only be under 12, we begin at the unit place and multiply the figures in their order, carrying the tens to the higher place, as in addition.

Ex. 76859 multiplied by 4, or 76859 added 4 times.

$$\begin{array}{r} 76859 \\ 4 \\ \hline 307436 \end{array} \qquad \begin{array}{r} 76859 \\ 76859 \\ 76859 \\ 76859 \\ \hline 307436 \end{array}$$

If the multiplier be 10, we annex a cipher to the multiplicand; if the multiplier be 100, we annex two ciphers, and so on. The reason is obvious, from the use of ciphers in notation.

If the multiplier be any digit, with one or more ciphers on the right hand, we multiply by the figure, and annex an equal number of ciphers to the product. Thus, if it be required to multiply by 50, we first multiply by 5, and then annex a cipher. It is the same thing as to add the multiplicand 50 times; and this might be done by writing the account at large, dividing the column into 10 parts of 5 lines, finding the sum of each part, and adding these ten sums together.

If the multiplier consists of several significant figures, we multiply separately by each, and add the products. It is the same as if we divided a long account of addition into parts corresponding to the figures of the multiplier.

Example. To multiply 7329 by 365.

$$\begin{array}{r} 7329 \\ 5 \\ \hline 36645 \end{array} \qquad \begin{array}{r} 7329 \\ 60 \\ \hline 439740 \end{array} \qquad \begin{array}{r} 7329 \\ 300 \\ \hline 2198700 \end{array} \qquad \begin{array}{rl} 36645 = & 5 \text{ times.} \\ 439740 = & 60 \text{ times.} \\ 2198700 = & 300 \text{ times.} \\ \hline 2675085 = & 365 \text{ times.} \end{array}$$

It is obvious that 5 times the multiplicand added to 60 times, and to 300 times the same, must amount to the product required. In practice we place the products at once under each other; and as the ciphers arising from the higher places of the multiplier are lost in the addition, we omit them. Hence may be inferred the following

Multiplication.

Rule.—*Place the multiplier under the multiplicand, and multiply the latter successively by the significant figures of the former, placing the right-hand figure of each product under the figure of the multiplier from which it arises, then add the product.*

Ex.				
	7329	42785	37846	93956
	365	91	235	8704
	36645	42785	189230	375824
	43974	385065	113538	657692
	21987	3893435	75692	751648
	2675085		8893810	817793024

A number which cannot be produced by the multiplication of two others is called a *prime number;* as 3, 5, 7, 11, and many others.

A number which may be produced by the multiplication of two or more smaller ones, is called a *composite number;* for example, 27, which arises from the multiplication of 9 by 3; and these numbers, 9 and 3, are called the *component parts* of 27.

Contractions and Varieties in Multiplication.

1*st,* If the multiplier be a composite number, we may multiply successively by the component parts.

Ex.	7638 by 45, or 5 times 9	7638
	45	9
	38190	68742
	30552	5
	343710	343710

Because the second product is equal to five times the first, and the first is equal to nine times the multiplicand, it is obvious that the second product must be five times nine, or forty-five times as great as the multiplicand.

2*dly,* If the multiplier be 5, which is the half of 10, we may annex a cipher and divide by 2. If it be 25, which is the fourth part of 100, we may annex two ciphers and divide by 4. Other contractions of the like kind will readily occur to the learner.

3*dly,* To multiply by 9, which is one less than 10, we may annex a cipher, and subtract the multiplicand from the number it composes. To multiply by 99999, or any number of 9's, annex as many ciphers, and subtract the multiplicand. The reason is obvious; and a like rule may be found though the unit place be different from 9.

4*thly,* Sometimes a line of the product is more easily obtained from a former line of the same than from the multiplicand.

Ex. 1*st.*	1372	2*d.*	1348
	84		36
	5488		8088
	10976		4044
	115248		48528

In the first example, instead of multiplying by 8, we may multiply 5488 by 2; and, in the second, instead of multiplying by 3, we may divide 8088 by 2.

5*thly,* Sometimes the product of two or more figures may be obtained at once, from the product of a figure already found.

Ex. 1*st.*	14356	2*d.*	3462321
	648		96484
	114848		13849284
	918784		166191408
	9302688		332382816
			334058579364

In the second example we multiply first by 4, then, because 12 times 4 is 48, we multiply the first line of the product by 12, instead of multiplying separately by 8 and 4; lastly, because twice 48 is 96, we multiply the second line of the product by 2, instead of multiplying separately by 6 and 9.

When we follow this method, we must be careful to place the right-hand figure of each product under the right-hand figure of that part of the multiplier which it is derived from.

It would answer equally well in all cases to begin the work at the highest place of the multiplier; and contractions are sometimes obtained by following that order.

Ex. 1*st.*	3125	or	3125	2*d.*	32452
	642		642		52575
	18750		18750		162260
	12500		131250		811300
	6250		2006250		2433900
	2006250				1706163900

It is a matter of indifference which of the factors be used as the multiplier; for 4 multiplied by 3 gives the same product as 3 multiplied by 4; and the like holds universally true. To illustrate this, we may make three rows of points, four in each row, placing the rows under each other; and we shall have also four rows containing three points each, if we reckon the rows downwards.

. . . .
. . . .
. . . .

Multiplication is proved by repeating the operation, using the multiplier for the multiplicand, and the multiplicand for the multiplier. It may also be proven by division, or by casting out the 9's, of which afterwards; and an account, wrought by any contraction, may be proven by performing the operation at large, or by a different contraction.

Compound Multiplication.

Rule I.—*If the multiplier do not exceed* 12, *the operation is performed at once, beginning at the lowest place, and carrying according to the value of the place.*

Examples.

£	s.	d.	Cwt.	qr.	lb.	A.	R.	P.	Lb.	oz.	dwt.
13	6	7	12	2	8	13	3	18	7	5	9
		9			5			6			12
119	19	3	62	3	12	83	0	28	89	5	8

Rule II.—*If the multiplier be a composite number, whose component parts do not exceed* 12, *multiply first by one of these parts, then multiply the product by the other. Proceed in the same manner if there be more than two.*

Ex. 1*st.*	£15	3	8	by 32 = 8 × 4
			8	
	£121	9	4	= 8 times.
			4	
	£485	17	4	= 32 times.
2*d.*	£17	3	8	by 75 = 5 × 5 × 3
			3	
	£51	11	–	= 3 times.
			5	
	£257	15	–	= 15 times.
			5	
	£1288	15	–	= 75 times.

Note 1. Although the component parts will answer in any order, it is best, when it can be done, to take them in such order as may clear off some of the lower places at the first multiplication, as is done in *Ex.* 2*d.*

Note 2. The operation may be proved by taking the

Reduction. component parts in a different order, or dividing the multiplier in a different manner.

Rule III.—*If the multiplier be a prime number, multiply first by the composite number next lower, then by the difference, and add the products.*

£	s.	d.	
£35	17	9	by 67 = 64+3
		8	64 = 8×8
£287	2	–	= 8 times.
		8	
£2296	16	–	= 64 times.
107	13	3	= 3 times.
£2404	9	3	= 67 times.

Here, because 8 times 8 is 64, we multiply twice by 8, which gives £2296. 16s. equal to 64 times the multiplicand: then we find the amount of 3 times the multiplicand, which is £107. 13s. 3d.; and it is evident that these added amount to 67 times the multiplicand.

Rule IV.—*If there be a composite number a little above the multiplier, we may multiply by that number, and by the difference, and subtract the second product from the first.*

£	s.	d.	
£17	4	5	by 106 = 108 — 2
		12	108 = 9 × 12
£206	13	–	
		9	
£1859	17	–	= 108 times.
34	8	10	= 2 times.
£1825	8	2	= 106 times.

Here we multiply by 12 and 9, the component parts of 108, and obtain a product of £1859. 17s. equal to 108 times the multiplicand; and, as this is twice oftener than was required, we subtract the multiplicand doubled, and the remainder is the number sought.

Rule V.—*If the multiplier be large, multiply by* 10, *and multiply the product again by* 10; *by which means you obtain an hundred times the given number. If the multiplier exceed* 1000, *multiply by* 10 *again; and continue it farther if the multiplier require it; then multiply the given number by the unit-place of the multiplier; the first product by the ten-place, the second product by the hundred-place, and so on. Add the products thus obtained together.*

	£34	8	2¼ by 5 =	£172	1	0¼	=	5 times.
			10					
10 times	£344	2	1 by 6 =	2064	12	6	=	60 times.
			10					
100 times	£3441	–	10 by 4 =	13764	3	4	=	400 times.
			10					
1000 times	£34410	8	4 by 3 =	103231	5	–	=	3000 times.
				£119232	1	10¼	=	3465 times.

The use of multiplication is to compute the amount of any number of equal articles, either in respect of measure, weight, value, or any other consideration. The multiplicand expresses how much is to be reckoned for each article, and the multiplier expresses how many times that is to be reckoned. As the multiplier points out the number of articles to be added, it is always an abstract number, and has no reference to any value or measure whatever. It is therefore quite improper to attempt the multiplication of shillings by shillings, or to consider the multiplier as expressive of any denomination.

Reduction.

Reduction is the computation for changing any sum of money, weight, or measure, into a different kind. When the quantity given is expressed in different denominations, we reduce the highest to the next lower, and add thereto the given number of that denomination; and proceed in like manner till we have reduced it to the lowest denomination.

Division.

Ex. To reduce £46. 13s. 8¾d. to farthings.

£46	
20	
920	shillings in £46
13	
933	shillings in £46 13
12	
11196	pence in £46 13
8	
11204	pence in £46 13 8
4	
44816	farthings in £46 13 8
3	
44819	farthings in £46 13 8¾

Or thus:

£46 13 8¾.
20
933
12
11204
4
44819

It is easy to take in or add the lower denomination at the same time that we multiply the higher.

Chap. V.—Division.

In division two numbers are given, and it is required to find how often the former contains the latter. Thus, it may be asked how often 21 contains 7, and the answer is exactly 3 times. The former given number (21) is called the *dividend*, the latter (7) the *divisor*, and the number required (3) the *quotient*. It frequently happens that the division cannot be completed exactly without fractions. Thus it may be asked, how often 8 is contained in 19? the answer is twice, and the remainder of 3.

This operation consists in subtracting the divisor from the dividend, and again from the remainder, as often as it can be done, and reckoning the number of subtractions; as,

21	19
7 first subtraction	8 first subtraction
14	11
7 second subtraction	8 second subtraction
7	3 remainder.
7 third subtraction.	
0	

As this operation, performed at large, would be very tedious when the quotient is a high number, it is proper to shorten it by every convenient method; and for this purpose we may multiply the divisor by any number whose product is not greater than the dividend, and so subtract it twice or thrice, or oftener, at the same time. The best way is to multiply it by the greatest number that does not raise the product too high, and that number is also the quotient. For example, to divide 45 by 7, we inquire what is the greatest multiplier for 7 that does not give a product above 45, and we shall find that it is 6; and 6 times 7 is 42, which, subtracted from 45, leaves a remainder of 3. Therefore 7 may be subtracted 6 times from 45; or, which is the same thing, 45 divided by 7, gives a quotient of 6 and a remainder of three.

If the divisor do not exceed 12, we readily find the highest multiplier that can be used from the multiplication table. If it exceed 12, we may try any multiplier that we think will answer. If the product be greater than the dividend, the multiplier is too great; and if the remainder, after the product is subtracted from the dividend, be greater than the divisor, the multiplier is too small. In either of these cases we must try another. But the attentive learner, after some practice, will generally hit on the right multiplier at first.

If the divisor be contained oftener than ten times in the dividend, the operation requires as many steps as

there are figures in the quotient. For instance, if the quotient be greater than 100, but less than 1000, it requires 3 steps. We first inquire how many hundred times the divisor is contained in the dividend, and subtract the amount of these hundreds. Then we inquire how often it is contained ten times in the remainder, and subtract the amount of these tens. Lastly, we inquire how many single times it is contained in the remainder. The method of proceeding will appear from the following example:

To divide 5936 by 8.

```
          From  5936
          Take  5600 = 700 times 8.
                ----
          Rem.   336
From which take  320 =  40 times 8.
                ----
          Rem.    16
From which take   16 =   2 times 8.
                ----    ---
                   0    742 times 8 in all.
```

It is obvious, that as often as 8 is contained in 59, so many hundred times it will be contained in 5900, or in 5936; and as often as it is contained in 33, so many ten times it will be contained in 330, or in 336; and thus the higher places of the quotient will be obtained with equal ease as the lower. The operation might be performed by subtracting 8 continually from the dividend, which will lead to the same conclusion by a very tedious process. After 700 subtractions, the remainder would be 336; after 40 more it would be 16; and after 2 more the dividend would be entirely exhausted. In practice we omit the ciphers, and proceed by the following

RULES.—1. *Assume as many figures on the left hand of the dividend as contain the divisor once or oftener; find how many times they contain it, and place the answer as the highest figure of the quotient.*

2. *Multiply the divisor by the figure you have found, and place the product under the part of the dividend from which it is obtained.*

3. *Subtract the product from the figures above it.*

4. *Bring down the next figure of the dividend to the remainder, and divide the number it makes up as before.*

Examples.] 1*st,*

       365
       ---
Remainder 17
```

The numbers which we divide, as 59, 33, and 16, in the first example, are called *dividuals.*

It is usual to mark a point under the figures of the dividend as they are brought down, to prevent mistakes.

If there be a remainder, the division is completed by a vulgar fraction, whose numerator is the remainder, and its denominator the divisor. Thus, in Ex. 3 the quotient is 2671, and the remainder 17; and the quotient completed is 2671 $\frac{17}{365}$.

A number which divides another without a remainder is said to measure it; and the several numbers which measure another are called its *aliquot parts.* Thus 2, 4, 6, 8, and 12, are aliquot parts of 24. As it is often useful to discover numbers which measure others, we may observe,

1*st,* Every number ending with an even figure, that is, with 2, 4, 6, 8, or 0, is measured by 2.

2*dly,* Every number ending with 5 or 0 is measured by 5.

3*dly,* Every number whose figures, when added, amount to an even number of 3's or 9's, is measured by 3 or 9, respectively.

Contractions and Varieties in Division.

1*st,* When the divisor does not exceed 12, the whole computation may be performed without setting down any figures except the quotient.

Ex. 7)35868(5124 or

```
7)35868
  -----
   5124
```

2*dly,* When the divisor is a composite number, and one of the component parts also measures the dividend, we may divide successively by the component parts.

Ex. 1*st,*] 30114 by 63

```
         9)30114
         7) 3346
Quotient     478
```

2*d,*] 975 by 105 = 5 × 7 × 3

```
         5)975
         3)195
         7) 65
Quotient    9 2/7
```

This method might be also used although the component parts of the divisor do not measure the dividend; but the management of the remainder requires the doctrine of vulgar fractions.

3*dly,* When there are ciphers annexed to the divisor, cut them off, and cut off an equal number of figures from the dividend; annex those figures to the remainder.

Ex. To divide 378643 by 5200.

```
52|00)3786|43(724 4243/5200.
      364·
      ---
       146
       104
       ----
       4243
```

The reason will appear by performing the operation at large, and comparing the steps.

To divide by 10, 100, 1000, or the like: Cut off as many figures on the right hand of the dividend as there are ciphers in the divisor. The figures which remain on the left hand compose the quotient, and the figures cut off compose the remainder.

Note.—Since 4 times 25 make 100, instead of dividing by 25, we may multiply the dividend by 4, and cut off the two last figures from the product. The figures left will be the quotient, and those cut off the remainder. In like manner, to divide by 125, which multiplied by 8 produces 1000, we may multiply the dividend by 8, and cut off three figures, which will be the remainder, and those left the quotient.

4*thly,* When the divisor consists of several figures, we may try them separately, by inquiring how often the first figure of the divisor is contained in the first figure of the dividend, and then considering whether the second and following figures of the divisor be contained as often in the corresponding ones of the dividend with the remainder (if any) prefixed. If not, we must begin again, and make trial of a lower number. When the remainder is nine or upwards, we may be sure the division will hold through the lower places; and it is unnecessary to continue the trial farther.

5*thly,* We may make a table of the products of the divisor, multiplied by the nine digits, in order to discover more readily how often it is contained in each dividual. This is convenient when the dividend is very long, or when it is required to divide frequently by the same divisor.

```
73 by 2 = 146        73)53872694(737982
      3 = 219           511·····
      4 = 292           ---
      5 = 365            277
      6 = 438            219
      7 = 511            ---
      8 = 584             582
      9 = 657             511
                          ---
                           716
                           657
                           ---
                            599
                            584
                            ---
                             154
                             146
                             ---
                     Rem.      8
```

6*thly*, To divide by 9, 99, 999, or any number of 9's, transcribe under the dividend part of the same, shifting the highest figure as many places to the right hand as there are 9's in the divisor. Transcribe it again, with the like change of place, as often as the length of the dividend admits; add these together, and cut off as many figures from the right hand of the sum as there are 9's in the divisor. The figures which remain on the left hand compose the quotient, and those cut off the remainder.

If there be any carriage to the unit place of the quotient, add the number carried likewise to the remainder, as in Ex. 2; and if the figures cut off be all 9's, add 1 to the quotient, and there is no remainder.

```
Ex. 1st,  99)324123              2d,   99)547825
               3241                        5478
                 32                          54
             -------                     -------
             3273|96                     5533|57
   Quotient  3273 and rem. 96.                 1
                                         -------
                               Quotient 5533·58 rem.

              3d,  999)476523
                          476
                      -------
                      476|999
                        1
                      -------
             Quotient 477
```

To explain the reason of this, we must recollect, that whatever number of hundreds any dividend contains, it contains an equal number of 99's, together with an equal number of units. In Ex. 1, the dividend contains 3241 hundreds, and a remainder of 23. It therefore contains 3241 times 99, and also 3241, besides the remainder already mentioned.—Again, 3241 contains 32 hundreds and a remainder of 41. It therefore contains 32 99's, and also 32, besides the remainder of 41. Consequently the dividend contains 99, altogether, 3241 times and 32 times, that is, 3273 times, and the remainder consists of 23, 41, and 32, added, which make 96.

As multiplication supplies the place of frequent additions, and division of frequent subtractions, they are only repetitions and contractions of the simple rules; and, when compared together, their tendency is exactly opposite. As numbers, increased by addition, are diminished and brought back to their original quantity by subtraction; in like manner numbers compounded by multiplication are reduced by division to the parts from which they were compounded. The multiplier shows how many additions are necessary to produce the number; and the quotient shows how many subtractions are necessary to exhaust it. It follows that the product, divided by the multiplicand, will quote the multiplier; and because either factor may be assumed for the multiplicand, therefore the product divided by either factor quotes the other. It follows, also, that the dividend is equal to the product of the divisor and quotient multiplied together; and hence these operations mutually prove each other.

To prove multiplication: Divide the product by either factor. If the operation be right, the quotient is the other factor, and there is no remainder.

To prove division: Multiply the divisor and quotient together; to the product add the remainder, if any; and, if the operation be right, it makes up the dividend. Otherwise divide the dividend (after subtracting the remainder, if any) by the quotient. If the operation be right, it will quote the divisor. The reason of all those rules may be collected from the last paragraph.

Compound Division.

Rule I.—*When the dividend only consists of different denominations, divide the higher denomination, and reduce the remainder to the next lower, taking in* (p. 587, Reduction) *the given number of that denomination, and continue the division.*

             ----
```

It is best not to reduce the terms lower than is necessary to render them equal. For instance, if each of them consists of an even number of sixpences, fourpences, or the like, we reduce them to sixpences or fourpences, but not to pence.

The use of division is to find either of the factors by whose multiplication a given number is produced when the other factor is given, and therefore is of two kinds, since either the multiplier or the multiplicand may be

given. If the former be given, it discovers what that number is which is contained so many times in another. If the latter be given, it discovers how many times one number is contained in another. Thus, it answers the questions of an opposite kind to those mentioned under Rule V. p. 587, as, to find the quantity of a single parcel or share; to find the value, weight, or measure, of a single article; to find how much work is done, provisions consumed, interest incurred, or the like, in a single day, &c.

The last use of division is a kind of reduction exactly opposite to that described under Rule V. p. 587. The manner of conducting and arranging it, when there are several denominations in the question, will appear from the following examples.

1. To reduce 15783 pence to pounds, shillings, and pence.

```
          20
12)15783(1315(65
   12···  120·

Ans. 30 lb. 4 oz. 6 dwt. 1 gr.

In the first example we reduce 15783 pence to shillings, by dividing by 12, and obtain 1315 shillings, and a remainder of 3 pence. Then we reduce 1315 shillings to pounds by dividing by 20, and obtain 65 pounds and a remainder of 15 shillings. The divisions might have been contracted.

In the practice of arithmetic questions often occur which require both multiplication and division to resolve. This happens in reduction, when the higher denomination does not contain an exact number of the lower.

Rule for Mixed Reduction.—*Reduce the given denomination by multiplication to some lower one which is an aliquot part of both; then reduce that by division to the denomination required.*

Ex.—Reduce £31742 to guineas.

```
   31742
      20
   ─────
21)634840(30230
   63····
   ───
    048
     42
     ──
      64
      63
      ──
      10
```

Here we multiply by 20, which reduces the pounds to shillings, and divide the product by 21, which reduces the shillings to guineas.

Answer, 30230 guineas and 10 shillings.

Note 1. Guineas may be reduced to pounds by adding one twentieth part of the number.

2. Pounds may be reduced to merks by adding one half.

3. Merks may be reduced to pounds by subtracting one third.

Another case which requires both multiplication and division is, when the value, weight, measure, or duration of any quantity is given, and the value, &c. of a different quantity required, we first find the value, &c. of a single article by division, and then the value, &c. of the quantity required, by multiplication.

Ex. If 3 yards cost 15s. 9d. what will 7 yards cost at the same rate?

```
       s.  d.
3)     15  9 price of 3 yards.
        5  3 price of 1 yard.
           7
   ─────────
 £1    16  9 price of 7 yards.
```

Many other instances might be adduced where the operation and the reasons of it are equally obvious. These are generally, though unnecessarily, referred to the rule of proportion.

We shall now offer a general observation on all the operations in arithmetic. When a computation requires several steps, we obtain a just answer, whatever order we follow. Some arrangements may be preferable to others in point of ease, but all of them lead to the same conclusion. In addition or subtraction we may take the articles in any order, as is evident from the idea of number; or we may collect them into several sums, and add or subtract these either separately or together. When both the simple operations are required to be repeated, we may either complete one of them first, or may introduce them promiscuously; and the compound operations admit of the same variety. When several numbers are to be multiplied together, we may take the factors in any order, or we may arrange them into several classes, find the product of each class, and then multiply the products together. When a number is to be divided by several others we may take the divisors in any order, or we may multiply them into each other, and divide by the product; or we may multiply them into several parcels, and divide by the products successively. Lastly, When multiplication and division are both required, we may begin with either; and when both are repeatedly necessary, we may collect the multipliers into one product and the divisors into another, or we may collect them into parcels, or use them singly, and that in any order. Still we shall obtain the proper answer if none of the terms be neglected.

When both multiplication and division are necessary to obtain the answer of a question, it is generally best to begin with the multiplication, as this order keeps the account as clear as possible from fractions. The example last given may be wrought accordingly as follows:

```
     s.  d.
     15  9
         7
  ────────
3)5  10  3
  1  16  9
```

Some accountants prove the operations of arithmetic by a method which they call casting out the 9's, depending on the following principles:

1*st*, If several numbers be divided by any divisor (the remainders being always added to the next number), the sum of the quotients, and the last remainder, will be the same as those obtained when the sum of the number is divided by the same divisor. Thus, 19, 15, and 23, contain together as many 5's, as many 7's, &c. as their sum 57 does, and the remainders are the same; and, in this way, addition may be proven by division. It is from the correspondence of the remainders that the proof by casting out the 9's is deduced.

2*dly*, If any figure with ciphers annexed be divided by 9, the quotient consists entirely of that figure; and the remainder is also the same. Thus, 40 divided by 9 quotes 4, remainder 4; and 400 divided by 9 quotes 44, remainder 4. The same holds with all the digits, and the reason will be easily understood: every digit, with a ci-

pher annexed, contains exactly so many tens; it must therefore contain an equal number of 9's, besides a remainder of an equal number of units.

3dly, If any number be divided by 9, the remainder is equal to the sum of the figures of the number, or to the remainder obtained, when that sum is divided by 9. For instance, 3765 divided by 9 leaves a remainder of 3; and the sum of 3, 7, 6, and 5, is 21, which divided by 9 leaves a remainder of 3. The reason of this will appear from the following illustration:

3000	divided by 9 quotes	333,	remainder	3
700	9 quotes	77,	remainder	7
60	9 quotes	6,	remainder	6
5	9 quotes	0,	remainder	5
3765		416,	sum of rem.	21
Again: 21	divided by 9 quotes	2,	remainder	3;
wherefore, 3765	divided by 9 quotes	418,	remainder	3;

for the reason given. Hence we may collect the following rules for practice:

To cast the 9's out of any number, or to find what remainder will be left when any number is divided by 9: add the figures; and when the sum exceeds 9, add the figures which would express it. Pass by the 9's; and when the sum comes exactly to 9, neglect it, and begin anew. For example, if it be required to cast the 9's out of 3573294, we reckon thus; 3 and 5 are 8, and 7 is 15; 1 and 5 are 6, and 3 is 9, which we neglect; 2 and (passing by 9) 4 are 6; which is the remainder or Result. If the article out of which the 9's are to be cast contains more denominations than one, we cast the 9's out of the higher, and multiply the result by the value of the lower, and carry on the product (casting out the 9's, if necessary) to the lower.

To prove addition, cast the 9's out of the several articles, carrying the results to the following articles; cast them also out of the sum. If the operation be right, the results will agree.

To prove subtraction, cast the 9's out of the minuend; cast them also out of the subtrahend and remainder together; and if you obtain the same result, the operation is presumed right.

To prove multiplication, cast the 9's out of the multiplicand, and also out of the multiplier if above 9. Multiply the results together, and cast the 9's, if necessary, out of their product. Then cast the 9's out of the product, and observe if this result correspond with the former.

Ex. 1st, 9276 res. 6 $\times$ 8 = 48 res. 3.
8
74208 res. 3.

2d, 7898 res. 5 $\times$ 3 = 15 res. 6.
48 res. 3
63184
31592
379104 res. 6.

The reason of this will be evident, if we consider multiplication under the view of repeated addition. In the first example it is obviously the same. In the second, we may suppose the multiplicand repeated 48 times. If this be done, and the 9's cast out, the result, at the end of the 9th line, will be 0; for any number, repeated 9 times, and divided by 9, leaves no remainder. The same must happen at the end of the 18th, 27th, 36th, and 45th lines; and the last result will be the same as if the multiplicand had only been repeated 3 times. This is the reason for casting out the 9's from the multiplier as well as the multiplicand.

To prove division, cast the 9's out of the divisor, and also out of the quotient; multiply the results, and cast the 9's out of the product. If there be any remainder, add to it the result, casting out the 9's if necessary. If the account be right, the last result will agree with that obtained from the dividend.

Ex. 42) 2490 (59 res. 5 $\times$ 6 = 30 res. 3.
res. 6. 210
390
378
Rem. 12 - - - res. 3.
6

And the result of the dividend is 6.

This depends on the same reason as the last; for the dividend is equal to the product of the divisor and quotient added to the remainder.

We cannot recommend this method, as it lies under the following disadvantages.

1st, If an error of 9, or any of its multiples, be committed, the results will nevertheless agree; and so the error will remain undiscovered. And this will always be the case when a figure is placed or reckoned in a wrong column, which is one of the most frequent causes of error.

2dly, When it appears by the disagreement of the results that an error has been committed, the particular figure or figures in which the error lies are not pointed out, and consequently it is not easily corrected.

Chap. VI.—Rule of Proportion.

Sect. I.—Simple Proportion.

Quantities are reckoned proportional to each other when they are connected in such a manner, that if one of them be increased or diminished, the other increases or diminishes at the same time, and the degree of the alteration on each is a like part of its original measure. Thus, four numbers are in the same proportion, the first to the second as the third to the fourth, when the first contains the second, or any part of it, as often as the third contains the fourth, or the like part of it. In either of these cases, the quotient of the first divided by the second is equal to that of the third divided by the fourth; and this quotient may be called the *measure of the proportion.*

Proportionals are marked down in the following manner:

6 : 3 :: 8 : 4
12 : 36 :: 9 : 27
9 : 6 :: 24 : 16
16 : 24 :: 10 : 15

The rule of Proportion directs us, when three numbers are given, how to find a fourth, to which the third may have the same proportion that the first has to the second. It is sometimes called the *Rule of Three,* from the three numbers given; and sometimes the *Golden Rule,* from its various and extensive utility.

Rule. *Multiply the second and third terms together, and divide the product by the first.*

Ex. To find a fourth proportional to 18, 27, and 34.

18 : 27 :: 34 : 51
34
108
81
18)918(51
90
18
18

To explain the reason of this, we must observe, that if

two or more numbers be multiplied or divided alike, the products or quotients will have the same proportion.

18 : 27
Multiplied by 34, 612 : 918
Divided by 18, 34 : 51

The products 612, 918, and the quotients 34, 51, have therefore the same proportion to each other that 18 has to 27. In the course of this operation, the products of the first and third terms are divided by the first; therefore the quotient is equal to the third.

The first and second terms must always be of the same kind; that is, either both moneys, weights, measures, both abstract numbers, or the like. The fourth, or number sought, is of the same kind as the third.

When any of the terms is in more denominations than one, we may reduce them all to the lowest. But this is not always necessary. The first and second should not be reduced lower than directed, p. 589, col. 2, par. penult.; and when either the second or third is a simple number, the other, though in different denominations, may be multiplied without reduction.

```
             £   s.  d.
Ex. 5 : 7 :: 25  11  3
                     7        £   s.  d.
    ------------------
    5)  178  18  9      (35  15   9
```

The accountant must consider the nature of every question, and observe the circumstance which the proportion depends on; and common sense will direct him to this if the terms of the question be understood. It is evident that the value, weight, and measure of any commodity is proportioned to its quantity; that the amount of work or consumption is proportioned to the time; that gain, loss, or interest, when the rate and time are fixed, is proportioned to the capital sum from which it arises; and that the effect produced by any cause is proportioned to the extent of the cause. In these and many other cases the proportion is direct, and the number sought increases or diminishes along with the term from which it is derived.

In some questions, the number sought becomes less when the circumstances from which it is derived become greater. Thus, when the price of goods increases, the quantity which may be bought for a given sum is smaller; when the number of men employed at work is increased, the time in which they may complete it becomes shorter; and when the activity of any cause is increased, the quantity necessary to produce a given effect is diminished. In these and the like the proportion is said to be inverse.

General Rule for stating all questions, whether direct or inverse. *Place that number for the third term which signifies the same kind of thing with what is sought, and consider whether the number sought will be greater or less. If greater, place the least of the other terms for the first; but if less, place the greatest for the first.*

Ex. 1*st*, If 30 horses plough 12 acres, how many will 42 plough in the same time?

```
H.  H.  A
30 :: 42 :: 12 : answer.
```

Here, because the thing sought is a number of acres, we place 12, the given number of acres, for the third term; and because 42 horses will plough more than 30, we make the lesser number, 30, the first term, and the greater number, 42, the second term.

Ex. 2*d*, If 40 horses be maintained for a certain sum on hay, at 5d. per stone, how many will be maintained on the same sum when the price of hay rises to 8d.

```
d.  d.  H.
8 : 5 :: 40 : answer.
```

Here, because a number of horses is sought, we make the given number of horses, 40, the third term: and because fewer will be maintained for the same money when the price of hay is dearer, we make the greater price, 8d. the first term, and the lesser price, 5d. the second term.

The first of these examples is direct, the second inverse. Every question consists of a supposition and demand. In the first, the supposition is, that 30 *horses plough* 12 *acres*, and the demand, *how many* 42 *will plough;* and the first term of the proportion, 30, is found in the supposition, in this and every other direct question. In the second, the supposition is, that 40 *horses are maintained on hay at* 5d., and the demand, *how many will be maintained on hay at* 8d.? and the first term of the proportion, 8, is found in the demand, in this and every other inverse question.

When a proportion is stated, if the first and second terms, or first and third, be measured by the same number, we may divide them by that measure, and use the quotients in their stead.

Ex. If 36 yards cost 42 shillings, what will 27 cost?

```
Y.   Y.   sh.        Here 36 and 27 are both
36 : 27 :: 42        measured by 9, and we work
 4 :  3 :: 42        with the quotients 4 and 3.
           3
         ----  s.  d.
   4)126(31   6, the answer.
```

SECT. II.—COMPOUND PROPORTION.

Sometimes the proportion depends upon several circumstances. Thus, it may be asked, if 18 men consume 6 bolls of corn in 28 days, how much will 24 men consume in 56 days? Here the quantity required depends partly on the number of men, partly on the time; and the question may be resolved into the two following ones:

1*st*, If 18 men consume 6 bolls in a certain time, how many will 24 men consume in the same time?

```
M.   M.  B.  B.
18 : 24 : 6 : 8        Answer, 24 men will consume 8
      6                bolls in the same time.
    ----
18) 144(8
```

2*d*, If a certain number of men consume 8 bolls in 28 days, how many will they consume in 56 days?

```
D.   D.   B.  B.
28 : 56 :: 8 : 16      Ans. The same number of men
      8                will consume 16 bolls in 56 days.
    ----
28) 448(16
```

In the course of this operation, the original number of bolls, 6, is first multiplied into 24, then divided by 18, then multiplied into 56, then divided by 28. It would answer the same purpose to collect the multipliers into one product and the divisors into another, and then to multiply the given number of bolls by the former, and divide the product by the latter, p. 590, col. 2.

The above question may therefore be stated and wrought as follows:

```
Men  18  :  24 :: 6 bolls     Here we multiply 18 into
Days 28  :  56                28 for a divisor, and 6 into
    ----   ----               the product of 24 by 56 for
     144   144                a dividend.
     36    120
    ----   ----
     504   1344
              6
           ----
     504)8064(16, answer.
```

In general, state the several particulars on which the question depends, as so many simple proportions, attending to the sense of the question to discover whether the proportions should be stated directly or inversely; then multiply all the terms in the first rank together, and all

those in the second rank together, and work with the product as directed in the simple rule (Sect. i. p. 591.)

Ex. If 100 men make 3 miles of road in 27 days, in how many days will 150 men make 5 miles?

```
Men 150 : 100 :: 27 days.
      3     5
    ---   ---
    450   500
           27
          ---
450)13500(30 days, ans.
```

Here the first stating is inverse, because more men will do it in fewer days; but the second is direct, because more miles will require more days.

The following contraction is often useful. After stating the proportion, if the same number occurs in both ranks, dash it out from both; or, if any term in the first rank and another in the second rank are measured by the same number, dash out the original terms, and use the quotients in their stead.

Ex. If 18 men consume £30 value of corn in 9 months when the price is 16s. per boll, how many will consume £54 value in 6 months when the price is 12s. per boll? In this question the proportion depends upon three particulars—the value of corn, the time, and price; the first of which is direct, because the greater the value of provisions is, the more men are required to consume them; but the second and third are inverse, for the greater the time and price are, fewer men will consume an equal value.

$$
\begin{array}{lrcrl}
\text{Value} & \cancel{30} & : & \cancel{54} & :: 18 \text{ men.} \\
\text{Months} & \cancel{6} & : & \cancel{9} & \\
\text{Price} & \cancel{12} & : & \cancel{16} & \\
 & 10 & & 9 & \\
 & \cancel{3} & & \cancel{3} & \\
 & & & 4 & \\
\hline
 & & & 36 & \\
 & & & 18 & \\
\hline
 & & & 288 & \\
 & & & 36 & \\
\hline
 & \multicolumn{4}{l}{10)648(64\tfrac{8}{10}}
\end{array}
$$

Here we observe 6 in the first rank measures 54 in the second; so we dash them out, and place the quotient 9 in the second rank. Next, because 30 and 9 are both measured by 3, we dash them out, and place down the quotients 10 and 3; then, because 12 and 16 are both measured by 4, we dash them out and place down the quotients 3 and 4. Lastly, because there is now 3 in both columns, we dash them out, and work with the remaining terms, according to the rule.

The moneys, weights, and measures of different countries may be reduced from the proportion which they bear to each other.

Ex. If 112 lb. avoirdupois make 104 lb. of Holland, and 100 lb. of Holland make 89 of Geneva, and 110 of Geneva make 117 of Seville, how many lbs. of Seville will make 100lb. avoirdupois?

```
112 : 104 :: 100
100 :  89
110 : 117
```

If it be required how many lb. avoirdupois will make 100 of Seville, then the terms must be placed in the different columns thus,—

```
104 : 112 :: 100
 89 : 100
117 : 110
```

SECT. III.—DISTRIBUTIVE PROPORTION.

If it be required to divide a number into parts which have the same proportion to each other that several other given numbers have, we add these numbers together, and state the following proportion: As the sum is to the particular numbers, so is the number required to be divided to the several parts sought.

Ex. 1. Four partners engage to trade in company; A's stock is £150, B's £320, C's £350, D's £500, and they gain £730: Required how much belongs to each if the gain be divided among them in proportion to their stocks?

					Rem.
A's stock	£150	1320 . 150 :: 730 :	£ 82	19	1—120
B's	320	1320 : 320 :: 730 :	176	19	4—960
C's	350	1320 : 350 :: 730 :	193	11	2—720
D's	500	1320 : 500 :: 730 :	276	10	3—840
Whole stock	£1320		Proof £730		

This account is proved by adding the gains of the partners, the sum of which will be equal to the whole gain if the operation be right; but if there be remainders, they must be added, their sum divided by the common divisor, and the quotient carried to the lowest place.

Ex. 2. A bankrupt owes A £146, B £170, C £45, D £480, and E £72; his whole effects are only £342. 7s. 6d. How much should each have?

A's debt	£146	913 : 146 :: £342 7 6 :	£ 54	15		A's share.
B's	170	913 : 170 :: 342 7 6 :	63	15		B's
C's	45	913 : 45 :: 342 7 6 :	16	17	6	C's
D's	480	913 : 480 :: 342 7 6 :	180			D's
E's	72	913 : 72 :: 342 7 6 :	27			E's
	£913		£342	7	6	

This might also be calculated by finding what composition the bankrupt was able to pay per pound, which is obtained by dividing the amount of his effects by the amount of his debts, and comes to 7s. 6d., and then finding by the rules of practice how much each debt came to at that rate.

CHAP. VII.—RULES FOR PRACTICE.

The operations explained in the foregoing chapters comprehend the whole system of arithmetic, and are sufficient for every computation. In many cases, however, the work may be contracted by adverting to the particular circumstances of the question. We shall explain in this chapter the most useful methods which practice has suggested for rendering mercantile computations easy, in which the four elementary rules of arithmetic are sometimes jointly, sometimes separately employed.

SECT. I.—COMPUTATION OF PRICES.

The value of any number of articles, at a pound, a shilling, or a penny, is an equal number of pounds, shillings, or pence; and these two last are easily reduced to pounds. The value at any other rate may be calculated by easy methods, depending on some contraction already explained, or on one or more of the following principles.

1*st*, If the rate be an aliquot part of a pound, a shilling, or a penny, then an exact number of articles may be bought for a pound, a shilling, or a penny; and the value is found by dividing the given number accordingly. Thus, to find the price of so many yards at 2s. 6d., which is the eighth part of a pound, we divide the quantity by eight, because every eight yards cost £1.

2*d*, If the rate be equal to the sum of two other rates which are easily calculated, the value may be found by computing these separately, and adding the sums obtained. Thus, the price of so many yards at 9d. is found by adding their prices at 6d. and 3d. together.

3*d*, If the rate be equal to the difference of two easy rates, they may be calculated separately, and the lesser subtracted from the greater. Thus, the value of so many articles at 11d. is found by subtracting their value at a penny from their value at a shilling. We may suppose that a shilling was paid for each article, and then a penny returned on each.

4*th*, If the rate be a composite number, the value may be found by calculating what it comes to at one of the component parts, and multiplying the same by the other.

CASE I. *When the rate is an aliquot part of a pound, divide the quantity by the number which may be bought for a pound.*

Table of the aliquot parts of £1.

10 shillings	$=\frac{1}{2}$ of £1.	1s. 4d.	$=\frac{1}{15}$ of £1.
6s. 8d.	$=\frac{1}{3}$	1s. 3d.	$=\frac{1}{16}$
5s.	$=\frac{1}{4}$	1s.	$=\frac{1}{20}$
4s.	$=\frac{1}{5}$	8d.	$=\frac{1}{30}$
3s. 4d.	$=\frac{1}{6}$	6d.	$=\frac{1}{40}$
2s. 6d.	$=\frac{1}{8}$	4d.	$=\frac{1}{60}$
2s.	$=\frac{1}{10}$	3d.	$=\frac{1}{80}$
1s. 8d.	$=\frac{1}{12}$	2d.	$=\frac{1}{120}$

Ex. 1*st*,] What is the value of 7463 yards, at 4s.?

5)7463
£1492. 12s.

2*d*,] What is the value of 1773 yards, at 3d.?

8|0)1773
£22. 3s. 3d.

In the first example we divide by 5 because 4s. is $\frac{1}{5}$ of a pound; the quotient 1492 shows how many pounds they amount to; besides which there remain three yards at 4s., and these come to 12s. In the second example we divide by 80, as directed, and the quotient gives £22, and the remainder 13 yards, which at 3d. come to 3s. 3d.

This method can only be used in calculating for the particular prices specified in the table. The following six cases comprehend all possible rates, and will therefore exhibit different methods of solving the foregoing questions.

Case II. *When the rate consists of shillings only, multiply the quantity by the number of shillings, and divide the product by* 20: *Or, if the number of shillings be even, multiply by half the number, and divide the product by* 10.

Ex. 1*st*,] 4573 at 13s.

13
13719
4573
20)59449
£2972. 9s.

2*d*,] 7543 at 14s.

7
10)52801
£5280. 2s.

It is easy to perceive that the method in which the second example is wrought must give the same answer as if the quantity had been multiplied by 14 and divided by 20; and as the division by 10 doubles the last figure for shillings, and continues all the rest unchanged for pounds, we may obtain the answer at once, by doubling the right-hand figure of the product before we set it down.

If the rate be the sum of two or more aliquot parts of a pound, we may calculate these as directed in Case I. and add them. If it be any odd number of shillings, we may calculate for the even number next lower, and add thereto the value of a shilling. If it be 19s. we may subtract the value at a shilling from the value at a pound.

Case III. *When the rate consists of pence only.*

Method 1. If the rate be an aliquot part of a shilling, divide the quantity accordingly, which gives the answer in shillings; if not, it may be divided into two or more aliquot parts: calculate these separately, and add the values; reduce the answer to pounds.

1 penny is $\frac{1}{12}$ of a shilling.
2d. $\frac{1}{6}$ of ditto.
3d. $\frac{1}{4}$ of ditto.
4d. $\frac{1}{3}$ of ditto.
6d. $\frac{1}{2}$ of ditto.
5d. is the sum of 4d. and 1d. or of 2d. and 3d.
7d. is the sum of 4d. and 3d. or of 6d. and 1d.
8d. is the sum of 6d. and 2d. or the double of 4d.
9d. is the sum of 6d. and 3d.
10d. is the sum of 6d. and 4d.
11d. is the sum of 6d. 3d. and 2d.

Ex. 1*st*,] 7423 at 4d.

3)7423
20)2474 4
£123 14 4

Here, because 4d. is one third of a shilling, we divide by 3, which gives the price in shillings, and reduce these by division to pounds.

Ex. 2*d*,] 9786 at 9d.

At 6d. = $\frac{1}{2}$ of 1s. 4893
At 3d. = $\frac{1}{2}$ of 6d. 2446 6
At 9d. 7339 6
£366 19 6

Here we suppose first 6d. and then 3d. to be paid for each article; half the quantity is the number of shillings they would cost at 6d. each, half of that is the cost at 3d., and these added and reduced give the answer.

Ex. 3*d*,] 4856 at 11d.

At 6d. = $\frac{1}{2}$ of 1s. 2428
At 3d. = $\frac{1}{2}$ of 6d. 1214
At 2d. = $\frac{1}{3}$ of 6d. 809 4
11d. 4451 4
£222 11 4

Here we calculate what the articles would cost at 6d., at 3d., and at 2d., and add the values.

It is sometimes easier to calculate at two rates whose difference is the rate required, and subtract the lesser value from the greater. Thus, the last example may be wrought by subtracting the value at a penny from the value at a shilling. The remainder must be the value at 11d.

At 1s. 4856s.
At 1d. = $\frac{1}{12}$ 404 8
At 11d. 4451 4
£222 11 4

10d. may be wrought as the difference of 1s. and 2d.; and several other rates in like manner.

Method 2. Multiply the quantity by the number of pence, the product is the answer in pence. Reduce it to pounds.

Method 3. Find the value at a penny by division, and multiply the same by the number of pence.

Case IV. *When the rate consists of farthings only, find the value in pence, and reduce it by division to pounds.*

Ex. 1*st*,] 37843 at 1 farthing.

4)37843 farth.
12) 9460¾ pence
788 4¾
£39 8 4¾

3*d*, 72564 at ¾

3
4)217692 farth.
12) 54423 pence
4535 3
£226 15 3

2*d*,] 23754 at ½d.

2) 23754 halfpence
12) 11877 pence
989 9
£49 9 9

Or, 72564
At ½d. 36282 d.
At ¼d. 18141 d.
12) 54423
4535 3
£226 15 3

We may also find the amount in twopences, threepences, fourpences, or sixpences, by one division, and reduce these as directed in Case I.

Case V. *When the rate consists of pence and farthings, find the value of the pence, as directed in Case III., and that of the farthings from the proportion which they bear to the pounds. Add these together, and reduce.*

Ex. 1*st*,] 3287 at 5¼d.

At 4d.=$\frac{1}{3}$ of 1s. 1095 8
At 1d.=$\frac{1}{4}$ of 4d. 273 11
At 1f.=$\frac{1}{4}$ of 1d. 68 5¾
At 5¼ 1438 0¾
£71 18 0¾

Ex. 2*d*,] 4573 at 2¾

At 2d.=$\frac{1}{6}$ of 1s. 762 2
At ½d.=$\frac{1}{4}$ of 2d. 190 6½
At ¼d.=$\frac{1}{2}$ of ½d. 95 3¼
At 2¾ 1047 11¾
£52 7 11¾

Ex. 3*d*,] 2842 at 3¾

At 3d.=$\frac{1}{4}$ of 1s. 710 6
At 3f.=$\frac{1}{4}$ of 3d. 177 7½
At 3¾ 888 1½
£44 8 1½

Ex. 4*th*,] 3572 at 7½

At 6d. =$\frac{1}{2}$ of 1s. 1786
At 1½d.=$\frac{1}{4}$ of 6d. 446 6
At 7½ 2232 6
£111 12 6

Practice.

It is sometimes best to join some of the pence with the farthings in the calculation. Thus, in Ex. 4. we reckon the value at 6d. and at 3 halfpence, which makes 7½.

If the rate be 1½, which is an eighth part of a shilling, the value is found in shillings by dividing the quantity by 8.

CASE VI. *When the rate consists of shillings and lower denominations.*

Method 1. Multiply the quantity by the shillings, and find the value of the pence and farthings, if any, from the proportion they bear to the shillings. Add and reduce.

Ex. 1*st*, 4258 at 17s. 3d.

	17
	29806
	4258
17s.	72386
3d.=¼ of 1s.	1064 6
17s. 3d.	73450 6
	£3672 10 6

Ex. 2*d*, 5482 at 12s. 4½d.

	12
12s.	65784
3d. =¼ of 1s.	1370 6
1½d.=½ of 3d.	685 3
12s. 4½d.	67839 9
	£3391 19 9

Method 2. Divide the rate into aliquot parts of a pound; calculate the values corresponding to these, as directed in Case I., and add them.

Ex. 1*st*, 3894 at 17s. 6d.

10s. =½	£1947
5s. =¼	973 10
2s. 6d.=⅛	486 15
17s. 6d.	£3407 5

Ex. 2*d*, 1765 at 9s. 2d.

6s. 8d.=⅓	£588 6 8
2s. 6d.=⅛	220 12 6
9s. 2d.	£808 19 2

Sometimes part of the value is more readily obtained from a part already found; and sometimes it is easiest to calculate at a higher rate, and subtract the value at the difference.

Ex. 3*d*, 63790 at 5s. 4d.

4s. =⅕	£12758
1s. 4d.=⅓ of 4s.	4252 13 4
5s. 4d.	£17010 13 4

Ex. 4*th*, 3664 at 14s. 9d.

10s.=½	£1832
5s.=½ of 10s.	916
15s.	2748
3d.=$\frac{1}{20}$ of 5s.	45 16
14s. 9d.	£2702 4

Method 3. If the price contain a composite number of pence, we may multiply the value at a penny by the component parts.

Ex. 5628 at 2s. 11d. or 35d.

12)5628
20)469
£23 9
5
£117 5
7
£820 15

CASE VII. *When the rate consists of pounds and lower denominations.*

Method 1. Multiply by the pounds, and find the value of the other denominations from the proportion which they bear to the pounds.

Ex. 1*st*, 3592 at £3. 12s. 8d.

	3
£3	10776
12s. =⅕ of £3	2155 4
8d.=$\frac{1}{18}$ of 12s.	119 14 8
£3 12 8	£13050 18 8

Ex. 2*d*, 543 at £2. 5s. 10½d.

	2
£2	1086
5s. =¼ of £1	135 15
10d. =⅙ of 5s.	22 12 6
½d.=$\frac{1}{20}$ of 10d.	1 2 7½
£2 5 10½	£1245 10 1½

Practice.

Method 2. Reduce the pounds to shillings, and proceed as in Case VI.

Ex. 1*st*, 3592 at £3. 12s. 8d.

	72	20
	7184	72
	25144	
	258624	
4d.=⅓s.	1197 4	
4d.=⅓s.	1197 4	
8d.	261018 8	
	£13050 18 8	

Ex. 2d, 3683. at £2. 4s. 11d.

	45
	18415
	14732
At 45s.	165735
At 1d.=$\frac{1}{12}$s.	306 11
44s. 11d.	165428 1
	£8271 8 1

We have hitherto explained the various methods of computation when the quantity is a whole number and in one denomination. It remains to give the proper directions when the quantity contains a fraction, or is expressed in several denominations.

When the quantity contains a fraction, work for the integers by the preceding rules, and for the fraction take proportional parts.

When the quantity is expressed by several denominations, and the rate given for the higher, calculate the higher, consider the lower one as fractions, and work by the last rule.

When the rate is given for the lower denomination, reduce the higher denomination to the lower, and calculate accordingly.

Note 1. 7 lb. 14 lb. and 21 lb. are aliquot parts of 1 qr.; and 16 lb is $\frac{1}{7}$ of 1 cwt.; and are therefore easily calculated.

2. If the price of a dozen be so many shillings, that of an article is as many pence; and if the price of a gross be so many shillings, that of a dozen is as many pence.

3. If the price of a ton or score be so many pounds, that of 1 cwt., or a single article, is as many shillings.

4. Though a fraction less than a farthing is of no consequence, and may be rejected, the learner must be careful lest he lose more than a farthing, by rejecting several remainders in the same calculation.

SECT. II.—DEDUCTIONS ON WEIGHTS, &c.

The full weight of any merchandise, together with that of the cask, box, or other package, in which it is contained, is called the *gross weight*. From this we must make proper deductions in order to discover the quantity for which price or duty should be charged, which is called the *nett weight*.

Tare is the allowance for the weight of the package; and this should be ascertained by weighing it before the goods are packed. Sometimes, however, particularly in payment of duty, it is customary to allow so much per cwt. or so much per 100 lb. in place of tare.

Tret is an allowance of 4 lb. on 104 granted on currants and other goods on which there is waste, in order that the weight may answer when the goods are retailed.

Cloff or Draught is a further allowance granted on some goods in London of 2 lb. on every 3 cwt. to turn the scale in favour of the purchaser. The method of calculating these, and the like, will appear from the following examples.

Commission, &c.

Ex. 1*st*, What is the nett weight of 17 cwt. 2 q. 14 lb., tare 18 lb. per cwt.

```
                     Cwt. q. lb.            Cwt. q. lb.
                     17   2  14 gross, or   17   2  14
16 lb.=1/7 cwt.       2   2   2                      6
 2 lb.=1/8 of 16 lb.      1   7 1/4         105   3  –
18 lb.                2   3   9 1/4 tare              3
                                            317   1  –
                     14   3   4 3/4 nett.28)317 1/4 lb. Cwt. q. lb.
                                         4) 11  9 1/4(2  3  9 1/4 tare.
```

In the first method we add the tare at 16 lb., which is $\frac{1}{7}$ of the gross weight, to the tare at 2 lb., which is $\frac{1}{8}$ of the former. In the second we multiply the gross weight by 18; the tare is 1 lb. for each cwt. of the product, and is reduced by division to higher denominations.

Ex. 2*d*, What is the tret of 158 cwt. 3 q. 4 lb.

```
    Cwt. q. lb.  Cwt. q. lb.
26) 158  3  4  ( 6   0  12 tret.
    156
      2
      4
     11
     28
    312
    312
```

Because tret is always 4 lb. in 104, or 1 lb. in 26, it is obtained by dividing by 26.

3*d*, What is the cloff on 28 cwt. 2 q.?

```
   Cwt. q.
    28  2
        2
3)  57  (19 lb.
```

This allowance being 2 lb. on every 3 cwt., might be found by taking $\frac{1}{3}$ of the number of cwts. and multiplying it by 2. It is better to begin with multiplication, for the reason given, p. 590, col. 2, par. 2.

SECT. III.—COMMISSION, &c.

It is frequently required to calculate allowances on sums of money, at the rate of so much per £100. Of this kind is COMMISSION, or the allowance due to a factor for buying or selling goods, or transacting any other business; PREMIUM OF INSURANCE, or allowance given for engaging to repay one's losses at sea or otherwise; EXCHANGE, or the allowance necessary to be added or subtracted for reducing the money of one place to that of another; PREMIUMS ON STOCK, or the allowance given for any share of a public stock above the original value. All these, and others of a like kind, are calculated by the following

RULE.—*Multiply the sum by the rate, and divide the product by* 100. *If the rate contain a fraction, take proportional parts.*

Ex. What is the commission on £728 at 2¾ per cent.?

```
                 728
                   2
2 per cent.     1456
   1/2           364
   1/4           182
           1|00)20|02
                  20
                  40
                  12
                 4|80
                   4  Answ. £20  0  4 3/4
                 3|20
```

When the rate is given in guineas, as once common in cases of insurance, you may add a twentieth part to the sum before you calculate; or you may calculate at an equal number of pounds, and add a twentieth part to the answer.

When the given sum is an exact number of 10 pounds, the calculation may be done without setting down any figures. Every £10 at $\frac{1}{2}$ per cent. is a shilling, and at other rates in proportion. Thus, £170 at $\frac{1}{2}$ per cent. is 17s., and at $\frac{1}{4}$ per cent. 8s. 6d.

Interest.

SECT. IV.—INTEREST.

Interest is the allowance given for the use of money by the borrower to the lender. This is computed at so many pounds for each hundred lent for a year, and a like proportion for a greater or a less time. The highest rate is limited by our laws to 5 per cent. which is called the *legal interest*, and is due on all debts constituted by bond or bill, which are not paid at the proper term; and it is always understood when no other rate is mentioned.

The interest of any sum for a year, at any rate, is found by the method explained in the last section.

The interest of any number of pounds for a year at 5 per cent. is one twentieth part, or an equal number of shillings. Thus the interest of £34675 for a year is 34675 shillings.

The interest for a day is obtained by dividing the interest for a year by the number of days in a year. Thus the interest of £34675 for a day is found by dividing 34675 shillings by 365, and comes to 95 shillings.

The interest for any number of days is obtained by multiplying the daily interest by the number of days. Thus the interest of £34675 for 17 days is 17 times 95 shillings, or 1615 shillings; and this divided by 20, in order to reduce it, comes to £80. 15s.

It would have served the same purpose, and been easier, to multiply at first by 17, the number of days; and instead of dividing separately by 365, and by 20, to divide at once by 7300, the product of 365 multiplied by 20; and this division may be facilitated by the table inserted p. 589, col. 1.

The following practical rules may be inferred from the foregoing observations.

I. To calculate interest at 5 per cent.

Multiply the principal by the number of days, and divide the product by 7300.

II. To calculate interest at any other rate.

Find what it comes to at 5 per cent. and take a proper proportion of the same for the rate required.

Ex. 1*st*, Interest on £34675 for 17 days, at 5 per cent.

```
           34675
              17
          242725
          34675         £   s.
  73|00)5894|75(80  15
          584
            5475
              20
          1095|00
            73
            365
            365
              0
```

Ex. 2*d*, Interest on £304. 3s. 4d. for 8 days, at 4 per cent.

```
           £304   3   4
                      8     s.  d.

      584
        0
```

Interest at 5 per cent.	£0	6	8
Deduct $\frac{1}{5}$	0	1	4
Interest at 4 per cent.	£0	5	4

Chap. VIII.—Vulgar Fractions.

In order to understand the nature of vulgar fractions, we must suppose unity (or the number 1) divided into several equal parts. One or more of these parts is called a *fraction*, and is represented by placing one number in a small character above a line, and another under it: For example, two fifth parts is written thus, $\frac{2}{5}$. The number under the line (5) shows how many parts unity is divided into, and is called the *denominator*. The number above the line (2) shows how many of these parts are represented, and is called the *numerator*.

It follows, from the manner of representing fractions, that when the numerator is increased, the value of the fraction becomes greater; but when the denominator is increased, the value becomes less. Hence we may infer, that if the numerator and denominator be both increased, or both diminished, in the same proportion, the value is not altered; and therefore, if we multiply both by any number whatever, or divide them by any number which measures both, we shall obtain other fractions of equal value. Thus, every fraction may be expressed in a variety of forms, which have all the same signification.

A fraction annexed to an integer or whole number makes a mixed number; for example, five and two third parts, or $5\frac{2}{3}$. A fraction whose numerator is greater than its denominator is called an *improper fraction;* for example, seventeen third parts, or $\frac{17}{3}$. Fractions of this kind are greater than unity. Mixed numbers may be represented in the form of improper fractions, and improper fractions may be reduced to mixed numbers, and sometimes to integers. As fractions, whether proper or improper, may be represented in different forms, we must explain the method of reducing them from one form to another before we consider the other operations.

Problem I.—To reduce mixed numbers to improper fractions.

Multiply the integer by the denominator of the fraction, and to the product add the numerator. The sum is the numerator of the improper fraction sought, and is placed above the given denominator.

Ex. $5\frac{2}{3}=\frac{17}{3}$.

```
 5 integer.
 3 denominator.
15 product.
 2 numerator given.
17 numerator sought.
```

Because one is equal to two halves, or 3 third parts, or 4 quarters, and every integer is equal to twice as many halves, or four times as many quarters, and so on, therefore, every integer may be expressed in the form of an improper fraction, having an assigned denominator. The numerator is obtained by multiplying the integer into the denominator. Hence the reason of the foregoing rule is evident: 5 reduced to an improper fraction whose denominator is 3, makes $\frac{15}{3}$, and this added to $\frac{2}{3}$ amounts to $\frac{17}{3}$.

Problem II.—To reduce improper fractions to whole or mixed numbers,

Divide the numerator by the denominator.

Ex. $\frac{112}{17}=6\frac{10}{17}$.

```
17)112(6 10/17
   102
    10
```

This problem is the converse of the former, and the reason may be illustrated in the same manner.

Problem III.—To reduce fractions to lower terms.

Divide both numerator and denominator by any number which measures both, and place the quotients in the form of a fraction.

Example. $\frac{135}{360} = \frac{27}{72} = \frac{3}{8}$.

Here we observe that 135 and 360 are both measured by 5, and the quotients form $\frac{27}{72}$, which is a fraction of the same value as $\frac{135}{360}$ in lower terms. Again, 27 and 72 are both measured by 9, and the quotients form $\frac{3}{8}$, which is still of equal value, and in lower terms.

It is generally sufficient, in practice, to divide by such measures as are found to answer on inspection, or by the rules given p. 587, col. 2. But if it be required to reduce a fraction to the lowest possible terms, we must divide the numerator and denominator by the greatest number which measures both. What number this is may not be obvious, but will always be found by the following rule.

To find the greatest common measure of two numbers, divide the greater by the lesser and the divisor by the remainder continually till nothing remains; the last divisor is the greatest common measure.

Ex. Required the greatest number which measures 475 and 589?

```
475)589(1
    475
    114)475(4
        456
         19)114(6
            114
              0
```

Here we divide 589 by 475, and the remainder is 114; then we divide 475 by 114, and the remainder is 19; then we divide 114 by 19, and there is no remainder; from which we infer that 19, the last divisor, is the greatest common measure.

To explain the reason of this, we must observe, that any number which measures two others will also measure their sum and their difference, and will measure any multiple of either. In the foregoing example, any number which measures 589 and 475 will measure their difference, 114, and will measure 456, which is a multiple of 114; and any number which measures 475 and 456 will also measure their difference, 19. Consequently, no number greater than 19 can measure 589 and 475. Again, 19 will measure them both, for it measures 114, and therefore measures 456, which is a multiple of 114 and 475, which is just 19 more than 456; and because it measures 475 and 114, it will measure their sum, 589. To reduce $\frac{475}{589}$ to the lowest possible terms, we divide both numbers by 19, and it comes to $\frac{25}{31}$.

If there be no common measure greater than 1, the fraction is already in the lowest terms.

If the greatest common measure of 3 numbers be required, we find the greatest measure of the two first, and then the greatest measure of that number and the third. If there be more numbers, we proceed in the same manner.

Problem IV.—To reduce fractions to others of equal value that have the same denominator.

1st, *Multiply the numerator of each fraction by all the deno-*

minators except its own; the products are numerators to the respective fractions sought. 2d, *Multiply all the denominators into each other; the product is the common denominator.*

Ex. $\frac{4}{5}$ and $\frac{7}{9}$ and $\frac{3}{8} = \frac{288}{360}$ and $\frac{280}{360}$ and $\frac{135}{360}$.

$4 \times 9 \times 8 = 288$ first numerator.
$7 \times 5 \times 8 = 280$ second numerator.
$3 \times 5 \times 9 = 135$ third numerator.
$5 \times 9 \times 8 = 360$ common denominator.

Here we multiply 4, the numerator of the first fraction, by 9 and 8, the denominators of the two others; and the product, 288, is the numerator of the fraction sought, equivalent to the first. The other numerators are found in like manner, and the common denominator, 360, is obtained by multiplying the given denominators 5, 9, 8, into each other. In the course of the whole operation, the numerators and denominators of each fraction are multiplied by the same number, and therefore their value is not altered.

The fractions thus obtained may be reduced to lower terms, if the several numerators and denominator have a common measure greater than unity. Or, after arranging the number for multiplication, as is done above, if the same number occur in each rank, we may dash them out and neglect them; and if numbers which have a common measure occur in each, we may dash them out and use the quotients in their stead; or any number which is a multiple of all the given denominators may be used as a common denominator. Sometimes a number of this kind will occur on inspection, and the new numerators are found by multiplying the given ones by the common denominator, and dividing the products by the respective given denominators.

If the articles given for any operation be mixed numbers, they are reduced to improper fractions by Problem I. If the answer obtained be an improper fraction, it is reduced to a mixed number by Problem II. And it is convenient to reduce fractions to lower terms, when it can be done, by Problem III. which makes their value better apprehended, and facilitates any following operation. The reduction of fractions to the same denominator by Problem IV. is necessary to prepare them for addition or subtraction, but not for multiplication or division.

SECT. I.—ADDITION OF VULGAR FRACTIONS.

RULE.—*Reduce them, if necessary, to a common denominator; add the numerators, and place the sum above the denominator.*

Ex. 1*st*, $\frac{3}{5} + \frac{2}{9} = \frac{27}{45} + \frac{10}{45}$ by Problem IV. $= \frac{37}{45}$
2*d*, $\frac{5}{7} + \frac{8}{9} + \frac{9}{10} = \frac{450}{630} + \frac{560}{630} + \frac{567}{630} = \frac{1577}{630}$
by Problem II. $= 2\frac{317}{630}$.

The numerators of fractions that have the same denominator signify like parts; and the reason for adding them is equally obvious as that for adding shillings or any other inferior denomination.

Mixed numbers may be added by annexing the sum of the fractions to the sum of the integers. If the former be a mixed number, its integer is added to the other integers.

SECT. II.—SUBTRACTION OF VULGAR FRACTIONS.

RULE.—*Reduce the fractions to a common denominator; subtract the numerator of the subtrahend from the numerator of the minuend, and place the remainder above the denominator.*

Ex. Subtract $\frac{2}{7}$ from $\frac{5}{12}$ remainder $\frac{11}{84}$

$\left.\begin{array}{l} \frac{5}{12} = \frac{35}{84} \\ \frac{2}{7} = \frac{24}{84} \end{array}\right\}$ by Prob. IV.

from 35
take 24
remainder 11.

To subtract a fraction from an integer, subtract the numerator from the denominator, and place the remainder above the denominator; prefix to this the integer diminished by unity.

Ex. Subtract $\frac{3}{5}$ from 12. remainder $11\frac{2}{5}$.

To subtract mixed numbers, proceed with the fractions by the foregoing rule, and with the integers in the common method. If the numerator of the fraction in the subtrahend exceed that in the minuend, borrow the value of the denominator, and repay it by adding 1 to the unit place of the subtrahend.

Ex. Subtract $145\frac{7}{9}$ from $248\frac{3}{5}$

$\left.\begin{array}{l} \frac{3}{5} = \frac{27}{45} \\ \frac{7}{9} = \frac{35}{45} \end{array}\right\}$ by Prob. IV.

$$\begin{array}{r} 248\frac{27}{45} \\ 145\frac{35}{45} \\ \hline 102\frac{37}{45} \end{array}$$

Here, because 27, the numerator of the fraction in the minuend, is less than 35, the numerator of the subtrahend, we borrow 45, the denominator; 27 and 45 make 72, from which we subtract 35, and obtain 37 for the numerator of the fraction in the remainder; and we repay what was borrowed, by adding 1 to 5 in the unit place of the subtrahend.

The reason of the operations in adding or subtracting fractions will be fully understood if we place the numerators of the fractions in a column like a lower denomination, and add or subtract them as integers, carrying or borrowing according to the value of the high denomination.

SECT. III.—MULTIPLICATION OF VULGAR FRACTIONS.

RULE.—*Multiply the numerators of the factors together for the numerator of the product, and the denominators together for the denominator of the product.*

Ex. 1*st*, $\frac{2}{3} \times \frac{5}{7} = \frac{10}{21}$
$2 \times 5 = 10$ num.
$3 \times 7 = 21$ den.

2*d*, $8\frac{2}{5} \times 7\frac{3}{4} = \frac{1302}{20} = 65\frac{2}{20}$
$8\frac{2}{5} = \frac{42}{5}$ by Prob. I.
$7\frac{3}{4} = \frac{31}{4}$ by ditto
$42 \times 31 = 1302$
$5 \times 4 = 20$

To multiply $\frac{5}{7}$ by $\frac{2}{3}$ is the same as to find what two third parts of $\frac{5}{7}$ comes to. If one third part only had been required, it would have been obtained by multiplying the denominator 7 by 3, because the value of fractions is lessened when their denominators are increased: and this comes to $\frac{5}{21}$; and, because two thirds were required, we must double that fraction, which is done by multiplying the numerator by 2, and comes to $\frac{10}{21}$. Hence we infer that fractions of fractions, or compound fractions, such as $\frac{2}{7}$ of $\frac{3}{5}$, are reduced to simple ones by multiplication. The same method is followed when the compound fraction is expressed in three parts or more.

The foregoing rule extends to every case when there are fractions in either factor. For mixed numbers may be reduced to improper fractions, as is done in *Ex.* 2; and integers may be written, or understood to be written, in the form of fractions whose denominator is 1. It will be convenient, however, to give some further directions for proceeding when one of the factors is an integer, or when one or both are mixed numbers.

1*st*, To multiply an integer by a fraction, multiply it by the numerator, and divide the product by the denominator.

Ex. $3756 \times \frac{3}{5} = 2253\frac{3}{5}$

$$\begin{array}{l} 3756 \\ \quad 3 \\ \hline 5)11268(2253\frac{3}{5} \end{array}$$

2*d*, To multiply an integer by a mixed number, we multiply it first by the integer and then by the fraction, and add the products.

Ex. $138 \times 5\frac{3}{4} = 793\frac{1}{2}$

$138 \times 5 = 690$
$138 \times \frac{3}{4}$

$$\begin{array}{l} 138 \\ \quad 3 \\ \hline 4)414(\quad 103\frac{1}{2} \\ \qquad\qquad\;\; \overline{793\frac{1}{2}} \end{array}$$

Vulgar Fractions.

3*d*, To multiply a mixed number by a fraction, we may multiply the integer by the fraction, and the two fractions together, and add the products.

$$
\begin{array}{lll}
\textit{Ex.}\ 15\tfrac{3}{8} \times \tfrac{2}{9} = 3\tfrac{5}{12} & & \\
15 \times \tfrac{2}{9} = 3\tfrac{3}{9} & = 3\tfrac{4}{12} & \\
\tfrac{3}{8} \times \tfrac{2}{9} = \tfrac{6}{72} & = \underline{\tfrac{1}{12}} & \\
 & \ 3\tfrac{5}{12} &
\end{array}
$$

4*th*, When both factors are mixed numbers, we may multiply each part of the multiplicand, first by the integer of the multiplier, and then by the fraction, and add the four products.

$$
\begin{array}{lll}
\textit{Ex.}\ 8\tfrac{2}{5} \text{ by } 7\tfrac{3}{4} & & \\
8 \times 7 = & 56 & \\
8 \times \tfrac{3}{4} = \tfrac{24}{4} = & 6 & \text{by Prob. II.} \\
\tfrac{2}{5} \times 7 = \tfrac{14}{5} = 2\tfrac{4}{5} & 2\tfrac{16}{20} & \\
\tfrac{2}{5} \times \tfrac{3}{4} = & \underline{\tfrac{6}{20}} & \\
\text{product} & 65\tfrac{2}{20} & \text{as before.}
\end{array}
$$

SECT. IV.—DIVISION OF VULGAR FRACTIONS.

RULE I.—*Multiply the numerator of the dividend by the denominator of the divisor. The product is the numerator of the quotient.*

II.—*Multiply the denominator of the dividend by the numerator of the divisor. The product is the denominator of the quotient.*

Ex. Divide $\frac{2}{5}$ by $\frac{7}{9}$. quotient $\frac{18}{35}$.

$2 \times 9 = 18$

$5 \times 7 = 35.$

To explain the reason of this operation, let us suppose it required to divide $\frac{2}{5}$ by 7, or to take one seventh part of that fraction. This is obtained by multiplying the denominator by 7; for the value of fractions is diminished by increasing their denominators, and comes to $\frac{2}{35}$. Again, because $\frac{7}{9}$ is nine times less than seven, the quotient of any number divided by $\frac{7}{9}$ will be nine times greater than the quotient of the same number divided by 7. Therefore we multiply $\frac{2}{35}$ by 9, and obtain $\frac{18}{35}$.

If the divisor and dividend have the same denominator, it is sufficient to divide the numerators.

Ex. $\frac{12}{17}$ divided by $\frac{3}{17}$ quotes 4.

The foregoing rule may be extended to every case by reducing integers and mixed numbers to the form of improper fractions. We shall add some directions for shortening the operation when integers and mixed numbers are concerned.

1*st*, When the dividend is an integer, multiply it by the denominator of the divisor, and divide the product by the numerator.

Ex. Divide 368 by $\frac{5}{7}$

$$
\begin{array}{l}
\ \ \underline{\ \ \ 7\ \ } \\
5)2576(515\tfrac{1}{5} \text{ quotient.}
\end{array}
$$

2*d*, When the divisor is an integer, and the dividend a fraction, multiply the denominator by the divisor, and place the product under the numerator.

Ex. Divide $\frac{3}{8}$ by 5 quotient $\frac{3}{40}$

$8 \times 5 = 40$

3*d*, When the divisor is an integer, and the dividend a mixed number, divide the integer, and annex the fraction to the remainder; then reduce the mixed number thus formed to an improper fraction, and multiply its denominator by the divisor.

Ex. To divide $576\frac{4}{11}$ by 7 quotient $82\frac{26}{77}$

$$
\begin{array}{l}
7)\ 576\ (82 \\
\ \underline{56} \\
\ \ 16 \\
\ \ \underline{14} \\
\ \ \ 2\tfrac{4}{11} = \tfrac{26}{11} \\
11 \times 7 = 77
\end{array}
$$

Here we divide 576 by 7, the quotient is 82, and the remainder 2, to which we annex the fraction $\frac{4}{11}$, and reduce $2\frac{4}{11}$ to an improper fraction $\frac{26}{11}$, and multiply its denominator by 7, which gives $\frac{26}{77}$.

Hitherto we have considered the fractions as abstract numbers, and laid down the necessary rules accordingly. We now proceed to apply these to practice. Shillings and pence may be considered as fractions of pounds, and lower denominations of any kind as fractions of higher; and any operation, where different denominations occur, may be wrought by expressing the lower ones in the form of vulgar fractions, and proceeding by the previous rules. For this purpose the two following problems are necessary.

PROBLEM V.—To reduce lower denominations to fractions of higher.

Place the given number for the numerator, and the value of the higher for the denominator.

Examples.

1. Reduce 7d. to the fraction of a shilling. Ans. $\frac{7}{12}$.
2. Reduce 7d. to a fraction of a pound. Ans. $\frac{7}{240}$.
3. Reduce 15s. 7d. to a fraction of a pound. Ans. $\frac{187}{240}$.

PROBLEM VI.—To value fractions of higher denominations.

Multiply the numerator by the value of the given denomination, and divide the product by the denominator; if there be a remainder, multiply it by the value of the next denomination, and continue the division.

Ex. 1*st*, Required the value of $\frac{17}{60}$ of L1.

$$
\begin{array}{l}
17 \\
\underline{20}\quad\ \ \textit{s.}\quad \textit{d.} \\
60)340(5\quad 8 \\
\underline{300} \\
40 \\
\underline{12} \\
60)480 \\
\underline{480}
\end{array}
$$

2*d*, Required the value of $\frac{8}{9}$ of 1 cwt.

$$
\begin{array}{l}
8 \\
\underline{4}\quad \textit{qrs.}\ \ \textit{lb.} \\
9)32(\ 3\quad 15\tfrac{5}{9} \\
\underline{27} \\
5 \\
\underline{28} \\
9)140 \\
\underline{9} \\
50 \\
\underline{45} \\
5
\end{array}
$$

In the first example we multiply the numerator 17 by 20, the number of shillings in a pound, and divide the product, 340, by 60, the denominator of the fraction, and obtain a quotient of 5 shillings; then we multiply the remainder, 40, by 12, the number of pence in a shilling, which produces 480, which, divided by 60, quotes 8d. without a remainder. In the second example we proceed in the same manner; but as there is a remainder, the quotient is completed by a fraction.

Sometimes the value of the fraction does not amount to an unit of the lowest denomination; but it may be reduced to a fraction of that or any other denomination by multiplying the numerator according to the value of the places. Thus $\frac{1}{1289}$ of a pound is equal to $\frac{12}{1289}$ of a shilling, or $\frac{240}{1289}$ of a penny, or $\frac{960}{1289}$ of a farthing.

CHAP. IX.—DECIMAL FRACTIONS.

SECT. I.—NOTATION AND REDUCTION.

Decimal fractions are such as have 10, or some power of 10 (that is 100, 1000, &c.), for a denominator: such are these,—

$\frac{3}{10}$, $\frac{24}{100}$, $\frac{75}{1000}$, $\frac{462}{100000}$;

They are more simply written thus:

·3, ·24, ·075, ·00462;

the number of figures after the point being always the same as the number of ciphers in the denominators.

In decimal fractions, as thus written, the figure next

the point, to the right, indicates so many tenths; the next so many hundredths, and so on. Thus, in the fraction ·346, the figure 3 expresses 3 tenths, 4 denotes 4 hundredths, and 6, 6 thousandths.

The use of ciphers in decimals, as well as in integers, is to bring the significant figures to their proper places, on which their value depends. As ciphers, when placed on the left hand of an integer, have no signification, but, when placed on the right hand, increase the value ten times each; so ciphers, when placed on the right hand of a decimal, have no signification, but when placed on the left hand, diminish the value ten times each.

The notation and numeration of decimals will be obvious from the following examples:

4·7 signifies four, and seven tenth parts.
·47 four tenth parts, and seven hundredth parts, or 47 hundredth parts.
·047 four hundredth parts, and seven thousandth parts, or 47 thousandth parts.
·407 four tenth parts, and seven thousandth parts, or 407 thousandth parts.
4·07 four, and seven hundredth parts.
4·007 four, and seven thousandth parts.

To reduce vulgar fractions to decimal ones. *Annex a cipher to the numerator, and divide it by the denominator, annexing a cipher continually to the remainder.*

Ex. 1*st*, $\frac{12}{75}$=·16 2*d*, $\frac{5}{64}$=·078125 3*d*, $\frac{2}{3}$=·666

```
75)120(16     64)500(078125     3)20(666
   75            448               18
   ---           ---               --
   450            520               20
   450            512               18
   ---            ---               --
                   80                20
                   64                18
                   --                --
                   160               20
                   128
                   ---
                    320
                    320
```

4*th*, $\frac{5}{6}$=·833 5*th*, $\frac{7}{27}$=·259 6*th*, $\frac{7}{22}$=·3,18,18.

```
6)50(833     27)70(259     22)70(31818
  48            54            66
  --            --            --
   20           160            40
   18           135            22
   --           ---            --
    20           250           180
    18           243           176
    --           ---           ---
    20             7            40
                                22
                                --
                                18
```

The reason of this operation will be evident, if we consider that the numerator of a vulgar fraction is understood to be divided by the denominator; and this division is actually performed when it is reduced to a decimal.

In like manner, when there is a remainder left in division, we may extend the quotient to a decimal, instead of completing it by a vulgar fraction, as in the following example:

25)646(25$\frac{21}{25}$ or 25·84.

```
     50
     --
     146
     125
     ---
Rem. 21·0
     200
     ---
      100
      100
```

From the foregoing examples we may distinguish the several kinds of decimals. Some vulgar fractions may be reduced exactly to decimals, as Ex. 1*st* and 2*d*, and are called *terminate* or *finite decimals*. Others cannot be exactly reduced, because the division always leaves a remainder; but, by continuing the division, we will perceive how the decimal may be extended to any length. These are called interminate or *infinite decimals*. If the same figure continually returns, as in Ex. 3*d* and 4*th*, they are called *repeaters*. If two or more figures return in their order, they are called *circulates*. If this regular succession go on from the beginning, they are called *pure repeaters*, or *circulates*, as Ex. 3*d* and 5*th*. If otherwise, as Ex. 4*th* and 6*th*, they are mixed *repeaters* or *circulates*, and the figures prefixed to those in regular succession are called the *finite part*. Repeating figures are generally distinguished by a dash, and circulates by a comma or other mark, at the beginning and end of the circle; and the beginning of a repeater or circulate is pointed out in the division by an asterisk.

Lower denominations may be considered as fractions of higher ones, and reduced to decimals accordingly. We may proceed by the following rule, which is the same in effect as the former.

To reduce lower denominations to decimals of higher. *Annex a cipher to the lower denomination, and divide it by the value of the higher. When there are several denominations, begin at the lowest, and reduce them in their order.*

Ex. To reduce 5 cwt. 2 qr. 21 lb. to a decimal of a ton.

```
28)210(·75     4)2·75(·6875     20)5·6875(·284375
   196            24               40
   ---            --               --
   140             35              168
   140             32              160
   ---             --              ---
                    30              87
                    28              80
                    --              --
                     20              75
                     20              60
                     --              --
                                     150
                                     140
                                     ---
                                      100
                                      100
```

Here, in order to reduce 21 lb. to a decimal of 1 qr. we annex a cipher, and divide by 28, the value of 1 qr. This gives ·75. Then we reduce 2·75 qrs. to a decimal of 1 cwt. by dividing by 4, the value of 1 cwt., and it comes to ·6875. Lastly, 5·6875 cwt. is reduced to a decimal of a ton by dividing by 20, and comes to ·284375.

To value a decimal fraction. *Multiply it by the value of the denomination, and cut off as many decimal places from the product as there are in the multiplicand. The rest are integers of the lower denomination.*

Example. What is the value of ·425 of £1?

```
     ·425
       20
  -------
sh. 8·500
        6
  -------
 d. 3·000
```

SECT. II.—ARITHMETIC OF TERMINATE DECIMALS.

The value of decimal places decreases like that of integers, ten of the lower place in either being equal to one of the next higher; and the same holds in passing from integers to decimals. Therefore, all the operations are performed in the same way with decimals, whether placed by themselves or annexed to integers, as with pure integers. The only peculiarity lies in the arrangement and pointing of the decimals.

In addition and subtraction, *Arrange units under units, tenth parts under tenth parts, and proceed as in integers.*

Decimal Fractions.

32·035	from 13·348	and 12·248
116·374	take 9·2993	10·6752
160·63		
12·3645	4·0487	1·5728
321·4035		

In multiplication, *Allow as many decimal places in the product as there are in both factors. If the product has not so many places, supply them by prefixing ciphers on the left hand.*

Ex. 1*st*,	2*d*,	3*d*,
1·37	43·75	·1572
1·8	·48	·12
1096	35000	·018864
137	17500	
2·466	21·0000	

The reason of this rule may be explained, by observing, that the value of the product depends on the value of the factors; and since each decimal place in either factor diminishes its value ten times, it must equally diminish the value of the product.

To multiply decimals by 10, move the decimal point one place to the right; to multiply by 100, 1000, or the like, move it as many places to the right as there are ciphers in the multiplier.

In division, *Point the quotient so that there may be an equal number of decimal places in the dividend as in the divisor and quotient together.*

Therefore, if there be the same number of decimal places in the divisor and dividend, there will be none in the quotient.

If there be more in the dividend, the quotient will have as many as the dividend has more than the divisor.

If there be more in the divisor, we must annex (or suppose annexed) as many ciphers to the dividend as may complete the number in the divisor, and all the figures of the quotient are integers.

If the division leave a remainder, the quotient may be extended to more decimal places; but these are not regarded in fixing the decimal point.

The reason for fixing the decimal point as directed may be inferred from the rule followed in multiplication. The quotient multiplied by the divisor produces the dividend; and therefore the number of decimal places in the dividend is equal to those in the divisor and quotient together.

The first figure of the quotient is always at the same distance from the decimal point, and on the same side, as the figure of the dividend which stands above the unit place of the first product. This also takes place in integers; and the reason is the same in both.

Multiplication by fractions corresponds with division by integers, and division by fractions with multiplication by integers; when we multiply by $\frac{1}{2}$ or ·5, we obtain the same answer as when we divide by 2, and every integer has a correspondent decimal, which may be called its *reciprocal*. Multiplication by that decimal supplies the place of division by the integer, and division supplies the place of multiplication.

To find the reciprocal of any number, divide 1 with ciphers annexed by that number.

Ex. Required the reciprocal of 625.

625)1·000(·0016
625
3750
3750
0

The product of any number multiplied by ·0016 is the same as the quotient divided by 625.

Ex.	
625)9375(15	9375
625	·0016
3125	56250
3125	9375
0	15·0000

Because ·0016 is $\frac{1}{625}$ of unity, any number multiplied by that fraction will be diminished 625 times. For a like reason, the quotient of any number divided by ·0016 will be equal to the product of the same multiplied by 625.

Ex.	
·0016)516·0000(322500	516
48 · · · · ·	625
36	2580
32	1032
40	3096.
32	322500
80	
80

SECT. III.—APPROXIMATE DECIMALS.

It has been shown that some decimals, though extended to any length, are never complete; and others, which terminate at last, sometimes consist of so many places that it would be difficult in practice to extend them fully. In these cases, we may extend the decimal to three, four, or more places, according to the nature of the articles and the degree of accuracy required, and reject the rest of it as inconsiderable. In this manner we may perform any operation with ease by the common rules, and the answers we obtain are sufficiently exact for any purpose in business. Decimals thus restricted are called *approximates.*

Shillings, pence, and farthings, may be easily reduced to decimals of three places by the following rule: Take half the shillings for the first decimal place, and the number of farthings increased by one, if it amount to 24 or upwards; by two, if it amount to 48 or upwards; and by three, if it amount to 72 or upwards, for the two next places.

The reason of this is, that 20 shillings make a pound, two shillings is the tenth part of a pound, and therefore half the number of shillings makes the first decimal place. If there were 50 farthings in a shilling, or 1000 in a pound, the units of the farthings in the remainder would be thousandth parts, and the tens would be hundredth parts, and so would give the two next decimal places; but because there are only 48 farthings in a shilling, or 960 in a pound, every farthing is a little more than the thousandth part of a pound; and since 24 farthings make 25 thousandth parts, allowance is made for that excess by adding 1 for every 24 farthings, as directed.

If the number of farthings be 24, 48, or 72, and consequently the second and third decimal places 25, 50, and 75, they are exactly right; otherwise they are not quite complete, since there should be an allowance of $\frac{1}{24}$, not only for 24, 48, and 72 farthings, but for every other single farthing. They may be completed by the following rule: multiply the second and third decimal places, or their excess above 25, 50, 75, by 4. If the product amount to 24 or upwards, add 1; if 48, add 2; if 72, add 3. By this operation we obtain two decimal places more; and by continuing the same operation, we may extend the decimal till it terminate in 25, 50, 75, or in a repeater.

Decimals of sterling money of three places may easily be reduced to shillings, pence, and farthings, by the following rule: Double the first decimal place, and if the second be 5 or upwards, add 1 thereto for shillings. Then divide the second and third decimal places, or their excess above 50, by 4, first deducting 1, if it amount to 25

Decimal Fractions.

or upwards; the quotient is pence, and the remainder farthings.

As this rule is the converse of the former one, the reason of the one may be inferred from that of the other. The value obtained by it, unless the decimal terminate in 25, 50, or 75, is a little more than the true value; for there should be a deduction, not only of 1 for 25, but a little deduction of $\frac{1}{25}$ on the remaining figures of these places.

We proceed to give some examples of the arithmetic of approximates, and subjoin any necessary observations.

ADDITION.

Cwt.	*qrs.*	*lb.*	
3	2	14	= 3·625
2	3	22	= 2·94642
3	3	19	= 3·91964
4	1	25	= 4·47321
14	3	24	14·96427

SUBTRACTION.

Cwt.	*qrs.*	*lb.*	
3	2	2	= 3·51785
1	1	19	= 1·41964
2	–	11	2·09821

If we value the sum of the approximates, it will fall a little short of the sum of the articles, because the decimals are not complete.

It is proper to add 1 to the last decimal place of the approximate, when the following figure would have been 5 or upwards. Thus the full decimal of 3 qrs. 22 lb. is ·946,428571, and therefore ·94643 is nearer to it than ·946,42. Approximates thus regulated will give exacter answers, sometimes above the true one and sometimes below it.

The mark + signifies that the approximate is less than the exact decimal, or requires something to be added. The mark — signifies that it is greater, or requires something to be subtracted.

MULTIPLICATION.

```

```

Here the last four places are quite uncertain. The right-hand figure of each particular product is obtained by multiplying 8 into the figures of the multiplier; but if the multiplicand had been extended, the carriage from the right-hand place would have been taken in; consequently the right-hand place of each particular product, and the four places of the total product, which depend on these, are quite uncertain. Since part of the operation therefore is useless, we may omit it; and for this purpose it will be convenient to begin (as in p. 587, col. 1, *fifth* variety) at the highest place of the multiplier. We may perceive that all the figures on the right hand of the line in Meth. 2 serve no purpose, and may be left out if we only multiply the figures on the multiplicand, whose products are placed on the left hand of the line. This is readily done by inverting the multiplier in Meth. 3, and beginning each product with the multiplication of that figure which stands above the figure of the multiplier that produces it, and including the carriage from the right-hand place.

If both factors be approximates, there are at least as many uncertain places in the product as in the longest factor. If only one be an approximate, there are as many uncertain places as there are figures in that factor, and sometimes a place or two more, which might be affected by the carriage. Hence we may infer how far it is necessary to extend the approximates in order to obtain the requisite number of certain places in the product.

DIVISION.

```
·3724 —)798|64237 + (2144 or 3724)79864237(2144

           2167                      4
```

Here all the figures on the right hand of the line are uncertain, for the right-hand figure of the first product 7448 might be altered by the carriage if the divisor were extended; and all the remainders and dividuals that follow are thereby rendered uncertain. We may omit these useless figures, for which purpose we dash a figure on the right hand of the divisor at each step, and neglect it when we multiply by the figure of the quotient next obtained; but we include the carriage. The operation, and the reason of it, will appear clear, by comparing the operation at large, and contracted, in the above example.

CHAP. X.—INTERMINATE DECIMALS.

SECT. I.—REDUCTION OF INTERMINATE DECIMALS.

We have seen that some vulgar fractions admit of being converted into exact decimal fractions, while others have not that property, but proceed interminably, the numerator being either the same figure, or else a combination of figures always repeated. The fraction $\frac{3}{8}$ is of the first mentioned kind, its decimal value being $\frac{375}{1000}$, that is ·375; again, $\frac{1}{3}$=·333, &c. and $\frac{5}{7}$=·714285,714285, &c. are examples of the second kind. Let us suppose a fraction reduced to its lowest terms, $\frac{3}{8}$, for example. Now, to convert this into a decimal, we annex ciphers to the numerator (that is, we multiply it by some power of 10), and divide by the denominator, the decimal denominator being always that power of ten by which the numerator was multiplied. In the case of $\frac{3}{8}$, the numerator is multiplied by 1000, which is exactly divisible by 8; for when the numbers are expressed by the product of their simple factors, we have $1000=2\times2\times2\times5\times5\times5$ and $8=2\times2\times2$, and $\frac{1000}{8}=5\times5\times5=125$, therefore the decimal value of $\frac{3}{8}$ is $\frac{375}{1000}$, that is, ·375. Here it appears that the decimal fraction has a finite form, because the divisors of the denominator of the vulgar fraction are also divisors of a power of 10.

A like remark may be made concerning the fraction $\frac{7}{25}=\frac{7}{5\times5}$, the two equal divisors 5 being divisors of 10, and therefore their product a divisor of 100, and the fraction =·28.

In general, it appears that if the simple factors of the denominators of a vulgar fraction be all either 2 or 5, its decimal value will be finite, otherwise not.

The fraction $\frac{1}{9}$ is therefore, from its nature, incapable of being converted into a finite decimal; but this fraction, when converted into a decimal, being ·1111, &c. *ad infinitum*, therefore $\frac{2}{9}$ will be ·222, &c. and $\frac{3}{9}=\frac{1}{3}=$ ·333, &c. and so on to $\frac{8}{9}$, which will be ·888, &c. Hence it is manifest that every repeating decimal is equivalent to a vulgar fraction whose denominator is 9.

Again, since $\frac{1}{99}=$ ·010101, &c. *ad infinitum*, therefore $\frac{2}{99}=$ ·0202, &c.; and in like manner $\frac{17}{99}=$ ·1717, &c. and so on, from $\frac{1}{99}$ to $\frac{89}{99}$, which is equal to ·89,89,89, &c. Therefore every circulating decimal of two figures is convertible into a vulgar fraction whose denominator is 99.

And since $\frac{1}{999}=$ ·001001001, &c., therefore any fraction whose numerator consists of three figures, and deno-

Decimal Fractions.

minator 999, must produce a circulate of three figures; for example, $\frac{365}{999}=\cdot365365365$, &c.; and in like manner, since $\frac{1}{9999}=\cdot00010001$, &c., therefore every fraction whose numerator consists of not more than four figures, and which has 9999 for a denominator, must produce a circulate of four figures, and so on.

It is now sufficiently manifest that all circulating decimals may be generated from vulgar fractions whose denominators are formed by a repetition of the figure 9; and hence it follows that every circulate may be converted into a vulgar fraction of that form.

RULES for reducing interminate decimals to vulgar fractions.

I. *If the decimal be a pure repeater, place the repeating figure for the numerator, and 9 for the denominator.*

II. *If the decimal be a pure circulate, place the circulating figures for the numerator, and as many 9's as there are places in the circle for the denominator.*

III. *If there be ciphers prefixed to the repeating or circulating figures, annex a like number to the 9's in the denominator.*

IV. *If the decimal be mixed, subtract the finite part from the whole decimal. The remainder is the numerator, and the denominator consists of as many 9's as there are places in the circle, together with as many ciphers as there are finite places before the circle.*

Thus, $\cdot235{,}62=\frac{23327}{99000}$

From the whole decimal	23562
We subtract the finite part	235
and the remainder	23327 is the numerator.

The reason may be illustrated by dividing the decimal into two parts, whereof one is finite, and the other a pure repeater or circulate, with ciphers prefixed. The sum of the vulgar fractions corresponding to these will be the value of the decimal sought.

$\cdot235{,}62$ may be divided into $\cdot235=\frac{235}{1000}$ by Rule I.
and $\cdot000{,}62=\frac{62}{99000}$ by Rules II. III.

In order to add these vulgar fractions, we reduce them to a common denominator; and for that purpose we multiply both terms of the former by 99, which gives $\frac{23265}{99000}$; then we add the numerators.

235, or, by method explained p. 586, col. 1, par. 3,

		Sum of numerators.		
99				
2115	23500	23265	or	23562
2115	235	62		235
23265	23265	23327		23327

The value of circulating decimals is not altered though one or more places be separated from the circle and considered as a finite part, providing the circle be completed. For example, $\cdot27$ may be written $\cdot2{,}72$, $\frac{270}{990}$, or $\frac{27}{99}$, which is also the value of $\cdot27$; and if two or more circles be joined, the value of the decimal is still the same. Thus, $\cdot2727=\frac{2727}{9999}$, which is reduced by dividing the terms by 101 to $\frac{27}{99}$.

All circulating decimals may be reduced to a similar form, having a like number both of finite and circulating places. For this purpose, we extend the finite part of each as far as the longest, and then extend all the circles to so many places as may be a multiple of the number of places in each.

Ex. ·34,725, extended, ·34,725725725725
·1,4562, ·14,562456245624

Here the finite part of both is extended to two places, and the circle to 12 places, which is the least multiple for circles of 3 and 4 places.

SECT. II.—ADDITION AND SUBTRACTION OF INTERMINATE DECIMALS.

To add repeating decimals. *Extend the repeating figures one place beyond the longest finite ones, and when you add the right-hand column, carry to the next by 9.*

Ex.	$\cdot3752\dot{4}$	or	$\cdot3752\dot{4}$
	$\cdot\dot{8}$		$\cdot8888\dot{8}$
	·643		·643
	$\cdot7\dot{3}$		$\cdot7333\dot{3}$
			2·64046

To subtract repeating decimals. *Extend them as directed for addition, and borrow at the right-hand place, if necessary, by 9.*

Ex. 1*st*,	$\cdot9356\dot{6}$	*Ex.* 2*d*,	·646
	$\cdot8473\dot{8}$		$\cdot5342\dot{7}$
	$\cdot0882\dot{7}$		$\cdot1117\dot{2}$

The reason of these rules will be obvious, if we recollect that repeating figures signify ninth parts. If the right-hand figure of the sum or remainder be 0, the decimal obtained is finite; otherwise it is a repeater.

To add circulating decimals. *Extend them till they become similar* (p. 603, col. 1, par. *ult.* &c.); *and when you add the right-hand column, include the figure which would have been carried if the circle had been extended farther.*

Ex. 1*st*,	*Extended.*	*Ex.* 2*d*,	*Extended.*
·574,	·574,574,	·874,	·874,874874,
·2,698,	·269,869,	$\cdot146\dot{3}$	·146,333333,
·428	·428	·1,58,	·158,585858,
·37,983	·379,839,	·32,	·323,232323,
	1·652,284,		1·503,026390,

Note 1. Repeaters mixed with circulates are extended and added as circulates.

Note 2. Sometimes it is necessary to inspect two or more columns for ascertaining the carriage; because the carriage from a lower column will sometimes raise the sum of the higher, so as to alter the carriage from it to a new circle. This occurs in Ex. 2.

Note 3. The sum of the circles must be considered as a similar circle. If it consist entirely of ciphers, the amount is terminate. If all the figures be the same, the amount is a repeater. If they can be divided into parts exactly alike, the amount is a circle of fewer places; but, for the most part, the circle of the sum is similar to the extended circles.

To subtract circulating decimals. *Extend them till they become similar; and when you subtract the right-hand figure, consider whether* 1 *would have been borrowed if the circles had been extended farther, and make allowance accordingly.*

·5,72,	·974,	or ·974974,	·8,135,		or ·8,135135,
·4,86,	·86,	·868686,	·452907,		or ·4,529074,
·0,85,		·106288,			·3,606060,
					or ·3,60

SECT. III.—MULTIPLICATION OF INTERMINATE DECIMALS.

CASE I.—*When the multiplier is finite and the multiplicand repeats, carry by* 9 *when you multiply the repeating figure; the right-hand figure of each line of the product is a repeater, and they must be extended and added accordingly.*

Ex.	$\cdot1349\dot{4}$
	·367
	$9446\dot{1}$
	$80966\dot{6}$
	$404833\dot{3}$
	$\cdot0495246\dot{1}$

If the sum of the right-hand column be an even number of 9's, the product is finite; otherwise it is a repeater.

CASE II.—*When the multiplier is finite, and the multiplicand circulates, add to each product of the right-hand figure the carriage which would have been brought to it if the circle had been extended. Each line of the product is a circle similar to the multiplicand, and therefore they must be extended and added accordingly.*

The product is commonly a circulate similar to the

Decimal Fractions.

multiplicand; sometimes it circulates fewer places, repeats or becomes finite; it never circulates more places.

Ex. ·37,46, × ·235
·235
187,32,
1123,93,
7492,92,
·08804,19,

Case III.—*When the multiplier repeats or circulates, find the product as in infinite multipliers, and place under it the products which would have arisen from the repeating or circulating figures if extended.*

Ex. 1st, ·958 × ·$\dot{8}$
·8

·36,
4704
2352
28224|
282|24
2|8224
285,09,

It is evident, that if a repeating multiplier be extended to any length, the product arising from each figure will be the same as the first, and each will stand one place to the right hand of the former. In like manner, if a circulating multiplier be extended, the product arising from each circle will be alike, and will stand as many places to the right hand of the former as there are figures in the circle. In the foregoing examples there are as many of these products repeated as is necessary for finding the total product. If we place down more, or extend them farther, it will only give a continuation of the repeaters or circulates.

The multiplication of interminate decimals may be often facilitated by reducing the multiplier to a vulgar fraction, and proceeding as directed p. 598, col. 2, par 8. Thus,

3d, ·3824 × ·$\dot{7}$ = $\frac{7}{9}$
7
9)2·6768
·2974$\dot{2}$

4th, ·384 × ·23, = $\frac{23}{90}$
23 | 2
1152 | 23
768
90)8·832
·0981$\dot{3}$.

Therefore, in order to multiply by $\dot{3}$, we take one third part of the multiplier; and, to multiply by $\dot{6}$, we take two thirds of the same. Thus,

5th, ·784 × ·$\dot{3}$ = $\frac{1}{3}$
3)·784
·261$\dot{3}$

6th, ·8761 × ·$\dot{6}$ = $\frac{2}{3}$
2
3)1·7522
·5840$\dot{6}$

As the denominator of the vulgar fractions always consists of 8's or of 9's with ciphers annexed, we may use the contraction explained p. 589, col. 1, par 1, &c.; and this will lead us exactly to the same operation which was explained above, par. 1, &c., on the principles of decimal arithmetic.

7th, ·735 × ·326 = $\frac{323}{990}$
323 | 3

In *Ex.* 12 we have omitted the products of the divisor, and only marked down the remainders. These are found

Decimal Fractions.

by adding the left-hand figure of the dividual to the remaining figures of the same. Thus, 363 is the first dividual, and 3, the left hand figure, added to 63, the remaining figures, gives 66 for the first remainder; and the second dividual, 666, is completed by annexing the circulating figure 6, the reason of which may be explained as follows. The highest place of each dividual shows, in this example, how many hundreds it contains; and as it must contain an equal number of ninety-nines, and also an equal number of units, it follows that these units, added to the lower places, must show how far the dividual exceeds that number of ninety-nines. The figure of the quotient is generally the same as the first place of the dividual, sometimes one more. This happens in the last step of the foregoing example, and is discovered when the remainder found, as here directed, would amount to 99 or upwards; and the excess above 99 only must in that case be taken to complete the next dividual.

14*th*, ·01, × ·01, $= \frac{1}{99}$

1

99)·01(·000102030405060708091011121314151617181920

The number of places in the circle of the product is sometimes very great, though there be few places in the factors; but it never exceeds the product of the denominator of the multiplier, multiplied by the number of places in the circle of the multiplicand. Therefore, if the multiplier be $\dot{3}$ or $\dot{6}$, the product may circulate three times as many places as the multiplicand; if the multiplier be any other repeater, nine times as many; if the multiplier be a circulate of two places, ninety-nine times as many: thus, in the last example, ·01, a circulate of two places, multiplied by ·01, a circulate of two places, produces a circulate of twice 99, or 198 places. And the reason of this limit may be inferred from the nature of the operation; for the greatest possible number of remainders, including 0, is equal to the divisor 99; and each remainder may afford two dividuals, if both the circulating figures, 3 and 6, occur to be annexed to it. If the multiplier circulate three places, the circle of the product, for a like reason, may extend 999 times as far as that of the multiplicand. But the number of places is often much less.

SECT. IV.—DIVISION OF INTERMINATE DECIMALS.

CASE I.—*When the dividend only is interminate, proceed as in common arithmetic; but when the figures of the dividend are exhausted, annex the repeating figure, or the circulating figures in their order, instead of ciphers, to the remainder.*

Ex. 1*st*, Divide ·5326 by ·7

3*d*, Divide ·6532$\dot{8}$ by 8.

8)·6532$\dot{8}$(·08166$\dot{1}$.

In these accounts the quotient is never finite. It may repeat if the dividend repeat; or, if the dividend circulate, it may circulate an equal number of places, often more, and never fewer. The greatest possible extent of the circle is found by multiplying the divisor into the number of places in the circle of the dividend. Thus, a circulate of 3 places, divided by 3, quotes a circulate of 3 times 3 or 9 places.

CASE II.—*When the divisor is interminate, the multiplications and subtractions must be performed according to the directions given for repeating and circulating decimals.*

Ex. 1*st*, Divide ·37845 by $\dot{5}$.

$\dot{5}$) ·37845(·68121

1090,90
0

The foregoing method is the only one which properly depends on the principles of decimal arithmetic; but it is generally shorter to proceed by the following rule.

Reduce the divisor to a vulgar fraction, multiply the dividend by the denominator, and divide the product by the numerator.

Ex. 1*st*, Divide ·37845 by $\dot{6} = \frac{5}{9}$.

9

5)3·40605(·68121.

2*d*, Divide ·3784$\dot{6}$ by $\dot{6} = \frac{2}{3}$

3

2)1·1353$\dot{6}$(·56768$\dot{3}$.

Note 1. Division by $\dot{3}$ triples the dividend, and division by $\dot{6}$ increases the dividend one half.

Note 2. When the divisor circulates, the denominator of the vulgar fraction consists of 9's, and the multiplication is sooner performed by the contraction explained p. 586, col. 1. It may be wrought in the same way when the divisor repeats, and the denominator of consequence is 9.

Note 3. If a repeating dividend be divided by a repeating or circulating divisor; or, if a circulating dividend be divided by a similar circulating divisor; or, if the number of places in the circle of the divisor be a multiple of the number in the dividend; then the product of the dividend multiplied by the denominator of the divisor will be terminate, since like figures are subtracted from like in the contracted multiplication, and consequently no remainder left.

Note 4. In other cases the original and multiplied dividend are similar, and the form of the quotient is the same as in the case of a finite divisor.

Note 5. If the terms be similar, or extended till they become so, the quotient is the same as if they were finite, and the operation may be conducted accordingly; for the quotient of vulgar fractions that have the same denominator is equal to the quotient of their numerators.

Chap. XI.—Of the Extraction of Roots.

The origin of powers of involution has already been explained under the article Algebra. There now remains, therefore, only to give the most expeditious methods of extracting the square and cube roots; the reasons of which will readily appear from what is said under that article. As for all powers above the cube, unless such as are multiples of either the square or cube, the extraction of their roots admits of no deviation from the algebraic canon, which must be always constructed on purpose for them.

If the root of any power not exceeding the seventh power be a single digit, it may be obtained by inspection from the following Table of powers.

1st power or root.	2d power or square.	3d power or cube.	4th power or biquadrate.	5th power or sursolid.	6th power or cube squared.	7th power.
1	1	1	1	1	1	1

8	64	512	4096	32768	262144	2097152
9	81	729	6561	59049	531441	4782969

Sect. I.—Extraction of the Square Root.

Rule I.—*Divide the given number into periods of two figures, beginning at the right hand in integers, and pointing toward the left. But in decimals begin at the place of hundreds, and point toward the right. Every period will give one figure in the root.*

II.—*Find by the table of powers, or by trial, the nearest lesser root of the left-hand period; place the figure so found in the quot; subtract its square from the said period, and to the remainder bring down the next period for a dividual or resolvend.*

III.—*Double the quot for the first part of the divisor; inquire how often this first part is contained in the whole resolvend, excluding the unit's place; and place the figure denoting the answer both in the quot and on the right of the first part; and you have the divisor complete.*

IV.—*Multiply the divisor, thus completed, by the figure put in the quot, subtract the product from the resolvend, and to the remainder bring down the following period for a new resolvend, and then proceed as before.*

Note 1*st*, If the first part of the divisor, with unity supposed to be annexed to it, happen to be greater than the resolvend, in this case place 0 in the quot, and also on the right of the partial divisor; to the resolvend bring down another period; and proceed to divide as before.

Note 2*d*, If the product of the quotient figure into the divisor happen to be greater than the resolvend, you must go back and give a lesser figure to the quot.

Note 3*d*, If, after every period of the given number is brought down, there happen at last to be a remainder, you may continue the operation by annexing periods, or pairs of ciphers, till there be no remainder, or till the decimal part of the quot repeat or circulate, or till you think proper to limit it.

After getting half of the decimal places, work by contracted division for the other half; and obtain them with the same accuracy as if the work had been at large.

3*d*, Required the square root of ·2916.

·2916(·54 root.
25
104)416
416

If the square root of a vulgar fraction be required, find the root of the given numerator for a new numerator, and find the root of the given denominator for a new denominator. Thus the square root of $\frac{4}{9}$ is $\frac{2}{3}$, and the root of $\frac{16}{25}$ is $\frac{4}{5}$; and thus the root of $\frac{25}{4}$ ($= 6\frac{1}{4}$) is $\frac{5}{2} = 2\frac{1}{2}$.

But if the root of either the numerator or denominator cannot be extracted without a remainder, reduce the vulgar fraction to a decimal, and then extract the root, as in Ex. 3*d*, above.

Sect. II.—Extraction of the Cube Root.

Rule I.—*Divide the given number into periods of three figures, beginning at the right hand in integers, and pointing toward the left. But in decimals, begin at the place of thousands, and point toward the right. The number of periods shows the number of figures in the root.*

II.—*Find by the table of powers, or by trial, the nearest lesser root of the left-hand period; place the figure so found in the quot; subtract its cube from the said period; and to the remainder bring down the next period for a dividual or resolvend.*

The divisor consists of three parts, which may be found as follows:

III. *The first part of the divisor is found thus: Multiply the square of the quot by 3, and to the product annex two ciphers; then inquire how often this first part of the divisor is contained in the resolvend, and place the figure denoting the answer in the quot.*

IV. *Multiply the former quot by 3, and the product by the figure now put in the quot; to this last product annex a cipher, and you have the second part of the divisor. Again, square the figure now put in the quot for the third part of the divisor; place these three parts under one another as in addition, and their sum will be the divisor complete.*

V. *Multiply the divisor thus completed by the figure last put in the quot, subtract the product from the resolvend, and to the remainder bring down the following period for a new resolvend, and then proceed as before.*

Note 1. If the first part of the divisor happen to be equal to or greater than the resolvend, in this case place 0 in the quot, annex two ciphers to the said first part of the divisor, to the resolvend bring down another period, and proceed to divide as before.

Note 2. If the product of the quotient figure into the divisor happen to be greater than the resolvend, you must go back, and give a lesser figure to the quot.

Note 3. If, after every period of the given number is brought down, there happen at last to be a remainder, you may continue the operation by annexing periods of three ciphers till there be no remainder, or till you have as many decimal places in the root as you judge necessary.

If the cube root of a vulgar fraction be required, find the cube root of the given numerator for a new numerator, and the cube root of the given denominator for a new denominator. But if the root of either cannot be extracted without a remainder, reduce the vulgar fraction to a decimal, and then extract the root.

ARIUS, a presbyter of the church of Alexandria, celebrated as having given his name to the most extensive and formidable heresy that ever divided the Christian Church. He is supposed to have been a native of Libya, the country which gave birth in the previous century to Sabellius, the heresiarch whose doctrine represented the opposite pole to that of Arius.

It had more than once been decided by the voice of the church, in opposition to Sabellius and other heretics, that there are three distinct persons in the Divine Trinity. But the mutual relation, and the nature of the difference between these persons, had not yet formed a subject of dispute or of decision, and various opinions were held regarding it, without its being considered necessary that a distinct and precise phraseology should be adopted on a point so difficult and mysterious.

It was in the learned and disputatious city of Alexandria that the matter first came to an open controversy. Alexander, the Christian bishop of that city, maintained in an assembly of his presbyters, that the Son of God is not only equal to the Father, but of the same essence (ὁμοούσιος). Arius, who is represented as a man of great learning and eloquence, and of high reputation for sanctity and zeal, opposed his bishop, on the ground that his doctrine was a relapse into the error of Sabellius, and going to the opposite extreme, maintained that the Son was not *the same* in substance with the Father, but only *similar* (ὁμοιούσιος), and that, though the highest of all creatures, there was a time when he was not.

The opinions of Arius found many supporters, the most distinguished and influential of whom was Eusebius, bishop of Nicomedia, who, being a favourite of Constantia the sister of the emperor, secured for Arius important patronage. Alexander having failed in his attempt to extinguish the heresy by warning and remonstrance, called a council of African bishops at Alexandria (A.D. 321), which condemned the Arian doctrine as blasphemous, and cast the offender out of the church. The heresy, however, continued to spread. The Emperor Constantine, who at first treated the matter as a trifling logomachy, at length found it necessary for the peace of the church to call a general council at the city of Nicæa, in Bithynia, A.D. 325. At this celebrated assembly, composed of 318 bishops from all parts of the Christian world, the doctrine of the *consubstantiality* of the Son with the Father was, after much discussion, decreed as the orthodox faith of the church, and embodied in a definite formula, which not merely expressed the catholic faith but specially anathematized the Arian doctrine and its supporters as accursed. Arius was banished to Illyricum, his books were ordered to be burned, and capital punishment was denounced against all who should keep them in their possession.

But the heresy was not thus to be extinguished. Arius had powerful friends at court, and his party, though branded with the condemnation of the church, made continual progress. After five years' banishment he was recalled to Constantinople, where he satisfied the unsettled theological judgment of the emperor by a confession of faith so vaguely worded that, without abjuring his own opinions, he seemed

to consent to the orthodox faith. Athanasius, bishop of Alexandria, was now commanded to receive Arius and his followers into communion with the church; and indomitably resisting the imperial mandate, and the attacks of the Arian party, was, by their influence, deprived of his bishopric, and banished to Treves. A day was now fixed by the Emperor for the solemn reception of Arius into communion with the church, but on his way through the streets of Constantinople to the scene of his triumph, Arius suddenly died, in a manner which his friends regarded as the effect of poison, and his enemies as the judgment of God in answer to the prayers of their faithful bishop Alexander. It is unnecessary to say that neither theory is capable of proof. The heresy, however, did not expire with the heresiarch; his party continued still in great credit at court. Athanasius, indeed, was soon recalled from banishment, but as soon removed again; for the Arians, under the countenance of government, made and deposed bishops as it best served their purposes. In short, this heresy flourished for more than 300 years. It was the reigning religion of Spain for above two centuries: it was on the throne both in the East and West; it prevailed among the Goths, the Vandals, the Burgundians, and the Alani, and did not disappear till about the end of the eighth century. It was afterwards set on foot in the West by Servetus. Erasmus was accused of attempting to revive it in his Commentaries on the New Testament, and the great names of Grotius and Milton are claimed by its defenders. In modern times, Arianism, as a distinctive term, has been merged in that of *Unitarianism;* q.v.—See Mosheim and Neander's *Church Histories;* Burton *On the Early Heresies, &c.;* Bull's *Defence of the Nicene Faith;* and Gibbon's *History of Rome.*

ARK, Noah's, a floating vessel built by the patriarch Noah, for the preservation of his family, and the several species of animals, during the Deluge. The ark has afforded several points of curious inquiry relating to its form, capacity, materials, &c. The wood of which it was built is called in the Hebrew *gopher wood*, and in the Septuagint *square timbers.* Some translate the original *cedar*, others *pine*, others *box*, &c. Pelletier prefers cedar, on account of its incorruptibility and the great abundance of it in Asia. Fuller and Bochart contend that it was built of what the Greeks call *κυπαρισσός*, or the *cypress tree;* for, taking away the termination, *kupar* and *gopher* differ very little in sound. In what place Noah built and finished his ark is no less a matter of dispute; but the most general opinion is, that it was built in Chaldea, in the territories of Babylon. Its dimensions, as given by Moses, are 300 cubits in length, 50 in breadth, and 30 in height. Dr Arbuthnot computes its burthen at 81,062 tons. It contained, besides eight persons of Noah's family, one pair of every species of unclean animals, and seven pairs of every species of clean animals, with provisions for them all during the whole year. The insuperable difficulties connected with the belief that all the existing species of animals were provided for in the ark, are obviated by adopting the suggestion of Bishop Stillingfleet, approved by Matthew Poole, Pye Smith, Le Clerc, Rossenmüller, and others, that the Deluge did not extend beyond that region of the earth then inhabited, and that only the animals of that region were preserved in the Ark. See Deluge, and Kitto's *Biblical Cyclopædia.*

Ark of the Covenant, a kind of chest, of an oblong shape, made of shittim (acacia) wood, a cubit and a half broad and high, two cubits long, and covered on all sides with the purest gold. It was ornamented on its upper surface with a border of gold; and on each of the two sides were two gold rings, in which were placed the gold-covered poles by which it was carried. The lid or cover of the ark was made of the purest gold Over it, at the two extremities, were two cherubim, with their faces turned towards each other, and inclined a little towards the lid (or *mercy-seat*); and their wings spread out over the top of the ark.

This sacred object was deposited in the innermost part of the tabernacle, called "the holy of holies," and afterwards in the corresponding apartment of the Temple. Within it were deposited the tables of the law; beside it were preserved a golden pot full of manna, the rod of Aaron, and a copy of the book of the law.

Extreme sanctity attached to the ark, as the material symbol of the Divine presence. During the marches of the Israelites it was covered with a purple pall, and borne by the priests, with great reverence and care, in advance of the host. It is not wonderful therefore that the neighbouring idolaters looked upon it as the God of the Israelites (1 Sam. iv. 6, 7), a delusion which may have been strengthened by the figures of the cherubim on it. After the settlement of the Jews in Palestine, the ark remained in the tabernacle at Shiloh until the time of Eli, when it was carried along with the army in the war against the Philistines, under the superstitious notion that it would secure the victory to the Hebrews. Not only however were they beaten, but the ark itself was taken by the Philistines (1 Sam. iv. 3–11), whose triumph was, however, very short lived, as they were so oppressed by the hand of God, that after seven months they were glad to send it back again. After that it remained apart from the tabernacle at Kirjath-jearim, where it continued until the time of David, who succeeded in effecting its safe removal, in grand procession, to Mount Zion (2 Sam. vi.) When the Temple of Solomon was completed, the ark was deposited in the sanctuary (1 Kings viii. 6–9). What became of it when the Temple was plundered and destroyed by the Babylonians is not known. The Jews believe that it was concealed from the spoilers, and account it among the hidden things which the Messiah is to reveal. It is certain, however, from the consent of all the Jewish writers, that the old ark was not contained in the second temple, and there is no evidence that any new one was made. Indeed the absence of the ark is one of the important particulars in which this temple was held to be inferior to that of Solomon.—See Calmet's *Dissertation sur l'Arche d'Alliance.*

ARKANSAS, one of the United States of North America, lying between Lat. 33. and 36. 30. N., and Long. 89. 30. and 94. 30. W. It is bounded as follows:—North by the state of Missouri, east by the Mississippi River, south by Louisiana, west by Texas and the Indian territory. Area 52,198 square miles. Population in 1840, 97,574; and in 1850, 209,639, of whom 46,982 were slaves. The surface of Arkansas is extremely diversified, and the soil of very unequal quality, though a large proportion of it is rich and fertile. The parts bordering on the Mississippi are low, and frequently inundated: the western portion is mountainous, being traversed by the Ozarks, which attain a general altitude of 2000 feet. Its principal rivers, besides the Mississippi, are the Arkansas, the St Francis, the White River, the Ouachita or Washita, and the Red River. The climate, except in the low lands, is generally salubrious. In the north-western parts, however, the winters are severe, with much snow, and piercing north winds.

The mineral wealth of this state is greater than that of any other east of the Rocky Mountains: coal in great variety (including anthracite) and iron are most abundant; lead, zinc, manganese, gypsum, marble, and rock-salt, are plentiful; and silver and gold are found. Agriculture has hitherto been the chief pursuit of the inhabitants, who raise large quantities of cotton, maize, wheat, oats, tobacco, hemp, flax, sugar, &c. In 1850, the cotton crop amounted to 2,599,480 lb.; maize to 8,857,296 bushels; tobacco to 224,164 lb.; butter to 1,854,104 lb. The preparation of staple commodities, and various articles for home consumption, form the chief manufactures.

In 1819, Arkansas, which had previously formed a part of

the Missouri territory, became a separate territorial government; and in 1836 it was admitted into the Union as an independent state. The people have the election of the governor, who continues in office for four years; and the legislature is conducted by a senate and a house of representatives. Little Rock is the seat of government. The judiciary consists of a supreme court, with a chief-justice and two associate justices, and six circuit-courts. The judges of the supreme court are chosen by the legislature, and hold office for eight years: those of the circuit-court are elected by the people, and their term of office is limited to four years. The revenue of the state for the two years 1851 and 1852, was $162,658, the expenditure for the same period, $135,040. The public debt in October 1852 amounted to $4,151,370.

Arkansas, though possessing many natural advantages, is far behind the neighbouring states in improvement and general prosperity, and has no direct commerce, but exports its staples through New Orleans. No railways have yet been constructed in this state, though one or two lines have lately been proposed. Education is in a very backward state; the means of instruction being utterly inadequate to the requirements of the population.

Arkansas, a vast affluent of the Mississippi. It rises in the Rocky Mountains near Lat. 42. N. Long. 109. W., and after a winding course of 2170 miles, joins that river in Lat. 33. 56. N. Long. 91. 20. W., flowing generally in an eastward direction from its source as far as Long. 99., when it inclines to the south-east during the rest of its course. It flows through a well-wooded country for 100 miles from the Rocky Mountains; but in its farther progress it traverses a long tract devoid of wood, in which it expands into a wide stream, sometimes a mile in breadth, and interspersed with islands. It passes through the Ozark Mountains, and entering the state to which it gives its name, continues its course through a rich alluvial soil. It receives several considerable tributary rivers, the principal of which are the White River and the Great Canadian. Its annual inundations commence in March, and are at their height in June. It is navigable for steamboats as far as Fort Gibson, and, when in full flood, even so far as 2000 miles from its mouth.

ARKLOW, a seaport and market-town near the southern border of the county of Wicklow, 50 miles from Dublin, containing, in 1851, 3306 inhabitants. It is situated at the extremity of the beautiful Vale of Ovoca, on the acclivity of a hill extending along the right bank of the river. The town is of mean appearance, and mainly supported by the herring fishery and the export of copper pyrites from the Ovoca mines. There are oyster-beds on the coast, but the oysters are so strongly impregnated with a peculiar flavour, supposed to be derived from the mining districts, through the Ovoca River, as to be unsaleable when first taken; but after being thoroughly purged in the purer waters of the Welsh and English coast, are remarkably delicate. The coast is much exposed, and the harbour only accessible to small vessels. Arklow formerly contained a monastery and a castle, which latter was demolished by Cromwell. During the disturbances of 1798, the insurgents were defeated by the king's troops under General Needham, in a battle fought near Arklow Bridge.

ARKWRIGHT, Sir Richard, famous for his inventions in cotton spinning, was born at Preston in Lancashire, in 1732, of parents in humble circumstances. He was the youngest of thirteen children, received but a very indifferent education, and was bred to the trade of a barber. But the *res angusta domi* could not repress the native vigour of his mind, or extinguish the desire he felt to emerge from his low situation. In the year 1760 he had established himself in Bolton-le-Moor, where he exchanged the trade of a barber for that of an itinerant hair-merchant; and having discovered a valuable chemical process for dying hair, he was in consequence enabled to amass a little property. It is unfortunate that very little is known of the steps by which he was led to those inventions that raised him to distinction, and have immortalized his name. His residence in a district where a considerable manufacture of linen goods, and of linen and cotton mixed, was carried on, must have given him ample opportunities of becoming acquainted with the various processes that were in use in the cotton manufacture, and of the attempts that had been made and were then making to improve them. His attention was thus naturally drawn to this peculiar department; and, while he saw reason to conclude that it was likely to prove the most advantageous in which he could engage, he had sagacity and good fortune to invent and improve those extraordinary machines by which, unlike most inventors, he amassed vast wealth, at the same time that he added prodigiously to the demand for labour, and to the riches and comfort of the civilized world.

The *spinning-jenny*, invented in 1767 by Hargraves, a carpenter at Blackburn in Lancashire, gave the means of spinning twenty or thirty threads at once with no more labour than had previously been required to spin a single thread. The thread spun by the jenny could not, however, be used, except as weft, being destitute of the firmness or hardness required in the longitudinal threads or warp. But Mr Arkwright supplied this deficiency by the invention of the *spinning-frame*—that wonderful piece of machinery, which spins a vast number of threads of any degree of fineness and hardness, leaving to man merely to feed the machine with cotton, and to join the threads when they happen to break. It is not difficult to understand the principle on which this machine is constructed, and the mode of its operation. It consists of two pairs of rollers, turned by means of machinery. The lower roller of each pair is furrowed or fluted longitudinally, and the upper one is covered with leather, to make them take a hold of the cotton. If there were only one pair of rollers, it is clear that a carding of cotton, passed between them, would be drawn forward by the revolution of the rollers; but it would merely undergo a certain degree of compression from their action. No sooner, however, has the carding, or *roving* as it is technically termed, begun to pass through the first pair of rollers, than it is received by the second pair, which are made to revolve with (as the case may be) three, four, or five times the velocity of the first pair. By this admirable contrivance, the roving is drawn out into a thread of the desired degree of tenuity, a twist being given to it by the adaptation of the spindle and fly of the common flax wheel to the machinery.

Such is the principle on which Mr Arkwright constructed his famous spinning-frame. It is obvious that it is radically different from the previous methods of spinning either by the common hand-wheel or distaff, or by the jenny, which is only a modification of the common wheel. Spinning by rollers was an entirely original idea; and it is difficult to determine which is most worthy of admiration—the genius which led to so great a discovery, or the consummate skill and address by which it was so speedily perfected and reduced to practice. Mr Arkwright stated that he accidentally derived the first hint of his great invention from seeing a red-hot iron bar elongated by being made to pass between rollers;[1] and though

[1] See the account of Mr Arkwright, in the article Derbyshire, in the *Beauties of England and Wales*, vol. iii. p. 518. The statements in this account are of the highest authority, inasmuch as we have reason to believe it was furnished by Mr Strutt, the son of Mr Arkwright's first partner.

there is no mechanical analogy between that operation and his process of spinning, it is not difficult to imagine, that by reflecting upon it, and placing the subject in different points of view, it might lead him to his invention. The precise era of the discovery is not known; but it is most probable that the felicitous idea of spinning by rollers had occurred to his mind as early as the period when Hargraves was engaged in the invention of the jenny, or almost immediately after. Not being himself a practical mechanic, Arkwright employed a person of the name of John Kay, a watchmaker at Warrington, to whom we shall afterwards have to refer, to assist him in the preparation of the parts of his machine. Having made some progress towards the completion of his inventions, he applied in 1767 to Mr Atherton of Liverpool for pecuniary assistance to enable him to carry them into effect; but this gentleman declined embarking his property in what appeared so hazardous a speculation, though he is said to have sent him some workmen to assist in the construction of his machine; the first model of which was set up in the parlour of the house belonging to the free grammar school at Preston.

His inventions being at length brought into a pretty advanced state, Arkwright, accompanied by Kay, and a Mr Smalley of Preston, removed to Nottingham in 1768, in order to avoid the attacks of the same lawless rabble that had driven Hargraves out of Lancashire. Here his operations were at first greatly fettered by a want of capital. But Mr Strutt[1] of Derby, a gentleman of great mechanical skill, and largely engaged in the stocking manufacture, having seen Arkwright's inventions, and satisfied himself of their extraordinary value, immediately entered, conjointly with his partner Mr Need, into partnership with him. The command of the necessary funds being thus obtained, Mr Arkwright erected his first mill, which was driven by horses, at Nottingham, and took out a patent for spinning by rollers, in 1769. But as the mode of working the machinery by horse-power was found too expensive, he built a second factory, on a much larger scale, at Cromford in Derbyshire, in 1771, the machinery of which was turned by a water-wheel, after the manner of the famous silk-mill erected by Sir Thomas Lombe. Having made several additional discoveries and improvements in the processes of carding, roving, and spinning, he took out a fresh patent for the whole in 1775; and thus completed a series of machinery so various and complicated, yet so admirably combined, and well adapted to produce the intended effect, in its most perfect form, as to excite the astonishment and admiration of every one capable of appreciating the ingenuity displayed and the difficulties overcome.[2]

When the vast importance of these discoveries became known, it is not surprising that every effort should have been made to have the patents set aside, and Mr Arkwright deprived of the profit and honour to be derived from them. But after a pretty attentive consideration of the various proceedings relative to this subject, we have no hesitation in saying, that we see no good grounds for crediting the statement made in the court of king's bench in 1785, and again repeated by Mr Guest in his work on the cotton manufacture, which ascribes the invention of spinning by rollers to Highs or Hayes, from whom Arkwright is said to have learned it; and we shall now briefly state our reasons for holding this opinion.

Mr Arkwright's *first* patent for spinning by rollers, which is by far the most important, or rather, indeed, the essential part of his inventions, was obtained, as we have previously stated, in 1769; and its value and importance were no longer doubtful after the establishment of the factory at Cromford in 1771. The success which attended this novel method of spinning naturally excited the strongest desire on the part of the Lancashire manufacturers to participate in the advantages to be derived from it; and the fair presumption is, that instead of attempting clandestinely to pirate the invention, they would, had they conceived there were any good grounds to go upon, have at once contested the validity of the patent. But no such attempt was made till 1781, *twelve* years after the date of the first patent, and *six* years after the date of the second. And, even at that late period, Mr Arkwright's opponents came forward only in consequence of his having resolved to vindicate his rights, which had begun to be invaded on all sides, by raising an action against Colonel Mordaunt for an infringement of his patent. Mordaunt was supported by a combination of manufacturers; and, as they felt the question to be of the greatest importance, it is all but impossible to suppose that any thing would be omitted on their part which was conceived likely to contribute to their success. The case having been tried in the court of king's bench, after Trinity term, July 1781, the decision was unfavourable to Mr Arkwright. But it is of importance to observe, that no attempt was made at the trial to charge him with having purloined the inventions of others, and that the verdict was given on the sole ground of the *description of the machinery in the specification being obscure and indistinct.* Mr Arkwright admitted that such was partly the case; adding, however, that the obscurity charged against the specification had been intended only to prevent foreigners from pirating his inventions. On any other principle, indeed, his conduct would be inexplicable; for, as his inventions were fully known to hundreds of workmen in his own employment, and as he had sold the privilege of using them to great numbers of individuals in different parts of the country, it is impossible to suppose that he could either have expected or intended to conceal his inventions after the expiration of his patent.[3] In consequence of the result of this trial, Mr Arkwright and his partners prepared a *Case*, setting forth the value of the inventions, and the circumstances which had led to the indistinctness complained of in the specification, which they at one time intended to lay before parliament, as the foundation of an application for an act for their relief. But this intention was subsequently abandoned; and in a new trial (Arkwright *v.* Nightingale), which took place in the court of common pleas on the 17th of February 1785, Lord Loughborough, the presiding judge, having expressed himself favourably with respect to the sufficiency

[1] This was the justly celebrated Mr Jedediah Strutt. He was the son of a farmer, and was born in 1726. His father paid little attention to his education; but, under every disadvantage, he acquired an extensive knowledge of science and literature. He was the first individual who succeeded in adapting the stocking-frame to the manufacture of *ribbed* stockings. The manufacture of these stockings, which he established at Derby, was conducted on a very large scale, first by himself and his partner Mr Need, and subsequently by his sons, until about 1805, when they withdrew from this branch of business.

[2] See the *Case* of Richard Arkwright & Co. in 1782; the account of Sir Richard Arkwright in Aikin's *Biographical Dictionary*: the *History, Gazetteer, &c. of Lancashire*, by Edward Baines, vol. ii. p. 484, &c.

[3] It was erroneously stated, in an article in the *Edinburgh Review* (No. 91), from which this sketch is principally abstracted, on the authority of the article "Cotton Manufacture," in the Supplement to this work (vol. iii. p. 394), that a trial had been instituted in 1772, in which Mr Arkwright proved successful, to have the original patent set aside. But the first trial did not really take place, as above stated, till 1781.

of the specification, a verdict was given for Mr Arkwright. On this, as on the former trial, nothing was stated against the originality of the invention.

In consequence of these conflicting verdicts, the whole matter was brought, by a writ of *scire facias*, before the court of king's bench, to have the validity of the patent finally settled. And it was not till this third trial, which took place before Mr Justice Buller and a special jury, on the 25th of June 1785, that Mr Arkwright's claim to the inventions which formed the subject of the patent was disputed. To support this new allegation, Mr Arkwright's opponents brought forward, for the first time, Highs or Hayes, a reed-maker at Bolton. He stated that he had invented a machine for spinning by rollers previously to 1768; that he had employed the watchmaker Kay, to whom we have already referred, to make a model of that machine; and Kay was produced to prove that he had communicated that model to Mr Arkwright, and that that was the real source of all his pretended inventions. Having no idea that any attempt was to be made at so late a period to overturn the patent on this new ground, Mr Arkwright's counsel were not prepared with evidence to repel this statement; but it was stated by Mr Sergeant Adair, on a motion for a new trial on the 10th of November of the same year, that he was furnished with affidavits contradicting, in the most pointed manner, the evidence that had been given by Kay and others with respect to the originality of the invention. The court, however, refused to grant a new trial, on the ground, that whatever might be the fact as to the question of originality, the deficiency in the specification was enough to sustain the verdict.

But, independently altogether of the statements made on the motion for a new trial, the improbability of the story told by Highs and Kay seems glaring and obvious. Highs states in his evidence that he had accused Arkwright of getting possession of his invention by means of Kay so early as 1769, or about that period. Where, then, it may be asked, was this Mr Highs ever since that period, and particularly during the first trial in July 1781, and the second in February 1785? Living in Lancashire, associating with manufacturers, and in the habit, as he declares in his evidence, of making machines for them, he could not fail to be speedily informed with respect to the vast importance and value of the invention Mr Arkwright had purloined from him. It is impossible but he must have been acquainted with the efforts that were making by the Lancashire manufacturers to set aside the patents; and is it to be supposed, had he really been the inventor, that he would have remained for *sixteen* years a passive spectator of what was going forward? that he would have allowed Mr Arkwright to accumulate a princely fortune by means of *his* inventions, while he remained in a state of poverty? or that he would have withheld his evidence when the manufacturers attempted to wrest from Mr Arkwright what he had so unjustly appropriated? A single hint from Highs or Kay would, had their story been well founded, have sufficed to force Mr Arkwright to give them a share of his profits, or would have furnished the manufacturers with the means they were so anxious to obtain, of procuring the immediate dissolution of the patents. But it has never been alleged that Mr Arkwright took any pains to conciliate these persons: on the contrary, he treated Highs with the most perfect indifference, and not only dismissed Kay from his service, but even threatened to prosecute him on a charge of felony. And can any one imagine for a moment, that persons with so many and such overpowering temptations to speak out, and with no inducement of any sort to be silent, should have gone about for more than twice the period of a Pythagorean noviciate, with so important a secret closely pent up in their bosoms? We confess that such a supposition seems to us altogether absurd and incredible; and we believe our readers will agree with us in thinking, that it is infinitely more consistent with probability to suppose that the story of Highs and Kay had been manufactured for the occasion, than that it was really true.

The improbability of the statements made on this subject by Guest, in his *History of the Cotton Manufacture*, appear still more obvious, from his attributing to Highs the invention, not only of the spinning frame, but also of the jenny, which had been universally ascribed to Hargraves. But no weight can be attached to such rash and ill-considered statements. It would be next to a miracle, had two methods of spinning, both very ingenious, but radically different in their first principles, been invented nearly at the same time by the same individual.

It appears, from a communication from Mr Charles Wyatt to his brother, in the *Repertory of Arts* for 1817, and which has been reprinted by Mr Kennedy, in an interesting article on the Rise and Progress of the Cotton Trade, in the *Manchester Memoirs* (2d series, vol. iii. p. 135), as well as from the distinct reference to them in the *Case* printed by Mr Arkwright in 1782, that attempts had been made in the early part of last century to spin cotton by means of machinery. But these attempts proved ruinous to the parties by whom they were made; and all knowledge of the machinery by which they attempted to effect their purpose has been long since lost. Mr Kennedy says he had seen a specimen of yarn spun about 1741, by the late Mr Wyatt of Birmingham; but he expresses his opinion that no competent judge would say that it was spun by a similar machine to that of Mr Arkwright. It was not indeed alleged at any of the trials that took place with respect to the validity of his patent, nor has it ever been alleged since, that he had borrowed anything whatever from these remote attempts. If he was really indebted to them, it must have been merely for the knowledge of the fact that such attempts had been made; and this might have stimulated him to turn his attention to the subject.

We have access to know that none of Mr Arkwright's most intimate friends, and who were best acquainted with his character, ever had the slightest doubt with respect to the originality of his invention. Some of them, indeed, could speak to the circumstances from their own personal knowledge; and their testimony was uniform and consistent. Such also seems to be the opinion now generally entertained among the principal manufacturers of Manchester. In proof of this, we may again refer to Mr Kennedy's valuable paper in the *Manchester Memoirs*. Mr Kennedy is one of the most eminent and intelligent cotton manufacturers in the empire, and it is of importance to remark, that, although he was resident in Manchester in 1785, when the last trial for setting aside Mr Arkwright's patent took place, and must, therefore, have been well acquainted with all the circumstances connected with it, he does not insinuate the smallest doubt as to his being the real inventor of the spinning frame, nor even so much as once alludes to Highs.

On their first introduction, Mr Arkwright's machines were reckoned by the lower classes as even more adverse to their interests than those of Hargraves; and reiterated attacks were made on the factories built for them.[1] But

[1] Dorning Rasbotham, Esq. a magistrate near Bolton, printed, some time about the period referred to, a sensible address to the weavers and spinners, in which he endeavoured to convince them that it was for their interest to encourage inventions for abridging

how extraordinary soever it may appear, it was amongst the manufacturers that the greatest animosity existed against Mr Arkwright, and it required all the prudence for which he was so remarkable to enable him to triumph over the powerful combination that was formed against him. At the outset of the business, they unanimously refused to purchase his yarn; and when his partners, Messrs Strutt and Need, had commenced a manufacture of calicoes, the manufacturers strenuously opposed a bill to exempt calicoes from a discriminating duty of 3d a yard laid on them, over and above the ordinary duty of 3d by an old act of parliament. Luckily, however, the manufacturers failed of their object; and, in 1774, an act of parliament was obtained (14th Geo. III. cap. 72), for the encouragement of the cotton manufacture, in which fabrics made of cotton are declared to have been *lately* introduced, and are allowed to be used as "a lawful and laudable manufacture;" the duty of 6d the square yard on such cottons as are printed or stained being at the same time reduced to 3d. But this disgraceful spirit of animosity, which must, had it been successful, have proved as injurious to the interests of the manufacturers as to those of Mr Arkwright, did not content itself with actions in the courts of law, or a factious opposition to useful measures in parliament, but displayed itself in a still more striking and unjustifiable manner; for it is a fact, that a large factory, erected by Mr Arkwright at Birkacre, near Chorley, in Lancashire, was destroyed by a mob collected from the adjacent country, in the presence of a powerful body of police and military, without any one of the civil authorities requiring them to interfere to prevent so scandalous an outrage.

Fortunately, however, not for himself only, but for his country and the world, every corner of which has been benefited by his inventions, Mr Arkwright triumphed over every opposition. The same ingenuity, skill, and good sense, which had originally enabled him to invent his machine and get it introduced, enabled him to overcome the various combinations and difficulties with which he had subsequently to contend.

Though a man of great personal strength, which he is said to have displayed when young, in election riots at Preston, Mr Arkwright never enjoyed good health. During the whole of his splendid and ever memorable career of invention and discovery, he was labouring under a very severe asthmatic affection. A complication of disorders at length terminated his truly useful life in 1792, at his works at Cromford, in the sixtieth year of his age. He was high sheriff of Derbyshire in 1786; and, having presented a congratulatory address from the wapentake of Wirksworth to his majesty George III., on his escape from the attempt on his life by Margaret Nicholson, received the honour of knighthood. No man ever better deserved his good fortune, or has a stronger claim on the respect and gratitude of posterity. His inventions have opened a new and boundless field of employment; and while they have conferred infinitely more real benefit on his native country than she could have derived from the absolute dominion of Mexico and Peru, they have been *universally* productive of wealth and enjoyments.

"The originality and comprehensiveness of Sir Richard Arkwright's mind," says Mr Bannatyne, "was perhaps marked by nothing more strongly than the judgment with which, although new to business, he conducted the great concerns his discovery gave rise to, and the systematic order and arrangement which he introduced into every department of his extensive works. His plans of management, which must have been entirely his own, as no establishment of a similar nature then existed, were universally adopted by others; and, after long experience, they have not yet, in any material point been altered or improved." (J. R. M.)

ARLAND, Jacques Antoine, a celebrated miniature painter, born at Geneva in 1668. He came to England in 1721, where he made a considerable fortune, and had a great reputation. He returned to his native country, and died there in 1743.

ARLES, an arrondissement in the department of the Mouths of the Rhone, in France, extending over 900 square miles, or 576,124 acres. It is divided into eight cantons, and subdivided into thirty-one communes, which in 1851 contained 87,749 inhabitants.

Arles (the ancient *Arelas*, or *Arelate*), a city of France, in the department of Bouches du Rhone, and capital of an arrondissement of its own name, 46 miles north-west of Marseilles, with which, and with Avignon, it is connected by railway. Lat. 43. 40. 18. N. Long. 4. 37. 46. E. It stands on the left bank of the Rhone, where that river divides to form its Delta; and to obviate the inconvenience of the difficult navigation, the *Canal d'Arles* has been constructed, extending to the harbour of Bouc on the Mediterranean, a distance of 25 miles. It is also connected with the canal of Beaucaire, and by that of Craponne with the Durance. The town is inclosed with old walls; the streets are narrow, dirty, and intricate; and the houses generally are old and mean. The marshes in the vicinity render it somewhat unhealthy. It has a handsome town-hall, an ancient cathedral, a college, school of navigation, museum, public library, docks for ship-building, &c. The principal manufactures are silk, soap, glass bottles; and its sausages are famous. The trade also in agricultural produce, cattle, wool, and salt, is considerable. Pop. in 1846, 14,239.

Arles possesses many magnificent and interesting monuments of its ancient grandeur. The remains of its amphitheatre, which was capable of containing from 25,000 to 30,000 spectators, measure 459 feet in length by 338 feet in width. It has also remains of a Roman theatre, in which the celebrated statue known as the "Venus of Arles" was discovered in 1651; the ruins of two temples, an aqueduct, a triumphal arch, and an extensive cemetery containing many sarcophagi, the *Elysii campi* of the Romans, whence its modern appellation of *Aliscamps*. In front of the town-hall, and in the centre of the *Place Royale*, is a plain granite obelisk of a single block 47 feet long, erected on a pedestal 20 feet in height. This obelisk, which had long lain buried in the earth, was elevated to its present position in 1676. It was once supposed to be Egyptian, but it is now ascertained to have been brought from a quarry in the Estrelle Mountains near Frejus; besides, it tapers more rapidly than those of Egypt, and has no hieroglyphics. Arelate was an important town when Cæsar invaded Gaul. Subsequently, a Roman colony was established there; and in the time of the Emperors it became one of the most flourishing towns on this side of the Alps. After being pillaged A.D. 270, it was repaired, embellished, and greatly enlarged by Constantine; and here his son Constantine II. was born. On

labour. The result has shown the soundness of Mr Rasbotham's opinion. It is doubtful whether 30,000 persons were employed in all the branches of the cotton manufacture in 1767; whereas, in consequence of those very inventions which the workmen endeavoured to destroy, there are now upwards of 1,000,000 directly engaged in its different departments! There is, in fact, no idea so groundless and absurd as that which supposes that an increased facility of production can, under any circumstances, be injurious to the labourers.

the fall of the Roman empire, Arelate came into the power of the Visigoths, and rapidly declined; and in 730 it was plundered by the Saracens. In 933 it became the capital of a kingdom of the same name, formed by the union of the two kingdoms of Burgundy (Cisjurian and Transjurian). In the twelfth century it formed a republic; and in 1251 it submitted to Charles of Anjou, Count of Provence, and was united to the crown with that province in the reign of Louis XI. Many ecclesiastical councils have been held here; the most important of which was that against the Donatists in 314.

ARMADA, a Spanish term, signifying a fleet of men of war. The armada which attempted to invade England in the time of Queen Elizabeth is famous in history. See England

ARMADILLO, in *Zoology*. See Mammalia, *Index*.

ARMAGEDDON, properly "the Mountain of Megiddo," a city on the west of the river Jordan, rebuilt by Solomon (1 Kings ix. 15). Both Ahaziah and Josias died there. The same spot witnessed, at an earlier period, the greatest triumph of Israel, when "fought the kings of Canaan in Taanach by the waters of Megiddo" (Judg. v. 19). "He gathered them together into a place called in the Hebrew tongue Armageddon," is the language of the Apocalypse; a passage which has given rise to much ingenious speculation.

ARMAGH, an inland county, in the province of Ulster, in Ireland, situate between Lat. 54. 3. and 54. 31. N., and Long. 6. 14. and 6. 45. W.; comprising, according to the ordnance survey, an area of 512½ square miles, or 328,076 acres, of which 265,243 are arable, 35,117 uncultivated, 8996 in plantations, 778 in towns, and 17,942, including a portion of Lough Neagh, under water. It is bounded on the north by Lough Neagh, on the east by the county of Down, on the the south by Louth, and on the west by Monaghan and Tyrone.

The county was made shire ground in 1586, and called Armagh after the city of the same name, by the Lord Deputy, Sir John Perrott, who projected the division of the greater part of the province of Ulster into seven counties. When James I. proceeded to plant with English and Scotch colonists, the vast tracts of land escheated to the crown in Ulster, the whole of the arable and pasture land in Armagh, estimated at 77,800 acres, was to have been allotted in 61 portions, 19 of which, comprising 22,180 acres were to have been allotted to the church, and 42, amounting to 55,620 acres, to English and Scotch colonists, servitors, native Irish, and four corporate towns,—the swordsmen to be dispersed throughout Connaught and Munster. This project was not strictly adhered to in the county of Armagh, neither were the Irish swordsmen or soldiers transplanted into Connaught and Munster from this or some other counties.

Armagh is now divided into eight baronies, viz., Armagh, Fews Lower and Upper, Oneiland East and West, Orior Lower and Upper, and Turenny. It contains 28 parishes and parts of parishes, the greater number of which are in the archdiocese of Armagh, and a few in the diocese of Dromore. The county is in the Belfast military district, having barracks at Armagh, Charlemont, and Newry, and the headquarters of the county militia are at Markethill. The constabulary force consists of 278 men and officers, with headquarters at Armagh, and five districts, comprising 36 stations, at Armagh, Ballybot, Crossmaglen, Newtown-Hamilton, and Portadown. Assizes are held at Armagh, where the county prison, the county infirmary, and the district lunatic asylum are situated. The only savings bank in the county is at Armagh. There are two poor-law unions, Armagh (partly in Tyrone) and Lurgan (partly in Antrim and Down). The amount of property in the county, valued under the act 6th and 7th Will. IV., cap. 84 (Griffith's Valuation), is L.236,860, and the net annual value of property rated to the poor is L.310,061. The chief towns are the city and borough of Armagh, population in 1851, 9306; Lurgan, 4211; Portadown, 3091; the smaller market-towns of Tanderagee, Markethill, and Newtown-Hamilton, part of Newry also, with 3875 inhabitants, is in this county, the remainder, with 9616 inhabitants, being in the county of Down. The county returns three members to the Imperial Parliament, two for the county at large,—constituency in 1851, under 13th and 14th Vict., cap. 69, 4321; and one for Armagh city,—constituency 318.

Armagh is supposed to have formed part of the district described by Ptolemy as the possessions of the Vinderii and Voluntii; and afterwards, together with Louth, Monaghan, and some smaller districts, formed part of a territory called Orgial or Urial. For about two centuries it was subject to the occasional incursions of the Danes. The antiquities of the county consist of cairns and tumuli, the remains of the fortress of Eamania near Armagh, once the residence of the kings of Ulster; the Dane's Cast, an extensive fortification in the south-eastern portion of the county, extending into the county of Down; spears, battle-axes, collars, rings, amulets, medals of gold, ornaments of silver, jet, and amber, &c., have also been found in various places. The religious houses were at Armagh, Clonfeacle, Killevy, Kilmore, Stradhailloyse, and Tahenny. Of military antiquities the most remarkable are Tyrone's ditches, near Poyntz-Pass, Castle Roe, the fort of Navan, the castles of Criff-Keirn and Argonell, and that in the pass of Moyrath.

The general surface of the county is gently undulating and pleasingly diversified; but in the northern extremity, on the borders of Lough Neagh, is a considerable tract of low marshy land, and the southern border of the county is occupied by a barren range of hills, the highest of which, named Slieve Gullion, attains an elevation of 1893 feet, being the highest mountain in Ulster excepting Slieve Donard in the county of Down. The summit of Slieve Gullion, commanding one of the finest prospects in the province, is crowned by a large cairn or pile of stones which forms the roof of a singular cavern of artificial construction. In the western portion of the county are the Few Mountains, a chain of abrupt hills mostly incapable of cultivation.

The soil of the northern portion of the county is a rich brown loam, on a substratum of clay or gravel, with an abundance of limestone near Armagh and other places. Towards Charlemont there is much reclaimable bog resting on a limestone substratum. The eastern portion of the county is generally of a light friable soil; the southern portion rocky and barren, with but little bog except in the neighbourhood of Newtown-Hamilton. The climate of Armagh is considered to be one of the most genial in Ireland, and less rain is supposed to fall in this than in any other county.

The county is well watered by numerous streams; the principal are the Callen, the Tynan, and the Tallwater, flowing into the Blackwater, which after forming part of the boundary between this county and Tyrone, empties itself into the south-western angle of Lough Neagh. The Tara, the Newtown-Hamilton, the Creggan, and the Fleury, flow into the Bay of Dundalk. The Cam or Camlin joins the Bann, which, rising in the Mourne Mountains, in the southern extremity of the county of Down, forms part of the western boundary of Armagh county, and falls into Loch Neagh to the east of the Blackwater. The Newry canal, communicating with Carlingford Lough at Warrenspoint, six miles below Newry, proceeds northwards through the county of Armagh for about 21 miles, joining the Bann at Whitecoat, in the bed of which river it is continued to Lough Neagh. The tolls, arising from tonnage dues of one shilling per ton inwards and one penny per ton outwards, amount to about L.5000 per annum. The Ulster Canal commences at Charlemont on the River Blackwater, near its junction with Lough Neagh, proceeding through the western border of the county and passing thence to the south-west by Monaghan and Clones into Upper Lough Erne, after a course of 48 miles.

The geological features of the county are various and interesting. The granite of Slieve Gullion, an offset of the granite district of Down, is often used for millstones, being very hard and fine grained. The Newry Mountains and the Fathom Hills are also composed of granite. Around Camlough large beds of mica-slate exist. Slate quarries have been worked partially at Dorcy, Newtown-Hamilton, Creggan Duff, and in the neighbourhood of Crossmaglen. Lead mines have been worked, but

hitherto without much success, near Keady and at Derrynoose near Middleton; there are also indications of lead at Drumnahoney near Markethill, and at Ballymore near Poyntz-Pass; of copper at Killevy near Newry, and of manganese and antimony in the neighbourhood of Keady. The other mineral substances found are potters' clay and a variety of ochres. A very peculiar deposit of fuel more recent than coal, viz., the lignite or wood-coal of Lough Neagh is found in the district included between Washing Bay in Tyrone and Sandy Bay in Antrim; it is so abundant in some places that pits have been sunk to raise it when other fuel was scarce. Sir Robert Kane states in his work on the *Industrial Resources of Ireland*, that the economic value of the lignite appears by analysis to be about two-thirds that of average coal, and in all respects as to application to industrial uses the position of lignite is between that of coal and wood. The heat produced from it is more diffused but less intense than that from coal. There are many mineral springs scattered throughout the county, generally deriving their virtues from carbonate of iron, but none have hitherto been employed medicinally.

The total population in 1821 amounted to 197,427 souls, being at the rate of one individual to every acre and a-half, or one family to every eight acres. Of this population, 28,905 were described as being employed in agriculture, 67,182 in trade, manufactures, and commerce, and 14,521 in other occupations, leaving 86,819 of both sexes and of every age unoccupied. In 1831 and 1841 the population was 220,134 and 232,393 respectively, but in 1851 the numbers had declined to 196,085, inhabiting 35,073 houses. Armagh, however, still remains, in proportion to its area, the most densely peopled county in Ireland, excepting that of Dublin, which includes the metropolis.

The land is in general but indifferently cultivated, yet owing to the occupation of the peasantry in various branches of the linen manufacture they are better lodged, clothed, and fed than in most other parts of Ireland. The cultivation of grain is somewhat on the decrease; that of green crops, on the contrary, increases, and the number of acres under flax had increased from 5181 in 1849 to 13,052 in 1851. The total amount of land under crops amounted in 1851 to 175,662, viz., wheat, 16,320; oats, 77,347; barley, bere, and rye, 3314; beans and pease, 1168; potatoes, 31,887; turnips 7870; other green crops, 3071; flax, 13,032; meadow and clover, 21,632.

In consequence of the dense population the farms are in general very small, and show less tendency to decrease in number than those of most other parts of Ireland. Notwithstanding the very diminutive size of the farms, their owners are generally in circumstances of comparative comfort, owing to their employment in the linen manufacture. There are few who do not keep at least one cow, or a few sheep; none but the poorest cottar is without a pig. Their usual diet is oatmeal, potatoes, and milk porridge, varied sometimes by salt herrings. The better description of farmers use animal food, chiefly bacon and poultry.

The principal manufacture, and that which has given a peculiar tone to the character of the population is the linen. It is noways necessary to the promotion of this manufacture that the spinners and weavers should be congregated in large towns, or united in crowded and unwholesome factories. On the contrary, most of its branches can be carried on in the cottages of the peasantry. The men devote to the loom those hours which are not required for the cultivation of their little farms; the women spin and reel the yarn during the intervals of their other domestic occupations. Smooth lawns, perennial streams, pure springs, and the open face of heaven, are necessary for perfecting the bleaching process. Hence the extensive bleachers, with all their assistants and machinery, dwell in the country. Such is the effect of this combination of agricultural occupations with domestic manufactures, that the farmers are more than competent to supply the resident population of the county with vegetable, though not with animal, food; and some of the less crowded and less productive parts of Ulster receive from it a considerable supply of oats, barley, and flour. Apples are grown in such quantities as to entitle the county to the epithet bestowed on it, of the orchard of Ireland.

Armagh.

In the towns and level parts of the county the Protestant religion, in its two principal forms of the Established Episcopal and Presbyterian church, predominates; but the Roman Catholic is prevalent in the mountainous and less cultivated parts. As far as may be conjectured from the returns of the commissioners of education, the Roman Catholics constitute nearly one half of the gross population.

According to those returns, the number of children at school in 1824 amounted to 13,800. If the total number of children between five and fifteen years of age, which may be called the period of education, were 49,000, as stated in the population returns of 1821, upwards of two-thirds of the whole remained uninstructed. In 1851, there were 111 national schools in operation, attended by 9458 children; 5500 males and 3958 females.

The union of manufacturing and agricultural industry in contributing to their prosperity, has also had a strikingly favourable effect on the manners and appearance of the people. (H. S—R.)

Armagh, a city and parliamentary borough, in the county of the same name, 82 miles north of Dublin, in Lat. 54. 20. 55. N. and in Long. 6. 37. 57. W. It is delightfully situated on the side of a steep hill, almost in the centre of a fertile valley. With the exception of Kilkenny and Clonmel, Armagh is the most populous inland town in Ireland. It is the seat of the archiepiscopal see of the primate of all Ireland, whose ecclesiastical province comprises six consolidated dioceses. 1. Armagh and Clogher; 2. Tuam, Ardagh, Killala, and Achonry; 3. Derry and Raphoe; 4. Down, Connor, and Dromore; 5. Kilmore and Elphin; 6. Meath. The corporation which was styled "the Sovereign, Free Burgesses, and Commonalty of the Borough of Armagh," was abolished by the provisions of the Municipal Reform Bill. Markets are held on Tuesdays for general purposes, and on Wednesdays and Saturdays for grain. The city is connected with Belfast by the Ulster Railway, and will on the completion of the Newry and Enniskillen railway, possess direct communication with those towns. The borough of Armagh (constituency in 1851, 318) returns one member to the Imperial parliament. Pop. in 1851, 9306.

Armagh, though now much reduced in population, was once considered as the metropolis of the island, and second only to Dublin in the number of its inhabitants. The honour of being its founder is attributed to St Patrick. It was built on an eminence named Druimsailech, or the Hill of Willows; its present name is supposed to be a slight corruption of Ardmacha, the High Place or Field. In 448 a synod was held here, the canons of which are still in existence. During the period anterior to the arrival of the English in Ireland, it suffered extremely from the assaults of the Danes, by whom it was repeatedly plundered and burnt. Nor was its condition much bettered by the change of masters. De Courcy, FitzAdelm, and De Lacy, pillaged it in turn in their attempts to subdue Ulster; and it was exposed to similar calamities during the wars by which the north of Ireland was desolated in the reign of Elizabeth. Her successor, James I., granted it a charter, according to which it has since been governed. Its decline was accelerated by the non-residence of the archbishops, who, in consequence of the unsettled state of the northern province, fixed their residence for many years at Drogheda. From this deplorable state it was raised by Lord Rokeby, better known by the name of Primate Robinson. When he determined to make it the seat of his permanent residence, this venerable city was little more than a collection of cabins. He erected in it an archiepiscopal palace, a college or grammar school for classical education, a public library, now containing about 14,000 volumes, and an observatory well furnished with astronomical instruments. Besides these, the city now contains a Roman Catholic

chapel, a Roman Catholic cathedral in course of erection, three Presbyterian churches, and several places of worship for other religious denominations. Its other public buildings are, the cathedral, a cruciform building, repaired and beautified chiefly at the expense of the present primate, more remarkable for its antiquity than its architectural beauty, the court-house, the prison, the charter-school, the barrack, the county infirmary, the lunatic asylum, and the fever hospital, which last was erected and is maintained at the expense of Lord John George Beresford, the present primate. (H. S—R.)

ARMAGNAC, a small territory of France, in the old province of Gascony, now forming a part of the departments of Gers, Haut Pyrenees, and Tarn and Garonne. It gave a title to the descendants of the ancient dukes of Gascony and Aquitaine. The counts of Armagnac bore a conspicuous part in the wars of France and England in the fifteenth century. See FRANCE.

ARMATURA, in a general sense, is synonymous with *armour*. It is more particularly used in the Roman military art to denote a kind of exercise performed with missile weapons. In this sense armatura stands contradistinguished from palaria; the latter being the exercise of the heavy-armed, the former of the light-armed.

ARMENIA, an extensive country of Western Asia, divided at present between Turkey, Russia, and Persia. It extends from the Caucasus on the north, to the mountains of Kurdistan on the south; and from the Euphrates on the west, nearly to the Caspian Sea on the east; being thus between Lat. 37. and 42. N. and Long. 39. and 50. E. The boundaries of this country, however, have been very fluctuating, and at no time exactly defined. Its area is estimated at about 90,000 square miles, and the population at 2,000,000. It forms an elevated table-land, sinking towards the plains of Iran on the east, and those of Asia Minor on the west. Its plains are elevated 7000 feet above the level of the sea, while the gigantic Ararat rises to the height of 17,260 feet. From Ararat lofty ridges, intersected by deep valleys, diverge in various directions. Armenia is well watered and fertile, producing grain, cotton, tobacco, grapes, and other fruits; and abounds in romantic mountain and forest scenery, and rich pasture land. Its principal rivers are the Euphrates, the Tigris, the Aras, and the Kur, all of which have their sources in Armenia. The climate, from the elevation of the country, is generally cold, but not unhealthy. The largest of its lakes is the Van, whose circumference is estimated at 240 miles. The Sevan and Urmia Lakes are also of considerable extent, and the waters of the latter are remarkable for their saltness. Armenia is mentioned by ancient authors as abounding in metals and precious stones; and its mines of iron, copper, silver, lead, and other metals, are still wrought.

Under the name of Armenia, ancient writers included a considerable part of Asia Minor, to which was afterwards given the name of Armenia Minor.

The Armenians call themselves *Haiks*, and their country *Hayotz-zor*, the valley of the Haiks, from Haik, the fifth in descent from Noah by Japhet, according to the traditionary genealogy of the country. They are active, industrious, and hospitable; and are a handsome race, the women especially being noted for the delicacy and regularity of their features. The Armenians now form only about a seventh part of the population of Armenia, the rest of its inhabitants being chiefly Turks and Kurds. From the persecutions and tyranny to which they have been exposed, most of them have left their country, and though originally a brave and warlike people, they have become distinguished for their peaceful character, and their submissiveness to the government of every country in which they live. Devoted to trade and manufactures, they have prospered wherever they have settled; and their scattered colonies now extend from Hungary and Venice to Calcutta, and even to China, and from St Petersburg and Moscow to the deserts of Africa. They generally live in large families, under the patriarchal rule of the oldest member. Their religion is a branch of the Oriental Church. They have few holidays, and condemn the worship of images. Their spiritual concerns are superintended by four patriarchs, of whom the principal, called the Catholicos, resides at the convent of Etchmiadzin, near Erivan. One resides at Sis in Caramania; another at Gand sasar, near the Lake of Erivan; and the fourth at Achtamar, an island in the Lake of Van. Some Armenians have united with the Church of Rome, and have two archbishops, one at Nachshivan on the Don, and the other at the Island of San Lazaro, in the lagunes of Venice.

The early history of Armenia, like that of most other countries, is involved in obscurity. According to the Armenian account, the first ruler of the country was Haik the son of Togarmah, mentioned in Gen. x. 3. as the grandson of Japhet. He is said to have left Babylon to escape the tyranny of Belus king of Assyria, and to have established himself and his family in Armenia. Belus pursued him thither, but was defeated and slain by Haik about twenty-one centuries before the Christian era. Four centuries later reigned Ara, the seventh in descent from Haik, who having incurred the hatred of Semiramis queen of Assyria, was slain in a battle with that nation, and his kingdom became an Assyrian province, although it still continued to be governed by its own princes. From this time Armenia remained subject to Assyria till about the middle of the eighth century B.C. Barvir, who was then ruler, joined the Medes and Babylonians in their revolt against Sardanapalus, and Armenia recovered its independence. Tigranes or Dikran, who flourished about two centuries later, was the friend and ally of Cyrus, and is said to have rendered that monarch great assistance in his contest with Astyages king of the Medes. According to the Armenians, this is the Tigranes who built the city of Tigranocerta. He was succeeded by his son Vahakin, the Hercules of the Armenians, who was celebrated in song and story for his prowess and exploits, and received deification after death. The last of the Haik dynasty was Vahi, who was king of Armenia in the time of Alexander the Great. He took part with Darius against the Macedonians, but was defeated and slain. Armenia thus fell into the hands of the conqueror; and Mithrenès, a Persian, was appointed governor of the country. Taking advantage of the dissensions which followed the death of Alexander the Great, the Armenians threw off the Macedonian yoke, about B.C. 317. Ardvates was chosen king; but on his death, about 33 years afterwards, they were obliged to submit to the Syrians. About B.C. 190, when Antiochus the Great was defeated by the Romans, Artaxias and Zariadris, two Armenian nobles, took advantage of the moment to free their country from the Syrian yoke. Artaxias obtained possession of Armenia-Major, and Zariadris of Armenia-Minor, which his descendants continued to hold till the Sophenian Artanes was conquered and deposed by Tigranes II. king of Armenia-Major, who annexed it to his dominions. The descendants of Artaxias reigned in Armenia till their expulsion by the Arsacidæ. About the middle of the second century B.C., Mithridates I., of the race of the Arsacidæ, was king of Parthia. He greatly extended the bounds of his empire, conquered Syria, and established his brother Wagharshag in Armenia, B.C. 149. With him commenced the dynasty of the Arsacidæ in that country. Wagharshag greatly promoted the prosperity of his kingdom by founding cities, establishing laws, and rewarding persons of talent. His great-grandson, Tigranes II., the most celebrated of the family, ascended the throne in the year 89 B.C. He conquered Artanes king of Sophene, besides several other petty chiefs, and annexed their dominions to his own. He wrested from the Parthians several of their provinces, and made himself master of Syria, and was so elated with successes, that he assumed to himself the title of King of kings.

Incited by his father-in-law Mithridates king of Pontus, who was anxious to engage him in a war with the Romans, he marched into Cappadocia, and returned loaded with booty, besides no fewer than 300,000 captives, whom he employed in building the city of Tigranocerta, which they afterwards peopled: the Armenian historians, however, state that it was Tigranes I. who founded his city. After the defeat of Mith-

ridates he took refuge with Tigranes, who, though he manifested no inclination to espouse his cause, was so much offended at the haughty manner of the Roman messenger sent to demand the fugitive, that he returned a peremptory refusal. Lucullus, the Roman general, immediately invaded Armenia, defeated the forces sent against him, and took Tigranocerta. In the following year (B.C. 68) the combined forces of Tigranes and Mithridates were totally routed; but the mutinous disposition of the Roman troops prevented Lucullus from following up his success, and Tigranes recovered the greater part of his lost dominions. The arrival of Pompey, however, in 66, soon changed the aspect of affairs; and Mithridates, who had succeeded in establishing himself in his former possessions, was again obliged to take refuge in Armenia. Tigranes in the meantime had another enemy to encounter in the person of his son, who being detected in a conspiracy against his father, sought the protection and assistance of the Parthian king. That monarch invaded Armenia with a considerable force, but was soon obliged to retire, and the young Tigranes applied to the Romans for assistance. It was at this time that Mithridates implored the protection of his son-in-law; but Tigranes suspecting him of having aided the designs of his son, not only refused to receive him, but set a price upon his head, and hastened to supplicate Pompey who was entering his kingdom under the guidance of the young Tigranes. He succeeded in obtaining peace, and was allowed to keep possession of Armenia, with the exception of the provinces of Sophene and Gordyene, which were erected into a separate kingdom for his son Tigranes; and from this time he remained a faithful ally of the Romans. He afterwards engaged in war with the king of Parthia, but their differences were settled by the mediation of Pompey. He is supposed to have died about B.C. 55, and was succeeded by his son Artavasdes. This monarch, having deserted the cause of the Romans, was taken prisoner by Antony and carried to Alexandria, where he was afterwards beheaded by Cleopatra in B.C. 30; and Armenia became tributary to the Romans.

About the commencement of the Christian era, Abgarus was king of Armenia. On his death the kingdom was divided between his son Anane and his nephew Sanadroug; but the ambitious Sanadroug expelled Anane, and took possession of the kingdom. Sanadroug was succeeded by the usurper Erowant, an Arsacid by the female line, who made himself master of the kingdom about A.D. 58. He extirpated the family of his predecessor, with the exception of the infant Ardaches, who was placed in concealment, and carried to the court of Persia. When Ardaches arrived at manhood, with the assistance of some of the neighbouring princes he deposed and slew the tyrant, and obtained possession of the kingdom. Ardaches was a brave and martial prince, and conquered the Alani of the Caucasus, and some other races; but his reign was generally tranquil, and he did much to ameliorate the condition of his subjects by the establishment of schools and other useful institutions.

When the Arsacidæ were expelled from the Persian throne (A.D. 226), Chosroes I., surnamed the Great, was king of Armenia. Being allied to the expelled family, he naturally took up arms in their defence; and marching against the usurper Ardashir he defeated him in battle. Chosroes, shortly after, was assassinated by Anag at the instigation of Ardashir, and Armenia became subject to Persia, A.D. 232.

In the massacre of the royal family which ensued, none escaped but Tiridates, a son of Chosroes, who fled to Rome; and afterwards, with the assistance of the Romans, succeeded in establishing himself upon the throne, A.D. 259. The first act of his reign was the persecution of the Christians. St Gregory, surnamed the Illuminator, was cast into prison; but the king being miraculously cured of a dangerous distemper by that saint, he and most of his people embraced the Christian religion. The introduction of Christianity tended to arouse the animosity of the Persians; and from this period Armenia became the theatre of almost uninterrupted struggles between the Romans and Persians, until Theodosius the Great agreed to cede to Persia the eastern part of the country, which was hence called Persarmenia, while the western part was attached to the Roman Empire. Theodosius nominated Arsaces IV., then king of Armenia, governor of the western division; and the Persian king, in order to conciliate the people, appointed Chosroes III., a descendant of another branch of the Arsacidæ, governor of the eastern part. On the death of Arsaces IV. his dominions were conferred on the commander Cazavon; and the rule of the Arsacidæ in Persarmenia ended with Ardasches IV. who was dethroned by the Persian king Bahram V. in 428. From that time Armenia ceased to be a kingdom, and till 632 it was ruled by Persian governors. From the time that the Persians obtained a footing in Armenia they strenuously endeavoured to subvert Christianity, and to establish Paganism in its stead. For that purpose they had recourse to the most cruel persecutions, and frequent insurrections were the consequence. From 632 till 859 Armenia was the scene of almost incessant struggles between the Greeks and Mohammedans, and it became by turns subject to each. At the latter date the dynasty of the Pagratidæ, who had settled in Armenia at an early period, came into power. This family was of Jewish origin, and had risen to be one of the most powerful in that country. Ashod, one of this family, so gained the confidence of the khalif as to be declared king of Armenia in 885, and his title was afterwards recognized by the Greeks. He reigned thirty-one years; and his descendants maintained their authority in Armenia till 1079, when Gagik was treacherously murdered by the Greeks, and the greater part of the country became dependent on the Grecian empire. Koussen, a relative of the late king, founded a small principality in the Taurus Mountains, north of Cilicia, which gradually extended its boundaries to the Mediterranean. The princes of this house allied themselves with the European monarchs in the crusades. This kingdom maintained its independence till the year 1375, when the last king Leon VI. was taken prisoner by the Mamelukes of Egypt. After a captivity of six years he obtained his liberty, and wandered through Europe from one country to another till the time of his death, which took place at Paris in 1393. In 1583 Armenia was overrun by the Ottomans, who treated the people with such cruelty that great numbers of them took refuge in Persia and other countries. In 1604 Shah Abbas made an incursion into Armenia, and carried off a great part of the inhabitants; and from that time Armenia lost every shadow of nationality and independence. The greater part of the country was annexed to Turkey, and divided into pashalics; while the eastern part remained subject to Persia. Since the commencement of the present century, Russia has, from time to time, acquired considerable portions of this territory; and at present Armenia forms the Turkish pashalics of Erzeroom, Trebizond, Diarbekir, Kars, and Van, part of the Persian province of Azerbijan, and the Russian government of Transcaucasia; Mount Ararat being, as it were, the central boundary-stone between them. —See *Historiæ Armeniacæ*, by Moses of Chorene; *Memoires Historiques et Geographiques sur l'Armenie*, par M. Saint Martin; *History of the Vartan*, translated by Neumann; *Journal of the Geographical Society;* Kinneir's *Memoirs of the Persian Empire, and Travels in Armenia;* Ker Porter's *Travels*, &c.

ARMENIAN LANGUAGE. The translation of the Bible by Miesrob is the earliest monument of the Armenian or Haikan language that has come down to us. The dialect in which this version is written, and in which it is still publicly read in their churches, is called the old Armenian. The modern Armenian not only departs from the elder form by dialectual changes in the native elements of the language itself, but also by the great intermixture of Persian and Turkish words which has resulted from the conquest and subjection of the country. It is, perhaps, this diversity of the ancient and modern idioms which has given rise to the many conflicting opinions that exist as to the relation in which the Armenian stands to other languages. Thus Cirbied and Vater both assert that it is an original language, that is, one so distinct from all others in its fundamental character as not to be classed with any of the great families of languages. Eichhorn, on the other hand, affirms that the learned idiom of the Armenian undoubtedly belongs to the Medo-Persian family. Whereas Pott says that, notwithstanding its many points of relation to that family, it cannot strictly be considered to belong to it; and Gatterer actually

classed it as a living sister of the Basque, Finnish, and Welsh languages.

As to form it is said to be rough, and full of consonants; to possess *ten* cases in the noun—a number which is only exceeded by the Finnish; to have no dual; to have no mode of denoting gender in the noun by change of form, but to be obliged to append the words *man* and *woman* as the marks of sex—thus to say *prophet-woman* for *prophetess* (nevertheless, modern writers use the syllable *ouhi* to distinguish the feminine); to bear a remarkable resemblance to Greek in the use of the participle and in the whole syntactical structure; and to have adopted the Arabian system of metre.

Until the third century of our era, the Armenians used either the Persian or Greek alphabet. In the fifth century, however, the translation of the Bible created the necessity for characters which would more adequately represent the peculiar sounds of the language. Accordingly, after a fruitless attempt of a certain Daniel, and after several efforts on his own part, Miesrob saw a hand in a dream write the very characters which now constitute the Armenian alphabet. The 38 letters thus obtained are chiefly founded on the Greek, but have partly made out their number by deriving some forms from the Zend alphabet. The order of writing is from left to right. Miesrob employed these letters in his translation of the Bible, and thus ensured their universal and permanent adoption by the nation. (Gesenius; article *Palæographie,* in Ersch and Gruber.) (J. N.)

ARMENIAN VERSION. The Armenian version of the Bible was undertaken in the year 410 by Miesrob, with the aid of his pupils Joannes Ecelensis and Josephus Palnensis. It appears that the patriarch Isaac first attempted, in consequence of the Persians having destroyed all the copies of the Greek version, to make a translation from the Peshito; that Miesrob became his coadjutor in this work; and that they actually completed their translation from the Syriac. But when the above-named pupils, who had been sent to the ecclesiastical council at Ephesus, returned, they brought with them an accurate copy of the Greek Bible. Upon this Miesrob laid aside his translation from the Peshito, and prepared to commence anew from a more authentic text. Imperfect knowledge of the Greek language, however, induced him to send his pupils to Alexandria, to acquire accurate Greek scholarship; and, on their return, the translation was accomplished. Moses of Chorene, the historian of Armenia, who was also employed, as a disciple of Miesrob, on this version, fixes its *completion* in the year 410; but he is contradicted by the date of the Council of Ephesus, which necessarily makes it subsequent to the year 431.

In the Old Testament, this version adheres closely to the LXX. (but, in the Book of Daniel, has followed the version of Theodotion). Its most striking characteristic is, that it does not follow any known recension of the LXX. Although it more frequently agrees with the Alexandrine text, in readings which are peculiar to the latter, than it does with the Aldine or Complutensian text; yet, on the other hand, it also has followed readings which are only found in the last two. Bertholdt accounts for this mixed text by assuming that the copy of the Greek Bible sent from Ephesus contained the Lucian recension, and that the pupils brought back copies according to the Hesychian recension from Alexandria, and that the translators made the latter their standard, but corrected their version by aid of the former. The version of the New Testament is equally close to the Greek original, and also represents a text made up of Alexandrine and Occidental readings.

This version was afterwards revised and adapted to the Peshito, in the sixth century, on the occasion of an ecclesiastical union between the Syrians and Armenians. Again, in the thirteenth century, an Armenian king, Hethom or Haitho, adapted the Armenian version to the Vulgate, by way of smoothing the way for a union of the Roman and Armenian churches. Lastly, the bishop Uscan, who printed the first edition of this version at Amsterdam in 1666, is also accused of having interpolated the text, by adding all that he found the Vulgate contained *more* than the Armenian version. The existence of the verse 1 John v. 7, in this version, is ascribed to this supplementary labour of Uscan. It is clear from what has been said, that the critical uses of this version are limited to determining the readings of the LXX. and of the Greek text of the New Testament which it represents, and that it has suffered many alterations which diminish its usefulness in that respect. (J. N.)

ARMENTIERES, a small handsome town in the department Du Nord, in France, containing 6675 inhabitants. It was taken in 1667 by Louis XIV., who dismantled it. The river Lys traverses the town, and forms a small harbour. Its principal manufactures are cotton, linen, lace, thread, and sailcloth. Long. 3. 3. E. Lat. 50. 40. N.

ARMIGER, a title of dignity belonging to such gentlemen as bear arms; and these are either by courtesy, as sons of noblemen, eldest sons of knights, &c.; or by creation, such as the king's servants, &c. See ESQUIRE.

ARMILLARY SPHERE. See GEOGRAPHY, *Globes.*

ARMINIANS, a religious sect, which arose in Holland, by a separation from the Calvinists. They followed Arminius, who, thinking the doctrine of Calvin with regard to free-will, predestination, and grace, too severe, began, in the year 1591, to express his doubts concerning them; and upon further inquiry adopted sentiments more nearly resembling those of the Lutherans. After his appointment to the theological chair at Leyden, he thought it his duty to avow and vindicate the principles which he had embraced; and the freedom with which he published and defended them exposed him to the resentment of those that adhered to the theological system of Geneva, which then prevailed in Holland; but his principal opponent was Gomar, his colleague. The controversy which was thus begun became more general after the death of Arminius, in the year 1609, and involved the United Provinces in civil discord. The Calvinists, or Gomarists as they were now called, appealed to a national synod. Accordingly the synod of Dort was convened by order of the States General, in 1618, and was composed of ecclesiastical deputies from the United Provinces, as well as from the reformed churches of England, Hessia, Bremen, Switzerland, and the Palatinate. The principal advocate in favour of the Arminians was Episcopius, who at that time was professor of divinity at Leyden. It was first proposed to discuss the principal subjects in dispute, and that the Arminians should be allowed to state and vindicate the grounds on which their opinions were founded: but some difference arising as to the proper mode of conducting the debate, the Arminians were excluded from the assembly, their case was tried in their absence, and they were pronounced guilty of pestilential errors, and condemned as corrupters of the true religion. In consequence of this decision they were treated with great severity, deprived of all their posts and employments, their ministers silenced, and their congregations suppressed. However, after the death of Prince Maurice, who had been a partisan of the Gomarists, in the year 1625, the Arminian exiles were restored to their former tranquillity; and, under the toleration of the state they erected churches and founded a college at Amsterdam, appointing Episcopius to be the first theological professor. The Arminian system has very much prevailed in England since the time of Archbishop Laud, and its supporters in other countries are numerous.

The Arminians are also called *Remonstrants,* from a humble petition, entitled their *Remonstrance,* which, in the year 1610, they addressed to the states of Holland. Their principal writers are Arminius, Episcopius, Vorstius, Grotius, Curcellæus, Limborch, Le Clerc, and Wetstein; not to mention many others of more modern date.

ARMINIUS, a celebrated German chief. See GERMANY.

ARMINIUS, *Jacobus,* whose real name in Low Dutch was James Hermanni, a famous Protestant divine, was born at Oude Water, in Holland, in 1560. He was ordained minister at Amsterdam on the 11th of August 1588, where he

soon distinguished himself by his sermons, which were remarkable for their solidity and learning. Martin Lydius, professor of divinity at Franeker, judging him a fit person to refute a polemic in which Beza's doctrine of predestination had been attacked by some ministers of Delft, Arminius at his desire undertook the task; but upon thoroughly examining the reasons on both sides, he adopted the opinions he proposed to overturn, and afterwards went still farther than the ministers of Delft had done. In 1600 he opposed those who maintained that ministers should subscribe the confession and catechism every year. During a pestilential disease which raged at Amsterdam in 1602, he acted with the greatest resolution and courage, in assisting the poor and comforting the sick; and Lucas Trelcatius and Francis Junius dying of that disease at Leyden, the curators of that university chose Arminius professor of divinity there. He was afterwards made doctor of divinity. Disputes upon grace were kindled in the university; and he was likewise involved in a new contest occasioned by a disputation of his concerning the divinity of the Son. These contests, his continual labour, and the vexation at seeing his reputation blasted by slanders in relation to his opinions, impaired his health, and threw him into a fit of sickness, of which he died on the 19th of October 1609. Arminius was esteemed an excellent preacher: his voice was low, but very agreeable; his pronunciation admirable; he was easy and affable to persons of all ranks, and facetious in conversation amongst his friends. The curators of the university of Leyden had so great a regard for him that they settled a pension upon his wife and children. His several treatises, collected in a 4to volume, were published at Leyden in 1629, and have been frequently reprinted.

ARMISTICE, in *Military Affairs*, a temporary truce or cessation of arms for a very short space of time. The word is compounded of *arma*, arms, and *sisto*, to stop or cause to stand still.

ARMLET, an ornament which is worn on the upper arm. In the East, bracelets are generally worn by women, and armlets only by men. The armlet, however, is only in use among men as one of the insignia of sovereign power. The Egyptian kings are represented with armlets, which were also worn by the Egyptian women.

ARMORIC, or AREMORIC, something that belongs to the province of Bretagne or Britany, in France. The name *Armorica* was anciently given to all the northern and western coast of Gaul, from the Pyrenees to the Rhine, under which name it was known even in Cæsar's time. The word is of Bas-Breton origin, and signifies *maritime;* compounded, according to M. Menage, of *ar*, upon, and *môr*, sea.

ARMORY, a storehouse of arms, or a place wherein military habiliments are kept ready for use. There are armories in all arsenals, citadels, castles, &c.

ARMOUR, a defensive habit, wherewith to cover and secure the body from the attacks of an enemy. In ancient statutes this is frequently called *harness*. A complete armour anciently consisted of a casque or helm, a gorget, cuirass, gauntlets, tasses, brassets, cuisnes, and covers for the legs, to which the spurs were fastened. This formed armour *cap-à-pié*, and was used by the cavaliers and men-at-arms. The infantry had only part of it, viz., a pot or head-piece, a cuirass, and tasses; but all light. Lastly, the horses themselves had their armour, wherewith to cover the head and neck. Of all this furniture of war, scarce anything is now retained except the cuirass and helmet; the gorget or neck-piece, which was latterly a mere ornament, and of no defence, being no longer used.—See Meyrick's *Ancient Armour*.

ARMS, ARMA, in a general sense, includes all kinds of weapons, whether for defence or offence. See ARMY.

ARMS, or *Armories*, in *Heraldry*, marks of dignity composed of certain figures and colours, and borne on banners, shields, &c., for the distinction of persons, families, and states. See HERALDRY.

ARMSTRONG, JOHN, M.D., a physician, poet, and miscellaneous writer, the friend of Thomson, Mallet, and Wilkes, was born about the year 1709, in Castletown parish, Roxburghshire, where his father and brother successively were ministers of the Scottish church. He completed his education at the University of Edinburgh, where he took his degree in Physic, Feb. 4. 1732, with much reputation. His professional success, however, does not seem to have been at any time considerable, as he probably paid more attention to literary than to medical labours. He took up his residence in London, and in 1746 was appointed one of the physicians to the Hospital for lame and sick soldiers behind Buckingham House. In 1760 he was appointed physician to the army in Germany, which appointment he held till the peace of 1763. In a poetical epistle to John Wilkes in 1761, he drew upon himself the enmity of the satirist Churchill, and afterwards quarrelled with Wilkes himself. His latter years seem to have been embittered by disappointments, as is evinced by the tone of his writings, in which he particularly directs his sarcasms against his medical brethren and the reviewers. He died in 1779, and was found, notwithstanding his want of professional success, to have saved upwards of L.3000.

Dr Armstrong's first publication was a humorous pamphlet, entitled *An Essay for Abridging the Study of Physic, &c.*, containing much clever and well-directed satire. It appeared anonymously in 1735. Of his numerous subsequent essays, sketches, and poems, the only one by which he is now remembered is his didactic poem, entitled *The Art of Preserving Health*, first published in 1744. As a poetical composition, its value is but small. It contains, however, some passages of considerable merit; and, considering the nature of the subject, is perhaps as successful a performance as could have been expected. His smaller pieces, including *Benevolence*, a poetical epistle; *Taste*, an epistle to a young critic; *Sketches by Launcelot Temple, Esq., &c.*, were published along with the *Art of Preserving Health*, in 1770, under the title of *Miscellanies*. They generally display much humour and acuteness of observation.

ARMSTRONG, *John*, M.D., an eminent physician and medical writer, was born in 1784, at Bishop Wearmouth in Durham. Having received some preliminary education, he completed his studies at the University of Edinburgh, where he obtained his medical degree in 1807. He then became a candidate for practice in his native place, but soon afterwards removed to Sunderland, where he engaged in extensive practice, and became physician to the dispensary in that town. This situation he resigned in 1817, and settled in London, where the reputation he had already acquired by his writings prepared the way for his future success. As a lecturer, also, in the Webb Street School at London, Dr Armstrong was highly popular. His lectures, edited by Joseph Rix, were published in 1834 in one volume 8vo. His principal work is that entitled *Practical Illustrations of Typhus Fever and other Febrile and Inflammatory Diseases*, which was published in 1816. Dr Armstrong died of pulmonary consumption in 1829. He is represented as a man of estimable character,—yet it is to be regretted that he had the temerity to depreciate such men as Mead, Cullen, and Heberden; though their reputation indeed, stands too high to be affected by such criticism.

ARMUYDEN, a seaport town of the United Provinces, in the island of Walcheren, formerly very flourishing, but now inconsiderable. Pop. 1340. Long. 3. 40. E. Lat. 51. 30. N.

ARMY.[1]

Army.

Definitions.

An army, says Dr Johnson,[2] is "a collection of armed men obliged to obey one man." This definition, however, has little else than its brevity to recommend it. An army, it is true, is "a collection of armed men," and such a "collection" is generally "obliged to obey one man," that is to say, it is commonly placed under the exclusive control and direction of an individual chief or leader. But it does not follow that "a collection of armed men obliged to obey one man" is the distinguishing or principal characteristic of an army, since a gang of robbers or banditti would equally answer this description. To be at all applicable, therefore, the definition of army must be at once more comprehensive and more precise; in other words, it must include the specification of those peculiar circumstances or attributes, the aggregate of which constitutes the complex idea sought to be resolved. Hence an army may, we think, be more accurately defined, a certain portion of the community selected, raised, or assembled, for the defence of the state, by means of conscription, voluntary enrolment, tenure of military service, or otherwise; armed, disciplined, and organized, conformably to a given system, which is considered best calculated for giving full development and efficacy to its collective force; and commanded by a chief or leader, with subordinate officers in regular gradation, to carry his orders into effect, and move the living machine, thus constructed, as he shall think proper to direct. It is an artificial or scientific combination of a great number of powers, individually small or insignificant, so as, by their union and concentration, to accomplish mighty and important deeds; a force which states and nations create out of the elements of their strength, as mechanicians form engines by taking advantage of and skilfully combining the action of the primary mechanical powers; an instrument, in short, so contrived as, though originally intended for the best, to be equally available for the worst purposes, being alike fitted for defence or aggression, for protection or conquest, for restraining and punishing the dishonest ambition of others, or affording the means of gratifying our own. An army, therefore, may be considered a species of movable engine, composed of a vast number of individual parts or powers, so arranged and organized as not only to act in concert, but to exert their whole aggregate force in any direction and upon any point which may be ordered or required. At the present day this denomination is applied to any given number of soldiers, consisting of artillery, infantry, and cavalry, of various descriptions, all completely armed and provided with engineers, a train of artillery, ammunition, magazines, commissariat, and other necessary adjuncts, subject to the command of a general, having under him lieutenant-generals, major-generals, brigadier-generals, colonels, majors, captains, and subalterns:[3] And an army is now composed of battalions or squadrons, regiments, brigades, divisions, and sometimes corps d'armée; two or more battalions or squadrons forming a regiment, two or more regiments a brigade, two or more brigades a division, and two or more divisions a corps d'armée. So much for definition and description.

General observations.

Were we called upon to trace to its origin the history of war, we should find it necessary to ascend through every form and gradation of society to the very cradle of the human race. Admitted on all hands to be one of the greatest evils, war is also, unhappily, one of the oldest. "Il est triste d'imaginer," says a celebrated military writer, "que le premier art qu'aient inventé les hommes, ait été celui de se nuire, et que, depuis le commencement des siècles, on ait combiné plus de moyens pour détruire l'humanité que pour la rendre heureuse."[4] This is a truth which cannot be disputed. The passions of rivalry, jealousy, hatred, revenge, cupidity, thirst of power or ambition, were born with the world; and these, in their turn, gave birth to war, which again produced the desire of conquering or combating with success. But, in proportion as this desire came to prevail, men would naturally be led to reflect as to the means best fitted to insure its gratification: and as experience must soon have convinced them that the battle was not always to the strong, nor the race to the swift,—or, in other words, that mere brute force, openly applied, was in many cases insufficient to secure the victory, and, in most, productive of a loss that countervailed it,—they must early have discovered that some degree of combination was requisite, and certain extrinsic qualities necessary, to render it effectual; that violence might find an auxiliary in cunning, and resistance be paralysed by stratagem and surprise. Such, accordingly, is the state of things which generally obtains amongst savage tribes, however warlike and enterprising. They seldom go down to battle openly and boldly; nor do they consider victory, when dearly purchased, as either honourable or desirable. Artifice is their main resource. The first principle of their simple tactics is to steal unperceived upon the enemy, and overwhelm him, while unsuspicious of attack and unprepared for resistance. In this and similar principles, however, we discover the origin and primary development of the military art. Its source is in the forest or the wilderness. But as war is the first art which men invented, so it is also that which was soonest cultivated and improved. It kept pace with the progress of society;—as mankind multiplied, and communities extended themselves, it received a corresponding expansion;—more means were combined, and a greater number of men were assembled. This was the second stage of the art, where it remained long stationary, and in nearly the same state in which we find it at the present day among some of the Asiatic nations. Science had not digested nor systematized the rude and shapeless mass of knowledge which experience had supplied, or suggested new combinations of existing means. But ambition at length gave a fresh stimulus to improvement, by opening up a new theatre for its expansive energies; and successive conquerors contributed largely to the cultivation of an art which became the instrument of their glory. In their hands, accordingly, it determined the destiny of nations;—it raised up or destroyed empires;—it produced mighty revolutions;—it overthrew old dynasties, and created new ones in their stead;—and, amidst all the havoc and desolation occasioned by the pursuit of false glory, it contributed, upon the whole, to the cultivation of those sciences and arts which have a tendency to mitigate the natural ferocity of man, and ultimately to render conquest itself less destructive, and war less sanguinary.

Army.

---

[1] The important changes effected in the organization and establishment of the British army since the war of 1854, have of course deprived the following article of the strict accuracy which it originally possessed. As these improvements are still in progress, moreover, and are likely to continue for some considerable time, it has been found impossible to make the details respecting the British army in all respects as accurate as could be desired. (*Note* of 1858.)

[4] *Essai Général de Tactique*, par Guibert, vol. i., p. 59, *Disc. Prélim.*, Paris, 1803.

Results so vast leave no doubt whatever, that the art which was principally instrumental in producing them, must have made considerable progress at a very remote period of the world. It is in fact in the early and semi-barbarous stage of society that the military virtues are found in the greatest perfection. The mind is then fierce, ardent, energetic, and daring; peculiarly accessible to the illusion of warlike renown, and undistracted by any of those influences or impressions which act so powerfully upon man in civilized life; while the body, unpampered by luxury, unenfeebled by indulgence, is a fit companion for such a spirit, and capable of enduring, without difficulty, the fatigues and privations incident to war. Add to this that, at the period of which we speak, the only law generally recognised and respected is the law of the strongest; that the necessity of self-defence, of protecting person and property from violence and spoliation, keeps men continually prepared to repel force by force, or to retaliate one aggression by another; that, consequently, the disorders which distract society re-act upon and foster the turbulent spirit in which they have their origin; that war thus becomes a trade which all are either disposed or compelled to pursue; that, to bold and adventurous spirits, it opens up the only path which leads to fortune and to fame, and thus holds out irresistible temptations to embark in military enterprises. At such a period all men are soldiers, and war is their natural employment; in it they live and move and have their being. But necessity is the parent of invention, and the mother of arts; and to it the science of war was indebted for its first improvements. Armies are unwieldy machines, which cannot be moved without some degree of organization, nor supported without considerable care and foresight, nor led into action with an enemy without a certain knowledge of tactical combinations. It is obvious, therefore, that wherever we read of such masses of men having been assembled, whether for purposes of aggression or defence, we may safely consider this fact as of itself conclusive, that the military art had there reached the second stage of its progress, or, in other words, had made considerable advances. History may be silent as to the precise extent to which improvement had been carried, and the records of the past may afford no clue to direct our inquiries concerning the composition and organization of the armies of remote antiquity; but if it be once admitted that such armies existed, and that they defended some countries and overran or conquered others, this admission will imply no inconsiderable knowledge of the art of war on the part of those by whom they were organized and directed. Discipline of some kind or other is the bond which keeps together large bodies of men: without it they are a mere mob or rabble, incapable alike of action or direction, and formidable to none save the people of the country where they happen to have congregated. Even the Tartar hordes of Genghis Khan and Timour had an organization and discipline of their own, by means of which these barbarian conquerors were enabled to impel their fierce and warlike masses against the enfeebled and effeminate soldiery of countries advanced in wealth and in civilization;[1] and the same observation applies still more forcibly to the Asiatic and Turkish armies of our own time. In a word, we may adopt with some qualification the remark of Guibert, when speaking of the progress of the military art: "Il précéda," says he, "chez tous les peuples, les arts et les sciences, et y périt à mesure que celles-ci s'étendirent."[2] The details into which we are about to enter will fully illustrate the truth of these general observations.

Ancient Egyptian army.

The earliest military establishment of which history has preserved any record is that of Egypt under the reign of Sesostris, or, as he is denominated in the monumental sculptures of that wonderful country, Rhamses;[3] who was considered the greatest of the Egyptian kings after Osiris,[4] and has generally been supposed by chronologists to have flourished about seventeen centuries before our era.[5] But Osiris was an ideal being, the offspring of mythology, and the hero of fable, adored by the Egyptians sometimes as a deified mortal, sometimes as a personification of the Nile, and sometimes as the symbolical representative of the solar orb. Sesostris, on the contrary, is claimed by history as a real personage; and although the accounts which have been preserved of the reign of this prince, chiefly by the Greek historians, are dashed with a considerable admixture of exaggeration and romance, we cannot reasonably doubt the existence of the monarch, however we may be inclined to question the exploits of the hero and the achievements of the conqueror. The substance of these accounts, indeed, when considered in connection with the corroborative evidence supplied by the Egyptian monuments, and the traces of his expedition which remained even in the age of Herodotus, may be regarded as the more deserving of credit that, while scepticism has little to oppose to them except its own incredulity, the statements of the Greek historians are not only consistent with one another, but in strict accordance with the uniform tradition and belief, as well as with the records, of that country, the mother of arts and civilization, which, under this renowned

[1] Timour or Tamerlane, of whom unfortunately we know so little, has left an institutional or elementary treatise on war and the art of conducting armies, each page of which affords proof of a natural genius for commanding men, as well as of tact and skill in employing them to the best advantage. See *Instituts de Timour*, par Langlès; also Jomini, *Traité des Grandes Opérations Militaires*, tome viii. p. 678. Paris, 1616.

[2] *Essai Général de Tactique*, vol. i. p. 60.

[3] One of the difficulties which occur in our inquiries concerning Sesostris arises from the different names by which he has been designated by ancient writers. He has been variously called Sesostris, Sesoosis, Sesochis, Sesonchosis, Sethosis, Sethos, Ramesses, Rameses, Rhamses, Ramestes, Rampses, Vexores, and Ægyptus. But most of these appellations were probably titular. Thus, *Sesostris* may be SE-SIOS-T-RE, which signifies, *filius domini, donum solis*; *Sesoosis* may, in like manner, be a corruption for SE-SIOS-SIOS, *filius domini dominorum*; and *Rhamses* or *Ramesses*, derived from RE, *sol*, and MES, *gignere*, may signify *Begotten by the Sun*. But it is not always possible to render ancient Egyptian names according to the grammatical rules established in the Coptic language, and, therefore, such etymologies as those now proposed are to be received as purely conjectural. The common designation of this monarch on the monuments is RAMESES-MEIAMOUN, *Rhamses beloved of Ammon*; or, adopting the etymology of *Rhamses* just proposed, *Begotten by the Sun, Beloved of Ammon*; in which case both appellations would be merely titular. *Vide* Sir W. Drummond's *Origines*, book iv. chap. 13, and Champollion's *Précis du Système Hiéroglyphique*, p. 223. Paris, 1824.

[4] Manetho *apud Euseb. Chron.* lib. i. In Manetho *apud Josephum contra Appionem*, lib. i. p. 1053, this monarch is indifferently called *Ramesses* and *Rampses*.

[5] Chronologists have been unable to fix the precise date of the reign of Sesostris. Larcher, the celebrated translator of Dionysius of Halicarnassus, adopts and defends with much warmth the chronography of Herodotus; while others, rejecting the authority of the father of history, endeavour to determine the era of the Egyptian monarch from the scanty data furnished by Diodorus and Strabo. The objections to the conclusions of Larcher, stated by Sir William Drummond in his *Origines*, book iv. chap. 13, appear to be perfectly unanswerable.

sovereign, is supposed to have reached an unprecedented height of military glory.

Sesostris, however, did not create the military spirit to which he appears afterwards to have given such ample development. This was in a great measure the work of his father, Amenophis III., who, shortly after the birth of his son, is said to have assembled all the male children born on the same day, and to have given them the same education. No distinction was made between the young prince and his companions. They were alike engaged in the same studies, trained to the same exercises, inured to the same hardships, and instructed in the use of the same arms. A rigid discipline prescribed unremitting exertion, while daily privations and fatigue hardened and prepared them for the duties of war. In establishing this military seminary, Amenophis appears to have intended placing around his son a faithful band of soldiers, attached to him by the associations of early friendship, and the ties of brotherhood in arms. Nor did the result disappoint his expectations. Arrived at manhood, the prince and his companions soon evinced how much they had profited by their education,—how well they merited the confidence reposed in them. With bodies rendered vigorous and athletic by labour and exercise, and with minds cultivated by the best studies, they were already fitted to act both as soldiers and as generals, to serve with energy, or to command with skill. Sent by his father at an early age to command an expedition against the Arabians, the prince, accustomed, as well as his companions, to suffer long both from hunger and from thirst, could meet upon equal terms the wandering and yet unconquered tribes, who chiefly trusted for their defence to the barrenness of their inhospitable deserts. Arabia was subdued and annexed to the Egyptian monarchy. He afterwards directed his march to the west, and his father lived to see the greater part of Libya conquered by his victorious son. When Sesostris mounted the throne, therefore, his military fame was established. The qualities of his mind, his dauntless courage, and his daring ambition, seemed to be announced by his personal appearance; and the people, no doubt, easily associated the character of the hero with the robust frame and gigantic stature[1] of their new monarch. But it is more material to state, that the success of his arms, in his wars with the Arabians and Libyans, had inspired him with the hopes of making yet more extensive conquests; and, if we may credit the Greek historians, the perilous project of subjugating the world must have been already familiar to the mind of Sesostris when he succeeded to the crown. Amidst the burning sands of Libya, and in the depth of the Arabian deserts, the phantom of universal empire showed itself, and he vowed to pursue it.[2]

His resolution being thus taken, no time appears to have been lost by the new sovereign in preparing his subjects for an enterprise, which could not be undertaken but in defiance of all the counsels of prudence. He caused various reports to be spread abroad, artfully attributing his project to other causes than his own ambition. His daughter Athyrtis, famed for her wisdom, as a sort of Egyptian Cassandra, proclaimed the facility with which her father would conquer the earth: the success of the enterprise was prognosticated by omens, by sortilege, and by divination: and the people were reminded that, at the birth of Sesostris, Phtha had appeared to his father in a dream, and had predicted to Amenophis that the new-born boy should one day become master of the world.[3] Nor did the Egyptian king content himself with influencing opinion in his favour by means of prophecies, prodigies, and visions. His natural sense taught him that other and more rational precautions were necessary; that a king who is not popular at home, should not think of making conquests abroad. His first object, therefore, was to secure the affections of the Egyptians: and for this purpose he employed all those arts which, exercised by sovereigns, are so powerful in conciliating popular favour. Some he won by his munificence, others by his clemency; the selfish were secured by his liberality, the vain were flattered by his condescension and affability; even traitors to the royal authority were allowed to escape with impunity, and public debtors were liberated from the prisons in which they were confined.[4] On the other hand, that he might provide for the tranquillity of his kingdom, and leave none behind him who either would or could attempt a revolution in his absence, he made a partition of power among the chief men of the nation, dividing the whole territory of Egypt into thirty-six nomes or prefectures, over which he appointed as many governors, each of whom was charged with the collection of the royal revenues, and the administration of the laws within his own particular district. He at the same time elevated his brother Armais to the rank of regent of the kingdom; and, except that this prince might not wear the royal diadem, he was permitted to assume all the pomp of a monarch; an indulgence which he so far abused as to usurp the crown in the king's absence, and to attempt his life on his return home from his long and perilous expedition.[5]

Having completed these and other necessary arrangements, Sesostris next proceeded to raise an army. The peace establishment of the kingdom, as previously organized by this prince, appears to have consisted of a numerous militia, divided into two classes, denominated *kalasires* and *harmatopoii*, and amounting, according to Herodotus, to 410,000 men, distributed throughout the different provinces as a species of military colonists, each man being allowed a portion of land adequate to the maintenance of himself and family. This formed the nucleus of the mighty force which Sesostris now raised for the conquest of the world, consisting, if we may believe Diodorus Siculus, of 600,000 infantry, 24,000 cavalry, and 27,000 war chariots; a force certainly equal to the magnitude of the enterprise in which he was about to engage, though it is difficult to conceive how the population of a small country like Egypt, supposing it ever so dense, could have supplied so vast a body of men, exceeding, by more than 200,000, the numerical strength of the army with which the Emperor Napoleon invaded Russia, and which was by far the largest ever assembled in modern times. No precise information has reached us as to the composition, organization, and discipline of this expeditionary army. We only learn, incidentally as it were, that the king chose as the leaders of his less experienced troops, the companions of his youth, trained, like himself, to the use of arms, and exceeding 1700 in number; that disgrace or infamy was attached to disobedience of orders and neglect of duty, and that meritorious or valorous deeds were liberally rewarded; circumstances which, taken in connection with the particulars above stated, seem to warrant the conclusion, that the military system of Egypt had reached no small degree of improvement, and that the science of war, in all its branches, had made considerable advances. With

Army.

a view to the ulterior objects of the expedition, Sesostris also collected or fitted out a fleet of 400 sail; and the ships are said to have been of large dimensions, adapted to the purposes both of war and transport.[1]

With these immense preparations the warlike monarch at length commenced his perilous enterprise. He invaded Ethiopia, and compelled the inhabitants to pay him a tribute in ebony, gold, and ivory. Even the ferocious Troglodytes yielded to the conqueror. Advancing farther to the southward, he passed the frontiers of Ethiopia, and entered the country extending beyond Sennaar to the Mountains of the Moon, where he left various monuments both of his power and of his piety. In the Straits of Dira or Babelmandeb he joined his fleet, consisting, as above stated, of 400 sail, which had already compelled the inhabitants of the islands in the Erythrean Sea, and of the adjacent continent, to acknowledge his authority. The victorious monarch next proceeded to India, which he completely overran, extending his conquests beyond the Ganges, and subduing some of the countries which lie between that river and the Eastern Ocean. He then directed his course towards the country of the five rivers or Punjab; crossed the immense reticulation of streams, which ultimately unite their waters with the Indus; and ascended the table-land of central Asia. Nor were the Scythian nations able to resist the torrent as it rolled westward through Tartary, behind the mountains of Imaus, and north of the Caspian, to the river Tanais and the Palus Mœotis. Having entered Europe, Sesostris passed through Sarmatia, Dacia, and Mœsia, nor halted until he arrived in Thrace, where he erected columns to perpetuate the memory of his victories, and to prove the extent of his conquests. From Thrace he crossed over into Asia Minor, and advanced into the plains of Colchis (rendered so famous in Grecian story by the expedition of the Argonauts and the fable of the golden fleece), where he founded a colony on the banks of the Phasis, and erected monuments, some of which were in existence in the age of Herodotus. He then marched against the Assyrian empire, which he conquered, and thus seated himself on the throne which had been occupied by Ninus and Semiramis. Finally, surrounded with the trophies of victory, and enriched with the spoils of nations, Sesostris returned to Egypt in triumph, after having been thirty years engaged in an expedition, undertaken in defiance of all the dictates of prudence, yet, if we believe the concurrent testimony of historians, terminated without a single reverse of fortune.[2] Such is the military story of the renowned Rhamses.[3] That it involves many improbabilities is obvious; but what portion of ancient history is free of them? Mankind, in every age of the world, have taken delight in the marvellous; and if the ancients appear to have been pleased with reading romances in history, the moderns seem equally disposed to read history in romances. The great difficulty in forming an accurate judgment as to the story of the Egyptian monarch arises from the total want of details. We hear nothing of the generals to whom he was opposed, of the cities which he besieged, nor even of the battles which he fought. Historians relate his triumphs, but are silent respecting the skill which obtained them. At the same time, it cannot reasonably be doubted, we think, that there is a large substratum of truth in the narratives which have reached us respecting this extraordinary personage. By the concurrent testimony of the ancient authors, confirmed by the evidence derived from the Egyptian monuments, he is represented as a great warrior and conqueror; as the first, and, we may almost add, the last, of the Pharaohs who pursued the phantom of military renown, and sought for glory in distant expeditions: nor are there wanting circumstances which warrant the conclusion, that he overran some countries, conquered others, and left traces of his progress in many parts both of Asia and Europe. That he established a regular army, and provided a fleet to co-operate with it in his expedition against the countries of the East, are facts which seem to be as well attested as any in ancient history.[4]

Persian armies.

" C'est chez les peuples d'Asie, chez les Perses surtout," says Guibert, " que l'art de la guerre commença à prendre quelque consistance;" but he adds, " après la mort de Cyrus, le luxe lui fit quitter la Perse, et il passa chez les Grecs."[5] This remark, however, must be taken with some important qualifications. As a general proposition, it is doubtless true that the military art first assumed consistence among the Asiatic nations, particularly the Persians; for the warlike spirit of Egypt seems to have expired with its first and only conqueror. But it is utterly absurd to maintain that the death of Cyrus was productive of any change in the military system of Persia, or that this event led to the transference which Guibert has so gratuitously supposed. Cyrus, in as far as we are able to distinguish his character, and form a judgment

[1] *Origines, ubi supra.*

[2] Diodorus, lib. i. sect. 54 and 55; Strabo, lib. xvi.; Herodotus, lib. ii. c. 103 and 110; Manetho *apud Joseph. contr. Apion.*; Julius Africanus *apud Syncellum.* In all the countries through which he passed, Sesostris left monuments behind him; and where he encountered serious resistance, the columns he erected bore this inscription: " Sesoosis, King of Kings, and Lord of Lords, has subdued this region by force of arms." Diodorus, *ibid.*

[3] The information given to Germanicus when he visited the ruins of Thebes, by some of the elder Egyptian priests, relative to this monarch, and the military establishment he had created, is thus recorded by Tacitus in the second book of his Annals: " Mox (Germanicus) visit veterum Thebarum magna vestigia; et manebant structis molibus litteræ Ægyptiæ, priorem opulentiam complexæ; jussusque e senioribus sacerdotum patrium sermonem interpretari referebat habitâsse quondam *septingenta millia* ætati militari: atque eo cum exercitu regem RHAMSEN Libya, Æthiopia, Medisque et Persis, Bactriano ac Scytha potitum; quasque terras Suri Armeniique et contigui Cappadoces colunt, inde Bithynum, hinc Lycium ad mare imperio tenuisse," &c. The strength of the army of Sesostris, as here stated, very nearly coincides with the amount given in the text, on the authority of Diodorus. According to the latter, this army consisted of 600,000 infantry, 24,000 horse, and 27,000 armed chariots; which, as at least *three* men fought in *one* chariot, would make a total of 695,000 men, or only 5000 less than the number reported by the priests to Germanicus on the faith of the monuments.

[4] *Origines, ubi supra.* " It would be in vain," says Sir William Drummond, " to deny to the traditions of ages, to the records of history, and to the authority of monuments, that Sesostris must have been one of the greatest princes that ever lived; while we may fairly confess our doubts of the extent of his conquests, and acknowledge that we cannot ascertain at what period he flourished. The existence of the monarch we may consider as certain; and some of the achievements of the conqueror we may admit to be probable, though we cannot fail to perceive, that the number of his triumphs has been amplified by exaggeration, and the history of his reign crowded with fictions. It is known that the great Ramesses or Ramestes created at least one obelisk, on which he announced himself to be loved and gifted by all the gods of Egypt; but it may be questioned whether he had a right to call himself the master of the whole habitable world. We may believe that Sesostris obtained many victories, and subdued many regions; while we may still avow that we are unable to tell when this mighty monarch reigned, where were the limits of his empire, what humbled nations bowed down before his throne, or what captive kings were yoked to his triumphal car."

[5] *Essai Général de Tactique*, vol. i. p. 61.

of his achievements, appears to have been a wise prince, a warlike monarch, and a great conqueror;[1] while the victories achieved by the Persians under his command, contrasted with the fatal reverses which they afterwards experienced, may induce superficial observers to imagine that the knowledge of the art declined after the hero's death. No opinion, however, can possibly be more erroneous; except, indeed, it be that which represents the Greek tactics as having been primarily derived from the Persian, to which, as will appear in the sequel, they bore not the slightest resemblance. The qualities of the Persian troops may, perhaps, have deteriorated, and, under the influence of luxury and refinement, the military character of the nation may have declined; but the system of organising armies and making war continued, in a great measure, unchanged: nor, as far as the military art is concerned, would it be easy to discover any material difference between the tactics of Cyrus, who was uniformly victorious, and those of Xerxes, Mardonius, and Darius, who experienced the most disastrous defeats. It should also be remembered, that the former led Asiatics against Asiatics, and that the nations he subdued were among the most effeminate and voluptuous of the ancient world: whilst the latter were called to contend with the Greeks in their best days, when their bodies were robust, their hearts strong, and their discipline admirable; and when their armies were commanded by men fired alike with the love of liberty and of glory, and not only conversant with the science of war, theoretically considered, but eminently skilful in all those resources which neutralize superiority of numbers, and enable handfuls of men to snatch the victory from masses apparently overwhelming and invincible.

The strength of the Persian army consisted in its cavalry, which was always of excellent quality, and capable of achieving great things had it been properly commanded. This was emphatically evinced at the passage of the Granicus, where its gallant conduct attracted the admiration of every officer in the Macedonian army, from the king to the humblest dilochite in the ranks.[2] Notwithstanding the absurd principle upon which it was formed, and the total want of support, owing to the treachery or terror of the Greeks in the pay of Darius, who had been brought forward to sustain it, this cavalry bravely disputed the passage; drove Ptolemy, who commanded the vanguard of the Macedonian army, back into the river; charged the heads of the columns as they successively ascended the bank in order to deploy, with the utmost impetuosity; and maintained the combat until it was attacked by the formidable phalanx in front, and by the light infantry on both flanks, when it was at length forced to retire.[3] The Persian infantry had none of the qualities for which the cavalry was distinguished, and seems, in fact, to have been little better than a military mob, without coherence or solidity; while the vast numbers of this arm which were commonly brought into the field impeded the action of the cavalry, which they were incapable of supporting, and served only to create confusion, and supply food for the slaughter, when opposed to disciplined armies commanded by men conversant with military combinations. Marathon, Platæa, and Mycale, all bear witness to the truth of this observation. The war-chariots formed another source of disorder and weakness. Their number, like that of the infantry, was excessive; and as these vehicles could only act upon level ground, they were altogether useless and unavailing in a broken country, or against a skilful commander. With regard to the numerical strength of the Persian armies, we have no precise information, and can only form a conjecture from the statements, almost always exaggerated, of the Greek historians as to the numbers actually brought into the field. Xerxes, who had taken by descent a hereditary hatred of the Greeks, invaded Europe, it is said, and entered Greece at the head of an army, which, with its retinue of servants, eunuchs, and women, amounted to upwards of 5,000,000 of souls; a statement which, if true, would imply that the Persian nation had risen *en masse* to overrun the countries of the West. Yet this vast multitude, or rather horde, was arrested in its progress by 300 Spartans at the pass of Thermopylæ; and that mountain gorge would have become the scene of its total defeat and destruction, had not a base Trachinian betrayed this devoted band of heroes, and enabled the Persians to attack it at once in the front, the flank, and the rear. At Marathon, Datis and Artaphernes, lieutenants of the Great King, brought into the field 100,000 foot and 10,000 horse,[4] which were beaten by 10,000 Athenian infantry and 1000 Platæan auxiliaries, commanded by Miltiades. At Platæa, the Persian force, consisting in all of 300,000 men, was again defeated with great loss by a handful of Lacedæmonians and Athenians under Pausanias. And at the battle of Mycale, fought on the same day with that of Platæa (22d September 479 B. C.), 100,000 men, the wrecks of that portion of the army more immediately under the command of Xerxes, which had just returned from the unsuccessful expedition to Greece, were completely overthrown and dispersed by a small body of Greeks, who stormed their entrenched camp, slaughtered several thousands, and carried off an immense booty. On comparing these various numbers, and making due allowance for casualties, it would appear that the Persian monarch must have entered Greece with about 600,000 fighting men; an enormous force numerically considered, but not too great to provoke incredulity, when we reflect on the mode in which the eastern nations have always made war, and further take into account the circumstance, that nearly the whole of one reign and part of another were consumed in making preparations for this ill-fated expedition.

Of the state of the Persian army in the reign of Alexander, Arrian has furnished us with many important particulars, especially in his account of the battle of Arbela, which is the more interesting, as it gives us some insight respecting the Persian tactics under the last Darius. According to this writer, who had consulted the memoirs of Ptolemy, one of Alexander's generals, but who, nevertheless, seems to have possessed the Greek talent for exaggerating numbers, the army which Darius brought into

[1] The achievements of Cyrus, like those of Sesostris, have been so exaggerated by historians, and embellished by fabulists, that almost every grain of truth has to be separated from a bushel of fiction. The Cyropædia is merely a philosophical romance, with no more of truth or fact in it than is sufficient to give verisimilitude to the story.

[2] The Persian cavalry, 30,000 strong, was, on this occasion, commanded by Memnon, who drew it up in a single line of equal extent with that occupied by the Macedonian army on the other bank of the river. The ground on which it was posted sloped gradually towards the bank of the Granicus, which was here steep and difficult, and hence no position could have been chosen more favourable for the effective action of such a force. But its energies were paralysed, or, which comes nearly to the same thing, its full capabilities were never brought into play, in consequence of its linear formation, which admitted only of detached efforts, without *ensemble* or support. (Guischardt, *Mémoires Militaires sur les Grecs et les Romains*, tom. i. p. 251–258. Lyons, 1760.)

[3] Guischardt, *ubi supra*.

[4] The total number of Persians engaged at Marathon was, according to Valerius Maximus (l. v. c. 4), 300,000; according to Justin (l. ii. c. 9), double this amount, or 600,000 men. No attention whatever is due to such extravagant exaggerations.

Army.

the field on this occasion consisted of 1,000,000 infantry, 40,000 cavalry, 200 chariots armed with scythes, and 15 elephants; a statement which appears equally incredible, whether we regard the absolute amount here assigned, or attend to the glaring disproportion between the relative numerical strength of the different arms. Quintus Curtius, who reduces the infantry to 600,000, and raises the cavalry to 145,000, exaggerates at least with method, and thus avoids an objection fatal to the numerical accuracy of the military historian. The disposition of this enormous force, as described by Arrian, shows the incongruous elements of which it was composed. According to the custom of the Persians, the king placed himself in the centre, having around him his relations and the officers of his court, with his ordinary guards, foot and horse, which sometimes amounted to 15,000 men. These he supported by a body of Greeks in his pay, upon whom he placed great reliance, and by other *corps d'élite* furnished by the native army. The Persians, the Susians, and the Candusians composed the left; on the right were the Syrians, the Assyrians, and other nations, subjects or allies of Persia; and the whole was formed into squares or masses of prodigious depth, evidently with the intention of resisting the compact formation of the Macedonian phalanx, of which the Persians had already had woeful experience. These different nations were variously armed, some with missile weapons, others with pikes, hatchets, maces, &c.; and cavalry were stationed in the intervals between the squares. The reserve was composed of those for whom no place could be found in the first line; and being drawn up too close to it, served only to augment the confusion. The infantry of the left was flanked by the main body of the Persian cavalry, and part of that of the Bactrians; together with two corps, one Scythian and the other Bactrian, a little in advance. On the right, the Armenian and the Cappadocian cavalry were posted in a similar manner, though not in equal force. Two hundred armed chariots were drawn up before the left, and fifty before the right of the infantry, while the elephants and fifty more chariots were placed in advance of the centre.[1] Such was the disposition of the army of Darius on this memorable and decisive day. It was doubtless bad in many respects, particularly in the disproportionate crowding of all arms on the centre and left, while the right was left comparatively weak and uncovered; but its greatest defect, inseparable, perhaps, from the heterogeneous composition of the army, consisted in this, that the defeat of any one part of the line was certain to throw the whole into irretrievable disorder, and to end in a complete rout. Still it showed very considerable knowledge of the military art; while the battle which followed, and which was bravely contested, is even yet considered a study for tacticians.

The Greek armies.

From the earliest times, the genius of the Greeks, adventurous and free, inclined them to war. This, at first a consequence of their position, became in time an attribute of the national character, and gave rise to institutions which, in their turn, served to diffuse and confirm the spirit in which they had originated. Divided into a number of petty states, which were separated often by imaginary boundaries, and naturally jealous of one another, Greece was a scene of never-ending contention, and the theatre of almost continual war. New causes of difference, in the shape of injuries, encroachments, or insults, real or imaginary, were incessantly arising; and as each state was alike proud of itself, suspicious of its neighbours or rivals, and, above all, watchful of its independence, the wrong done, or believed to have been done, was promptly followed by retaliation, which again provoked a repetition of the offence, and thus led ultimately to war. Such a state of things naturally fostered a warlike spirit, and gave birth to military institutions; while the necessity of self-defence, still more than the love of conquest or of glory, rendered it imperative that every citizen capable of bearing arms should be ready to appear in the field at the call of his country. But experience soon taught the important lesson that numbers did not constitute strength, and that a small body of men prepared by early training for the duties of war, and subjected to a system of regular discipline, were capable of contending, on equal terms, with great numerical odds. When this discovery was first made, we have no means of ascertaining precisely; but it is one which must early have occurred to the rulers and governors of small states like those of Greece, the scanty population of which imposed upon them the necessity of devising the best means for rendering its disposable strength effective and available. Hence we find, that one great object of the early statesmen and legislators of this country was to organize a system of physical and moral education adapted to its peculiar position and circumstances; to engraft the military spirit on those institutions which were destined to form the general character of their countrymen; and, amidst the pursuits of peace, to prepare the minds and bodies of their citizens for encountering the fatigues, privations, and perils of war. Nor did their labours prove fruitless or vain; for the institutions thus prepared being suited alike to the genius and condition of the people, soon struck their roots, as it were, into the soil, and ere long produced those fruits which have for ages been the wonder and admiration of mankind. But less perhaps of this wonder and admiration is due to the bravery of the Greeks, eminent as it always was, than to their discipline, organization, and conduct in the field. Among them all the branches of the military art were simultaneously cultivated, and received the most important improvements. Their formation was rendered compact and formidable; combining solidity and the power of resistance, with a mobility which made these qualities available on different points, even in action. Their tactics were singularly adapted to the peculiar character of their troops, and were founded on the most certain principles of the art.[2] And, in later times, we find strategy recognised and taught as a science in the schools;[3] while, in the field, it received, in several respects, a development which no other nation, ancient or modern, has yet been able to surpass. Lastly, we may observe, that until the reign of Philip, the father of Alexander the Great, Greece had no standing army. Her strength consisted in her militia; and to this description of force she was indebted for the imperishable glories of Marathon, Platæa, and Mycale, when the myriads of the Persian invader were successively overthrown. But, from the causes above indicated, and the incessant contests in which the different states were engaged with each other, this militia had acquired the principal characteristics of a regular force, both as regards

---

[1] Guischardt, *Mémoires Militaires sur les Grecs et les Romains*, tom. i. p. 260–61.

[2] Guibert, in his *Discours Préliminaire*, part second, underrates the tactics of the Greeks. "Je compare les guerres des Grecs," says he, "et la plupart des guerres des anciens, à celles de nos colonies dans l'autre continent. J'y vois cinq ou six mille hommes les uns contre les autres, des champs de bataille étroits, où l'œil du général peut tout embrasser, tout diriger, tout reparer. *Un bon major conduiroit aujourd'hui la manœuvre de Leuctre et de Mantinée, comme Epaminondas*," p. 82. It will be fortunate for modern armies when their "good majors" are as skilful and as brave as Epaminondas.

[3] Guischardt *Mémoires Militaires*, tom. ii. p. 155.

organization and discipline, and consequently was of nearly equal avail against an enemy in the field.

The Spartan army.

To the institutions of Lycurgus Sparta was indebted for her military pre-eminence among the states of Greece. To exclude all refinement and luxury, to cultivate the sterner virtues of abstinence and self-denial, to inure the body to hardships and the mind to suffering, to inculcate self-sacrificing patriotism, and to form great characters, appear to have been the principal objects of this iron-hearted legislator; who accordingly laid the foundations of his institutions in a system of primary education, intended and calculated to convert the free male population of the state into a military community, and to develope to the utmost all those physical and moral qualities which render men invincible in war. Nor did the results disappoint the calculations upon which this system had been founded. Trained from their earliest years to suffer the extremes of heat and cold, hunger and thirst, to endure pain with unflinching fortitude, and to despise danger and death; habituated to the most implicit and unquestioning obedience to all placed in authority over them; and continually exercised in running, wrestling, swimming, ball-playing, and martial games of all sorts, as well as in stratagems, surprises, and ambuscades; the Spartan youth, when called to take the field, were prepared at once to enter upon the duties of war with alacrity and vigour, and to regard with indifference all the privations and fatigues of the severest campaign. Nor were their discipline and organization inferior to their military qualities. The Spartan phalanx, which formed the basis of the Macedonian, consisted of eight files in depth.[1] The files were placed at intervals of six feet from one another when disposed in open order; in close order the distance was three feet; in locked order one foot and a half; the intervals being thus diminished one-half at each approximation. The open order was that observed on the march, and in evolutions or manœuvres; the close order was for the attack; and the locked order was that in which an attack was received. The front rank consisted of picked men; the rear rank was also select; while those upon whom least dependence could be placed had their station in the centre, in order to give impetus and momentum to the column by their weight and physical power. The different parts of the phalanx were classed according to a regular system, and, in particular, the covering file was matched in quality as nearly as possible with the file in front; so that if the whole or any part of the front rank failed, the vacancies were supplied by the second files, without disordering the line. The arms, offensive and defensive, of the soldier, consisted of a spear or pike, a short sword or dagger, and a shield or buckler of an oval form, which was fastened round the neck and at the left shoulder by means of straps. But latterly Cleomenes changed this clumsy encumbrance for the Macedonian shield, originally invented by the Carians, which was fastened on the left arm by a ring or belt, so as to leave the soldier free to employ both hands in giving force and direction to the pike. The Spartans were also familiar with the most approved evolutions, which they performed with equal celerity and precision. The rear of the phalanx became the front, or the front the rear, by the shortest and simplest operation; while, by redoubling its formation, it became a solid square, bristling on every side with pikes, and, in locked order, wholly impenetrable to attack, except upon broken ground. Rapid changes of front even in the presence of an enemy, refusing or advancing a wing at a critical moment, turning an enemy's flank, and many other manœuvres, which are still considered equally delicate and difficult, were frequently executed with the most complete success by the commanders of these formidable columns. In a word, the Spartans may be regarded as the founders and first improvers of that military system, which attained its perfection under Alexander, and placed the crowns of Asia at his feet.[2]

The Athenian army.

The Athenian military force consisted of three classes; first, the heavy troops, ὁπλῖται, armed with a spear, a dagger, a cuirass or corslet, and an oval shield, and reserved for the phalanx or main battle; secondly, the light troops, πελτασταί, armed with a light spear, a javelin, and a target, and destined for skirmishing, seizing or maintaining positions, and covering the movements of the phalanx; thirdly, irregular troops, γυμνῆται, without defensive armour, but provided with missile weapons, such as javelins, bows and arrows, and slings, for harassing an enemy on his march, or performing the duties of light troops in the field.[3] The phalanx or main battle consisted entirely

[1] There is some confusion among the ancient writers on the subject of the division of the Spartan force. Thucydides, describing the arrangement and proportions of the Spartan army at Mantineia, informs us that a battalion or *lochos* consisted of four *pentecosties* or companies, a pentecostie of four *enomoties* or platoons, and each *enomotie* of 32 men; thus making the whole strength of the battalion 512 men. But he makes no mention of the number of battalions in a regiment, and indeed acknowledges that the subject was obscure, and his information imperfect. According to Xenophon, the Spartan *mora* or regiment consisted of four *lochi*, the lochos of two *pentecosties*, and the pentecostie of two *enomoties*. The number included in the last denomination is not given; but, if we assume that it consisted of 32 men, as stated by the historian first named, the regiment of Xenophon would amount to 572 men, or 50 more than the battalion of Thucydides. How are these discrepancies to be reconciled? It is scarcely probable that the division of the Spartan force underwent any change in the interval between the time of Thucydides and that of Xenophon; but it is very probable that neither may be correct, considering that the Spartans studiously concealed from the observation of foreigners the internal organization and strength of their armies.

[2] The Spartan phalanx advanced to meet the enemy's at a regular step, in accord with the cadence of military music, and, even when beaten, generally retired from the field in perfect order, however reduced in number. After battle, every soldier was obliged to produce his shield, as a proof that he had fought, or retired, as a soldier ought to do, bravely and steadily. If he had lost or thrown away his shield he was disgraced for ever; the brand of indelible infamy was fixed upon him. But this was of rare occurrence; for the love of military glory was the only passion which the Spartan people were allowed to cherish; and both education and discipline had combined to eradicate fear from their bosoms. It was a word unknown in their vocabulary. In this singular country all passions merged in one. The Spartan mother and the Spartan wife rejoiced when a son or a husband had fallen honourably in the field of battle, and sometimes refused to recognise as of kindred with themselves such of their relatives as had survived a defeat. The only mourners on account of the disaster at Leuctra were those whose friends and kinsmen had escaped the slaughter of that bloody day.

[3] These classes may be considered as analogous, the first to the grenadiers, the second to the light infantry, and the third to the riflemen or sharpshooters of modern armies. Their armour, however, was different at different times; for the Greeks, like the Romans, made several changes in this respect; and hence the apparent discrepancies which we meet with in the accounts of historians. For example, when Arrian mentions the militia of the ancient Greeks, he speaks of the times which preceded the constitution and organization which Philip and Alexander the Great gave to their troops. The oval buckler, larger than common, and the long pike or *sarissa*, were introduced by these sovereigns, and found to add incalculably both to the defensive and offensive power of the phalanx. Some of the Greeks, however, piqued themselves on not adopting the changes of Alexander; but Philopœmen at length persuaded the Achæans to lay aside their ancient arms, and assume those of the Macedonians.

of natives of Attica, and was drawn up according to tribes or communities, probably with the view of exciting a generous rivalry in deeds of arms. The light armed troops were partly native and partly foreign; the slingers and archers were wholly foreign. The cavalry, like the heavy-armed infantry, consisted of natives alone, and were of a good description, being remarkably alert, intelligent, and enterprising. Thus composed, the Athenian army was prepared for every species of warfare, and equal to the most arduous achievements. The intelligence, activity, quick perception, and daring spirit of enterprise for which the native of Attica, the Frenchman of Greece, was distinguished, rendered him formidable in desultory warfare, alert in his movements, and prompt in taking advantage of every favourable circumstance; insomuch that the Athenian light troops foiled, and on some occasions even discomfited, the renowned Spartan phalanx. The Athenian phalanx was less compact than that of Sparta, and, owing to the character of the people, as much perhaps as to its formation, less adapted to receive and repel an attack; but in the charge it was perfectly irresistible. Its onset was terrible, and overthrew all before it. The cause of this must be sought in the difference of national character. The Spartan was chiefly celebrated for his passive, the Athenian for his active courage. Hence the one was powerful in resistance; the other formidable in attack. The Spartan was steady, devoted, and firm; the Athenian bold, enterprising, intelligent, and full of address and dexterity. If the one was less capable of resistance, the other was more ardent and impetuous; their military qualities were as opposite as their natural characters, but both were admirable of their kind; and if it had been possible to combine them together in equal proportions, perfect soldiers might have been formed, and a perfect army organized. The Athenians, we may observe, were the first of the Greeks who advanced upon the enemy at an accelerated pace corresponding to what is now called double-quick time. This innovation was first introduced by Miltiades at Marathon, in order to give increased momentum to the charge which he directed against the Persian masses; and it was consecrated in Athenian tactics by the glorious result of that ever-memorable day.[1]

The Macedonian army.

But the very principles which had saved the states of Greece from foreign invasion, and enabled them to maintain their independence, were destined to form the basis of a military establishment, more formidable, because more complete in all its parts, than any which that or other countries had yet produced, and organized for the express purpose of serving as an instrument for subverting Grecian liberty. We allude of course to the Macedonian army in the reigns of Philip and his son Alexander the Great. The founder of this establishment, Philip of Macedon, was a man of unquestionable talents, of convenient principles, and of boundless ambition. Having improved his natural parts by associating with the scholars, statesmen, and philosophers of his age; and having been initiated into the scientific principles of the art of war under Epaminondas, the most celebrated master of the time; he was early fired with a love of military glory, and a lust of conquest and dominion. But although the brilliant period in the annals of the Greek states was past when Philip made his appearance, and these communities had already begun to show symptoms of decline, enough of the ancient spirit still remained to convince him, that, without creating new means, and organizing a force different from any which had yet existed, he could never hope to realise his ambitious projects, by rendering himself the master of Greece. The sagacity of Philip was fully on a level with his ambition. He saw that in the rude shepherds and hunters of Macedonia might be found the raw material of an army; that discipline and organization were alone wanting to convert this material into an invincible force; and that to render a military force completely effective, or, in other words, to derive from it the utmost benefit it was capable of affording, it was indispensably necessary to depart from the militia system which had hitherto prevailed, and to start from the principle that no army could be good which was not permanent. He was thus the first who fully comprehended the importance of a standing army, both as regards the efficiency of a military body itself, and also with reference to projects of conquest or ambition; and he may further claim the distinction of having been the first to organize a permanent force. In prosecuting this design he showed a skill, and a knowledge of the principles of military organization, equal to the sagacity evinced by its conception. Adopting the Spartan phalanx as the basis of his system, he gave it greater depth and solidity, so as to render it irresistible in the attack, and impenetrable when drawn up in position. He changed or improved its armour both for offence and defence; and, in particular, introduced the large oblong buckler, and the *sarissa* or Macedonian pike, the most formidable weapon of ancient times. The light-armed troops were also placed on a better footing than they had ever before been among the Greeks, being formed in demi-phalanges, which, without materially lessening their mobility, rendered them capable of combining their efforts in an effective manner with those of the heavy-armed infantry. The equipments, arms, and discipline of his cavalry were in like manner improved, and their organization perfected, with the utmost care and diligence. In a word, all that was excellent in the different Greek systems was combined in the Macedonian; while their defects were avoided, and improvements introduced wherever these seemed to be either expedient or necessary. Such was the general character of the military establishment which Philip created for enabling him to trample on the liberties of Greece, and which Alexander employed in subjugating the world. We shall now speak of its different parts in detail.

The phalanx was composed of files of a certain depth, and of regular combinations of those files. The *lochos* or file was a number of soldiers ranged in line, one behind the other, from the head to the *serre-file* or *ouragos*. The file consisted at different times of different numbers of men, as eight, ten, twelve, and sixteen. Alexander chose the last, because it formed the best proportion relative to the extent and depth of the phalanx; nor did it prevent the archers and slingers, stationed behind, from launching their missiles at the enemy, over the heads of the phalangites. If the phalanx was doubled to form a solid column, or reduced to one half in order to extend its front, the respective depths of 32 and 8 still remained proportional; but if the original depth of the file had been only 8, as in the Spartan phalanx, the latter evolu-

[1] It is very much to be regretted that no military or scientific description has been preserved of the battle of Marathon. The accounts which have reached us, being written by men ignorant of military affairs, are meagre, confused, and unsatisfactory; containing details, indeed, of the numbers engaged, and the amount of the slain, but giving little or no information respecting the combinations and manœuvres which decided the fortune of the day. One thing only is certain,—the victory was the result of consummate generalship on the part of the commander, and of heroic valour on that of the soldier.

tion could not have been performed with safety, because it would have reduced the depth to 4, and thus deprived the formation of its peculiar characteristic of solidity. The preference given to the number 16, therefore, was on account of its divisibility, and its admitting of evolutions consistently with the nature of the phalanx, which could not have been attempted with files composed of any other number, greater or less. The best man was chosen as the head of the file, and named *lochagos* or *protostate;* the second was called *epistate;* the third bore the same name as the first, the fourth the same as the second, and so on to the last; so that each file was composed of *protostates* and *epistates*, ranged alternately from the *lochagos* to the *ouragos*, who was also a picked man.[1] The junction of two or more files was denominated *syllochism*. It was effected by placing the *protostates* and *epistates* of the one exactly opposite the *protostates* and *epistates* of the other; and one man, considered in reference to his juxtaposition with another, was called *parastate*. The junction of all the files formed the phalanx; of which, therefore, the *lochagi*, or heads of files, constituted the front rank, and the remaining *parastates* in alignement, as far as the *ouragi* or *serre-files*, the depth.

The phalanx, thus composed, was divided into two equal parts; one called the right wing or head, and the other the left wing or rear. The point of separation or division was variously denominated the navel, the mouth, and the jointure of the phalanx. And as the principle of this formation was, that every combination should be divisible into two equal parts, so the phalanx, as finally constituted by Alexander, was composed of 16,384 heavy-armed men, the half of which number was considered sufficient for light troops, and the half of that again, or the fourth of 16,384, sufficient for cavalry; while the divisibility into equal parts afforded great facility for executing with precision all manner of evolutions, and extending or diminishing at pleasure the front of an army. The total number of the phalanx being, as already stated, 16,384, and each file consisting of 16 men, it follows that there were in all 1024 files. But each combination of files had its peculiar and appropriate denomination. Two files united formed a *dilochie*, under a *dilochite;* four files, a *tetrarchie*, under a *tetrarch;* two tetrarchies, a *taxiarchie*, under a *taxiarch* or *centurion;* two taxiarchies, a *syntagma* or *xenagie*, under a *syntagmatarch* or *xenagos;*[2] two syntagmata, a *pentecosiarchie*, under a *pentecosiarch;*[3] two pentecosiarchies, a *chiliarchie;* two chiliarchies, a *merarchie* or *telarchie;* and two merarchies, a *phalanx* of 4096 men in 256 files, which was commanded by a general, under the name of *phalangarch*. Again, two phalanges formed a *diphalangarchie;* and two diphalangarchies, a *tetraphalangarchie*, or the grand phalanx, which thus consisted of two wings or diphalangarchies, four phalanges, eight merarchies, 16 chiliarchies, 32 pentecosiarchies, 64 syntagmata, 128 taxiarchies, 256 tetrarchies, 512 dilochies, 1024 files, and 16,384 men. The front might be extended by simply augmenting the distance between the files; the phalanx was closed by lessening the distances between the ranks and the files, and thus diminishing both its front and its depth. Its locked order was called *synapism*, in which the ranks and files were so closely approximated, that the soldier could not turn.[4] In this formation the men at the exterior of the mass held their bucklers before them; the next rank raised their bucklers over the heads of those immediately in front of them; the third rank held their bucklers over the heads of the second, and so on; thus forming a sort of roof, over which the archers in the rear sometimes passed to the front, and which, from the bucklers being joined like the scales of a crocodile, resisted and threw off the heaviest missiles discharged by the enemy. As every thing depended on the steadiness of the heads of files and their *epistates* of the second rank, both were *gens d'élite* or picked men. When the phalanx was closed for action, each man occupied only three feet of ground in rank and file. The pikes or *sarissæ* were 24 feet in length, 6 feet being behind and 18 feet before the grasp; consequently (as the ranks were three feet separate), the second rank advanced the pike 15 feet, the third 12, the fourth 9, the fifth 6, and the sixth 3 feet; thus presenting an array of points such as never bristled along the front of any other military mass or column. The soldiers of the other ranks, as they could not employ their pikes, pushed on those before them, and, by their weight, served to augment the violence of the shock.[5] In this case every thing depended on the *serre-files* or *ouragi*, who were the keys of the phalanx, and, like the *lochagi*, picked men. Such was the Macedonian phalanx,[6] which was destined to conquer the world, and to be, in its turn, conquered by the world's conquerors. It yielded to superior tactics and greater mobility.

The light-armed infantry were drawn up in different ways, according to the nature of the ground and the dis-

[1] Some authors designate a file *stichos*, others *decuria*. They who apply the latter epithet seem to suppose that it consisted of ten men, which is not true as respects the Macedonian file. We have followed, in the text, the nomenclature of Arrian, whose authority on this subject is decisive. With regard to the term *enomotie*, which has so much puzzled commentators, we have already shown that it means something different from a file, or part of a file. It was a term peculiar to the military system of Sparta, whence it passed into the other systems of Greece, including the Macedonian; but no data have been given from which its precise import can be ascertained.

[2] The *syntagma* or *xenagie* had four supernumerary men; a standard-bearer, an officer who marched behind and performed the duty of our major, an adjutant, and a crier to repeat the orders. This section, ranged in order of battle, formed a perfect square. (Arrian's *Tactics*.)

[3] The *pentecosiarchie* of the Macedonians answered to the *lochos* of the Spartans. This must be kept in mind in the perusal of Thucydides and Xenophon, otherwise both will be unintelligible.

[4] It was to this locked order that Epaminondas was indebted for the victories which he gained over the Lacedæmonians at Leuctra and at Mantineia. The Theban army was formed in columns of attack, upon a front considerably less than the depth. The shock, therefore, proved too much for the Spartan phalanx, which was only eight deep. Xenophon compares it to that of a heavy vessel striking a light one amidships with her bow, and dashing her to pieces by the collision.

[5] The loss of men in the day of battle, or the necessity of sending out detachments, made no change in the form and disposition of the phalanx. The sections were always kept up to their full complement of ranks and files. The effective diminution fell, not upon the ranks and files, but upon the number of the sections, which were retrenched in proportion as they filled up the void in the phalanx.

[6] The Macedonian phalanx, says Arrian, was as formidable in appearance as it was in reality; and Paulus Æmilius confesses, that, when he saw, for the first time, this imposing mass, with its front bristling with the terrible *sarissæ*, he was struck with consternation. Guischardt alleges that it was "plus terrible à l'aspect que dans l'effet;" and adds that Paulus "ne laissa pas que de la battre avec ses Romains épars et distribués en plusieurs pelotons." But if Alexander had commanded it, the Roman would have told a different tale. Guischardt has himself demonstrated that the loss of the battle of Cynocephale was mainly, if not exclusively, owing to the stupidity of Philip in committing the phalanx upon broken ground, where its flanks were uncovered, and the principal advantages of its formation lost.

position of the enemy; sometimes before the phalanx, sometimes behind it, sometimes on both wings, sometimes only on one. Their formation was in all respects similar to that of the phalanx, and their files, eight deep, were combined upon analogous principles. The Macedonian cavalry was of various descriptions, as *kataphracti*, light horse, and *acrobolistæ*. The *kataphracti* or cuirassiers were completely covered with defensive armour; the man with a cuirass and cuisses of iron scales, the horse with a frontlet and mail. Their offensive arm was the Macedonian pike. The light cavalry, unencumbered with heavy armour, carried lances and missile weapons. The *acrobolistæ* had no lances, and, like the Armenian or Turkish cavalry, used only the bow and arrow. They were a species of Cossacks or irregular horse, and performed the duties of such. The usual formation of the regular cavalry for attack was the cuneiform, which had been introduced by Philip, from an idea that it was the order best calculated to pierce an enemy's line; but they were sometimes drawn up in squares, sometimes in the form of a rhombus, and sometimes also in a line.

The numerical strength of the Macedonian, like that of other ancient armies, can only be conjectured from the numbers actually brought into the field. In the time of Philip it probably never exceeded a grand phalanx, with its proportional complements of light troops and cavalry, 28,603 in all, and a few thousands of auxiliary troops. At the passage of the Granicus, Alexander's army consisted of above 30,000 infantry and 5000 cavalry; from which we may conclude that it was composed of one grand phalanx, with its proportional complements of light troops and cavalry, and about 6000 auxiliaries. But it was afterwards powerfully reinforced; for Alexander paid great attention to recruiting, especially in Greece, and had always generals detached from the army for the purpose of raising new levies in that country. Accordingly we find that, at the battle of Arbela, the Macedonian army consisted of two grand phalanges, or 32,768 heavy armed infantry, two corps of *peltastæ*,[1] each 8186 strong, and 4096 cavalry, including the Thessalian horse, besides several thousand auxiliaries, chiefly irregular troops; thus making a grand total, including auxiliaries, of at least 60,000 fighting men, or 54,000 regular and 6000 irregular troops.

It has been supposed by some that this army, like that of Carthage, was heterogeneous in its composition; that men of all nations were to be found in its ranks; and that a stern, unrelaxing discipline constituted the only *vinculum* or tie by which the naturally discordant mass was held together. There cannot possibly be a greater mistake. The Macedonians, it is true, formed but the nucleus, as it were, of the army; and, both in the reigns of Philip and Alexander, recruits were obtained in considerable numbers from the neighbouring states of Greece. But whatever shades of difference might have been produced by local circumstances and diversity of institutions, the inhabitants of all these states were essentially one and the same people; identical in origin, distinguished by like peculiarities physical and moral, and possessing a general national character. In what respects, then, can the Macedonian army be considered heterogeneous? None but Greeks were admitted into the ranks of the phalanx, or those of the light infantry and cavalry; no barbarians were received even as auxiliaries. It was composed exclusively of people of the same country and the same general character, who all spoke dialects of the same language, shared a common temperament, and were distinguished by their physical configuration, no less than by their intellectual and moral attributes, from the inhabitants of the surrounding nations. If ever there was an army, therefore, which discipline could render more completely homogeneous than another, it was that of Macedon during the reigns of Philip and Alexander; nor do we know of any modern army to which this epithet can with equal justice be applied. The British army is composed of English, Scotch, Irish, Welch, and Highlanders; the French, of Bretons, Normans, Gascons, Alsatians, Savoyards, and many other tribes; the Austrian, of Hungarians, Bohemians, Transylvanians, Croatians, and Germans; the Prussian, of Silesians, Saxons, Poles, Pomeranians, and Brandenburgians; and the Russian, of Muscovites, Poles, Sclavonians, Tartars, Circassians, Armenians, and innumerable other races; yet all these are considered national armies, and have each, in fact, a national character. But if such assemblages are to be regarded as homogeneous, we know not upon what principle the Macedonian army, composed exclusively of Greeks, can possibly be viewed in a different light, or supposed to have had no other bond of union than what was created by discipline alone.

The Theban and Achæan armies.

The only other Greek armies which seem to require notice are those of the Thebans and of the Achæan League. The Theban army, like Theban independence, may be said to have been created by Epaminondas, and to have expired when that great captain fell in the arms of victory upon the field of Mantineia. Still it is a striking example of what genius and discipline may effect, even when called to work upon the most unpromising materials. Epaminondas found it a rabble, and he left it the most formidable military force which Greece had ever yet known. He gave it that organization which rendered it victorious at Leuctra and Mantineia, and which shook to the very foundation the power of the Lacedæmonians. Aware that the Spartan phalanx was invincible by any similar formation, and that he could only hope to prevail by bringing against it a greater concentration of physical energy, he organized the Theban army in columns upon a front less than their depth, so as to enable him to direct the whole or any part against a given point of the enemy's line, and to bear it down by an irresistible superiority of force; and he adapted his tactics to this organization. At the battle of Leuctra, accordingly, Epaminondas, observing the Lacedæmonians advance their two wings before the centre, so as to form the order which the Greeks called the half-moon, instantly attacked the centre of one of these wings, and, having penetrated it, soon succeeded in throwing the whole into irretrievable confusion. Here the onset was made by one wing in column against another in comparatively open formation; and hence the Theban order of attack became the oblique, which is erroneously supposed to be a discovery of modern times. At Mantineia the Lacedæmonians carefully avoided the blunder for which they had paid so dear at Leuctra, and kept their forces more concentrated; but Epaminondas, forming the whole of his infantry in a single column, precipitated it upon a part of the enemy's line, overthrew it, and thus decided the fortune of the day. The Theban army, immediately after the battle of Leuctra, is said to have amounted to 50,000 men. This, however, is probably an exaggeration.—With regard to the army of the Achæan League, it continued insignificant for

[1] For an able and learned account of the *peltastæ*, who sometimes formed considerable bodies, particularly in the armies of Alexander and his successors, and whose reputation almost equalled that of the phalanx itself, see Guischardt's note to his Translation of Arrian's *Tactics*, in the second volume of his *Mémoires Militaires*, p. 177.

the greater part of a century after that celebrated confederacy was entered into. Aratus was the first who placed it on a respectable footing, and taught it to conquer at Caphyæ; and he was succeeded by Philopœmen, incomparably the most scientific commander of ancient times, who completed its organization, and led it to victory at the second battle of Mantineia, where the Spartans, under Machanidas, were completely defeated, and the tyrant himself slain by the hand of the Achæan chief. This victory was exclusively owing to the superior tactics and dispositions of Philopœmen; who, instructed by the successes of the Romans, had contrived, with infinite skill, to combine, in the formation and arrangement of his troops, the advantages of the legionary order with those of the phalanx. The invaluable fragment of Polybius, containing a description of the battle of Mantineia, gives no account of the numbers engaged. We learn, however, that Philopœmen having assembled the troops of the League, spent eight months in perfecting their discipline and organization before he ventured to commit them in the field against so experienced and warlike an enemy as the Spartans.[1] An army is a piece of mechanism which only acts effectively when all the parts are combined and adjusted together so as to insure the most complete concert and unity of operation; and discipline is the mean by which this important result is produced. It is in fact the art of creating a new power; and so great is its efficacy that it sometimes developes in men those qualities which it only professes to direct and regulate.

The Carthaginian army.

This remark is strikingly exemplified in the history of the Carthaginian army. That army was almost entirely composed of mercenaries, or at least of levies drawn from countries differing in language, in manners, in customs, and in character. In its ranks were to be found Africans, Spaniards, Gauls, Boians, Insubrians, Etruscans, and various other races; yet such are the fusing effects of discipline, that this apparently heterogeneous mass vanquished the Romans on the Ticino; overthrew their legions in three pitched battles, at Trebia, Thrasymenus, and Cannæ; and, if Hannibal had known how to profit by victory, might have planted the Carthaginian standards amidst the ruins of Rome. The advantages of a truly national army are great, especially in reverses: it may be beaten, but cannot easily be destroyed: and even its disasters may teach it that experience which will ultimately conduct it to victory; as happened to the Romans in ancient, and to the Russians under Peter the Great, in modern times. But, on the other hand, many instances might be produced to show, that the most effective armies may be organized out of the most discordant and unpromising materials; and that, while nothing can supply the want of discipline, discipline can almost atone for and remedy every thing. With an army composed as we have already described, Hannibal maintained, during sixteen years, the war against the Romans in Italy, without sustaining any serious reverse; nor did he withdraw, until his presence was rendered necessary for the defence of his country; which the successive defeats of the other Carthaginian commanders, both by sea and land, had uncovered, and exposed in its turn to the attacks of an invader. Finally, he was vanquished at Zama from the same cause which had rendered him so often victorious—namely, superiority of discipline: for although his military genius never shone forth more transcendently than in his last field, and although his dispositions were in all respects worthy of his high reputation, yet the raw and undisciplined levies which formed the strength, or rather the weakness, of his army, were in no condition to contend with the Roman legions, whom sixteen years of incessant warfare had improved both in discipline and experience.[2] In reflecting upon the issue of this decisive conflict, which terminated the long and sanguinary struggle between the rival republics of Carthage and Rome; and, above all, in considering the precarious nature of that power which is built on the uncertain foundation of military glory; the mind insensibly passes from the contemplation of the fate of the Carthaginian chief to that of a still greater commander, which in some measure resembles it—from the days when these warlike republics contended for the empire of the world, to our own times, when, in a new field of Zama, another Scipio conquered another Hannibal.

With regard to the numerical strength of the Carthaginian army, it appears to have varied at different times. The force with which Xantippus defeated Regulus, and made him prisoner, did not probably exceed 20,000 men; and we learn incidentally that the heavy-armed infantry which the Lacedæmonian had formed in phalanx, conformably to the tactics of his country, amounted to between 8000 and 9000 men, and were all native troops. But when the Carthaginians afterwards invaded Spain, they recruited their armies from the population of the country, and that of the neighbouring provinces of Gaul, until the total numerical strength of these must have considerably exceeded 100,000 men. Livy assures us that Hannibal set out on his expedition to Italy at the head of 100,000 foot and 10,000 horse, but that he lost 30,000 men in crossing the Alps; so that, according to the Roman historian, he must have entered Italy with about 80,000 men. But the numbers actually brought into the field completely disprove this statement: for it is admitted by Livy himself that, at Trebia, Hannibal had only 30,000 infantry and 10,000 cavalry, and that he vanquished at Cannæ with 40,000 foot and 10,000 horse. We shall be nearer the truth, therefore, if we suppose that the invasion of Italy was undertaken with little more than half the number of troops mentioned by Livy; and that the losses sustained in crossing the Alps were, in a great measure, repaired by the recruits which Hannibal drew from the Boians, Insubrians, and his other allies; a supposition which seems completely borne out by the authority of Polybius. But when the Carthaginian general set out from New Carthage for Italy he left two other armies in Spain; and, if we assume these to have been each about 30,000 strong, while the force under his own command exceeded 50,000, it will follow that, at this time, the Carthaginians had considerably more than 100,000 men of all arms in the field.—Let us now attend to the composition and organization of that strictly national force with which these well-disciplined condottieri were called to contend, and by which, after sustaining many reverses, they were ultimately overthrown.

The Roman army.

The army of Rome, in the days of her conquests, was perhaps the most perfect, certainly the most formidable, which the world had yet seen; and the superiority which it ultimately obtained over the military force of every nation to which it was opposed, seems to have been exclusively owing to the pre-eminent excellence of its discipline and organization. "Nulla enim alia re videmus populum Romanum orbem subegisse terrarum," says Vegetius, "nisi armorum exercitio, disciplina castrorum, usuque militiæ. Quid enim adversus Gallorum multitudinem paucitas Ro-

[1] See Guischardt's commentary on this battle, *Mémoires Militaires*, tom. i. p. 177.

[2] We must again refer to Guischardt, tom. i. p. 216, more especially as this very able military commentator exposes the misrepresentations of Folard, who seems to have been alike incapable of comprehending the narrative of Polybius, or the dispositions of Hannibal.

mana valuisset? Quid adversus Germanorum proceritatem brevitas potuisset audere? Hispanos quidem non tantum numero, sed etiam viribus corporum nostris præstitisse, manifestum est. Afrorum dolis atque divitiis semper impares fuimus. Græcorum artibus prudentiaque nos vinci, nemo unquam dubitavit. Sed adversus omnia profuit tyronem solertem eligere, jus (ut ita dixerim) armorum docere, quotidiano exercitio roborare, quæcunque evenire in acie, atque in prœliis possint, omnia in campestri meditatione prænoscere, severe in desides vindicare. Scientia enim rei bellicæ, dimicandi nutrit audaciam. Nemo facere metuit, quod se bene didicisse confidit. Etenim in certamine bellorum, exercitata paucitas ad victoriam promptior est: rudis et indocta multitudo, exposita semper ad cædem."[1] The military age was seventeen; and, when the exigencies of the state required it, every citizen, from seventeen to forty-six, or even fifty, was obliged to enrol himself as a soldier. Except on pressing emergencies, however, the more youthful part of the population was preferred, as that which could be most effectually trained to the exercises and formed to the discipline of war.[2] These were of the most severe description, and had for their object not merely to instruct the soldier in the use of arms, in marching, and in evolutions, but to develope and improve to the utmost his physical powers; to inure him to labour, fatigue, and hardships of all kinds; to qualify him for surmounting with ease the various obstacles and difficulties incident to a state of active warfare; to give precision and rapidity to his movements; and, above all, to create that confidence in himself, and that unbounded reliance upon the efficacy of order, subordination, and combined action, which nourish audacity, yet temper it with coolness and steadiness. Besides the use of arms, of which we shall hereafter speak, the young soldier was, accordingly, trained to the exercises of running, leaping, vaulting, wrestling, and swimming, armed as well as unarmed: he was required to perform long and frequent marches, at the rate of four miles an hour, carrying a load of sixty pounds weight: he was carefully instructed in the use of the tools necessary for throwing up all manner of field-works, particularly fortifying the camp: and, even after he had been found qualified to join the legion, he was constantly employed, while in camp, either in the practice of these manly exercises, or in acquiring greater dexterity and precision in the use of his weapons. The Roman soldier knew no intervals of idleness, and was not allowed time to indulge in dissipation. The camp was his home: war was his business: its exercises formed his amusement: its success constituted his glory. In the legion to which he belonged were concentred all his hopes, all his thoughts, and all his affections.

In raising troops to constitute the legions, the method adopted by the Romans was that which they denominated *election;* because the magistrates chose from the different tribes the citizens whom they considered best fitted for the military service. The consul or the prætor assembled in the Campus Martius, or in the Capitol, all the citizens, who were bound to concur in the formation of the legions, raised every year, conformably to a decree of the senate; and this obligation included all Romans within the age above specified, who had not served twenty campaigns as foot soldiers, or ten campaigns as horsemen or knights; with the exception, however, of the lowest class, which was exempted from military service on account of its poverty. The number of legions commonly raised was four;[3] and the first step consisted in the appointment, either by the people or the consuls, of six tribunes to each legion. The conscripts being classed according to their tribes, the magistrate, charged with the levies, then elected four successively from each tribe. Of every four thus designed the tribunes of each legion in their turn chose one, whose name was immediately inscribed in its muster roll; and this operation, which established a perfect equality in the composition of the legions, was repeated until they had received their proper complement of men. On the termination of the election each legionary individually took the *sacramentum* or military oath; swearing to be obedient to his general, and to execute his commands in all things to the utmost of his power and ability. Nor was this a vain ceremony; for the Romans, trained up in the fear of the gods, had a peculiar reverence for the sanctity of an oath. Roman citizens alone were admitted into the legions, until the time when the civil wars led to the subversion of the republic, and the violation of all established rules. Those, however, who had completed the prescribed period of service, or had attained their fiftieth year, were no longer obliged to take arms in defence of the state, and were only liable to be called out in the event of the city being threatened with some imminent danger. But these brave veterans, habituated to a military life, frequently inscribed themselves as volunteers, and thus served both as models and examples to the young legionaries, who seldom failed to profit by their experience, and generally showed an ambition to come up to their standard.

As soon as the military oath had been administered, the tribunes dismissed the legionaries, having first indicated the time and place where they were afterwards to assemble in order to be embodied. At the general muster, on the day fixed for this purpose, the youngest and poorest in each legion were selected as *velites;* the next in order were chosen as *hastati;* the class immediately above constituted the *principes;* and the *triarii* were formed of the oldest and richest citizens elected to serve in the legions; the different classes being thus arranged according to their arms, their fortune, and their age. The legion was commonly composed of 1200 *hastati*, 1200 *principes*, 1200 *velites*, 600 *triarii*, and 300 cavalry or knights; thus making its total

[1] Vegetius, *De Re Militari*, l. i. c. 1. Raphengii, 1607.

[2] "Adolescentes legendi sunt, sicut ait Sallustius: nam primum juventus, simul ac belli patiens erat, in castris per laboris usum militiam discebat. Melius enim est, ut exercitatus juvenis causetur ætatem nondum advenisse pugnandi, quam doleat præteriisse. (Vegetius, l. i. c. 4.)

[3] A consular army consisted of two legions, and of a certain number of troops furnished by the *socii* or allies of Rome. The infantry of the allies, according to Polybius, did not surpass in number the legionary infantry in a consular army, but their cavalry was double the number of the knights. The fifth part of their infantry and the third part of their cavalry formed a *corps d'élite*, called *extraordinary* or *elect*, under the immediate orders of the consul; while the remainder of the social troops were divided into two corps, one called the right and the other the left wing. Hence a consular army consisted, in Roman troops, of 6000 legionaries of the line, 2400 *velites*, and 600 knights; in social troops, of 6700 infantry of the wings, 1700 extraordinary infantry, 800 cavalry of the wings, and 400 extraordinary cavalry; making a total of 18,600 men. But when Rome had a difficult war to carry on, two consular armies were raised, and both the consuls took the field; which, in fact, happened almost every year. Lastly, when urgent circumstances required it, the consular armies were doubled and united in order to contend with a formidable enemy. Thus the Romans assembled at Cannæ four consular armies, or nearly 80,000 men, to try the fortune of arms against Hannibal; and, in the heat of the second Punic war, they raised as many as twenty-three legions, or considerably more than 100,000 men. "Alors," says Rogniat, "les armées se multiplièrent en raison de ce grand nombre de légions; les deux consuls choisissaient celles qui leur convenaient, et le commandement des autres était confié à des préteurs, à des proconsuls, et à des propréteurs." (*Considérations sur l'Art de la Guerre*, p. 29, 30.)

strength 4500 men. The tribunes, in concert with the centurions, divided the three classes of *hastati*, *principes*, *triarii*, into ten *ranks*, *manipules*, or *companies* each: the *velites* were distributed in equal portions among these thirty manipules: and the cavalry were divided into ten parts, called *turmæ* or troops. Such is the account given by Polybius, who, doubtless, describes the legion as it was constituted in his time.

The *hastati*, so called from the *hasta* or spear with which they were originally armed, commonly formed the first line in the order of battle; the *principes* were placed in the second line; whilst the oldest and best legionaries, classed under the name of *triarii*, constituted a reserve in the third line. The *triarii* were originally the only troops armed with the *pilum*, a species of heavy javelin, which will be described hereafter; and hence they are sometimes designated by the ancient historians under the name of *pilani*, while the *principes* and *hastati* are denominated *antepilani:* but these denominations necessarily ceased when the three lines adopted the same arms. The *velites*, distributed among the manipules, as already mentioned, were the light infantry of the legion, of which they formed about a fourth part; and known at first under the name of *rorarii* and *accensi*, they were afterwards called *velites*, and ultimately *ferentarii*. But the reader must be careful not to confound these light troops, which always formed part of the legion, with the cohorts of archers and slingers attached to the armies in the time of Cæsar; since the latter were merely auxiliary troops, and had nothing whatsoever in common with the legion. The legionary cavalry, composed of a body of 300 horse, denominated the *ala* or wing, and forming about the twentieth part of the legion, was divided into ten *turmæ*, of thirty horsemen each; while the *turma* was again subdivided into three *decuriæ*, of ten cavaliers each; and the whole was chosen from among the *equites* or knights, who formed one of the first orders at Rome.

When the classification had been completed, the tribunes of each legion proceeded to the appointment of centurions. They commenced by naming ten *first centurions* in each class, except that of the *velites;* after which they proceeded to the nomination of an equal number of *second centurions;* and the legionary infantry being divided into ten manipules of *hastati*, ten of *principes*, and ten of *triarii*, among which the *velites* were equally distributed, they assigned a first and a second centurion to each manipule; the first commanding the right, and the second the left of the manipule, under the orders of the first, whose place he supplied in the case of absence or death. The tribunes also named three decurions in each of the ten *turmæ* of horse; but the decurion first named had the sole command, and the two others were only his lieutenants. Thus a legion had sixty centurions or officers of infantry, thirty decurions or officers of cavalry, and six tribunes or officers of the staff. The tribunes commanded the legion each in his turn during two months; and this continued to be the practice until the epoch of the civil wars, when, for reasons sufficiently obvious, the command was intrusted to a *legatus* or lieutenant-general. The tribunes on service superintended the establishment and fortification of the camp, disposed the guards necessary for insuring its safety, transmitted to the centurions the orders of the general, took care that these were duly executed, and attended to the discipline and exercise of the troops; whilst the others were placed by the *legatus* or the consul at the head of detachments, reconnoissances, or foraging parties, and intrusted with the command of posts, or employed on particular missions, for raising contributions of money, provisions, clothing, and arms in the conquered countries; in a word, they were staff officers disposable for all kinds of service. The centurions were divided into several grades. Besides the distinction of first and second, established with reference to the manipule, they took precedence among themselves according to the relative distribution of the classes to which they belonged; so that a centurion of the *triarii* ranked above a centurion of the *principes*, and a centurion of the *principes* above a centurion of the *hastati*. And the first centurion of each class, that is, the *primi hastati centurio*, the *primus princeps*, and the *primipilus* or *primipili centurio*, commanded the whole of his class, or one of the lines of battle of the legion; which accounts for the high consideration that these three superior officers enjoyed among the Romans. They were commonly admitted to the council of the general, along with the tribunes; and the *primipilus*, the chief of all the centurions, by reason of the pre-eminence of his class, commanded the whole legion in the absence of the tribunes. Further, each centurion and decurion chose for himself, or received from the tribunes, a sub-officer to aid him in the details of the service; and we learn from Vegetius, that there was moreover placed at the head of each squad or tent of ten soldiers a *decanus* or corporal, who performed the duties of that humble rank.[1]

Such was the constitution of the legion in the time of Polybius, the friend and contemporary of the second Scipio. But an important, we might almost say a radical, change in its organization was afterwards introduced; a change which has been ascribed to Marius, and which appears to have commenced at the epoch of the wars against Jugurtha. The legions then ceased to be ranged in lines of *hastati*, *principes*, and *triarii;* for the last order of battle, according to the ancient formation, of which historians give any account, is that of Metellus against Jugurtha, as described by Sallust. From this period we always find the legions ranged by cohorts, without distinction of classes, in a double or a triple line. The classification which had been originally occasioned by difference of arms no longer served any purpose, after all the troops of the line were armed in the same manner; except to divide the legion into three large bodies of about 1600 each, including the *velites*, which formed part of them But experience proving that such bodies were too numerous to be easily directed by a single commander, and too heavy and lumbering for the exigencies of Roman tactics, their place was supplied by a number of smaller and more manageable bodies, and the legion, consequently, divided into ten cohorts, each consisting of three manipules, under six officers, who preserved their denomination and command in their respective manipules. The force of the cohort was raised from 400 to 600 men, thus making the total strength of the legionary infantry 6000; and the first cohort was composed of picked men, who were intrusted with the eagle, under the orders of the *primipilus*. A new order of battle was also adopted, the legions being commonly drawn up in two lines of five cohorts each, leaving small intervals between each cohort. But Cæsar, justly considering these *lacunæ* dangerous, and thinking the new formation deficient in solidity, preferred a continuous alignement, and recurred to the ancient formation in three lines, placing four cohorts of each legion in the first, three in the second, and three in the third line.

[1] Erant decani, decem militibus præpositi, qui nunc caput contubernii vocantur. (Vegetius, *De Re Militari*, l. ii. c. 8. See also Rogniat, *Considérations sur l'Art de la Guerre*, p. 7, et seqq. Paris, 1820.)

The civil troubles which led to the subversion of the republic produced still further changes. For a time the legionary cavalry entirely disappeared, and their place was supplied by auxiliary horse: strangers, and even slaves, were admitted into the legions, the force of which varied from 4000 to 6000 men: and the social troops disappeared by the admission of all the natives of Italy to the rank of citizens. In the imperial times, as we learn from Vegetius, the legion consisted of 6100 infantry and 726 cavalry. The decimal division of the infantry into cohorts remained the same. "The cavalry," says Gibbon, speaking of that attached to an imperial legion, "without which the force of the legion would have remained imperfect, was divided into ten troops or squadrons; the first, as the companion of the first cohort, consisted of 132 men, whilst each of the other nine amounted only to 66: the entire establishment formed a regiment, if we may use the modern expression, of 726 horse, naturally connected with its respective legion, but occasionally separated to act in the line, and to compose a part of the wings of an army."[1] This is at once clear and precise. But it has, nevertheless, been supposed, and not without reason, that when the legionary cavalry was augmented, the number of *turmæ* was proportionally increased; and that no such inequality as that mentioned by Gibbon existed between the *turma* attending the first cohort and those attached to the others. In fact the *turma* or squadron, at this period, consisted of 32, or, including the decurion, 33 men; and as the total number of cavalry belonging to the imperial legion was 726, it follows that there were in all twenty-two *turmæ*, of which four, or 132 men, were attached to the first cohort, and two, or 66 men, to each of the remaining nine. The result in both cases, however, is the same; while Gibbon's statement may perhaps be preferred as proceeding upon the more ancient division.[2]

The armour of the Roman infantry consisted of the demi-cylindrical buckler or shield, the cuirass or pectoral, the casque or helmet, and the ocrea or greave. The demi-cylindrical buckler or shield, four feet in length by two feet and a half in breadth, and constructed in the form of a tile, was composed of two or three pieces of timber fashioned and secured together in the manner of staves, covered with leather, strengthened at each extremity by a band of iron, and provided in the middle with an *umbo* or boss of metal, for the purpose of turning aside the missiles and pikes of the enemy. The casque, helmet, or head-piece of brass was variously formed, but generally fitted with projections at the base for protecting the neck and shoulders, and attached under the chin by *mentonnières*, covered with scales of brass. The cuirass or pectoral was a hollow plate of brass about a foot square, adapted to the form of the chest, and fastened with thongs of leather protected by metallic scales; but the centurions and foremost legionaries rendered themselves still more impenetrable to the steel of the enemy by using chain armour covered with brass scales. Lastly, the ocrea was a species of boot or greave, fortified with iron, and worn on the right leg, which the soldier advanced in striking his adversary.[3] Their offensive arms were the javelin, the *pilum* or heavy dart, the pike, and the sword. The sword called Spanish[4] was common to all the infantry of the legion. It had a short broad blade of excellent temper, which served either to cut or thrust,[5] and was worn by the soldier on the right thigh. The javelin belonged exclusively to the light infantry or *velites*. It was a species of dart, with a round shaft about three feet in length and an inch in diameter, shod at one extremity with iron about four inches in length, and tapering to a very sharp point. In the day of battle the light troops had each seven of these weapons, which they launched at the enemy with much dexterity and precision. When it became necessary to have recourse to the sword before the whole or any part of the javelins were thrown, the soldier passed them to his left hand, which remained free in consequence of the buckler being attached to the left arm. The light troops were also provided with bows and arrows, and slings, which they used in skirmishing at a distance. The *pilum* or heavy dart, intended to serve principally as a missile, was originally borne by the *triarii* alone, whence the name of *pilani*, but was afterwards appropriated to the *hastati* and the *principes*. Its shaft was of such a thickness as to be easily grasped by the hand;[6] and the weapon, including both wood and iron, was about seven feet in length. The iron, however, was of the same length as the wood, extending to the middle of the shaft, which was firmly inserted in it, and made fast by nails driven transversely; and it was of a square form, of an inch

[1] *Decline and Fall of the Roman Empire*, vol. i. chap. iii. p. 13, 14, 8vo ed.

[2] "The turma of the Romans," says the Count von Bismark, "had, according to Vegetius, eight files and four ranks; *ten turmæ formed a legion*; the distances between the turmæ were equal to their front." (*Cavalry Tactics*, p. 273, Engl. transl.) It would be curious to learn in what edition of Vegetius the Count discovered that the *turma* of the Romans had eight files and four ranks, and that ten *turmæ* formed a *legion*, or brigade of *infantry* and *cavalry* united in very unequal proportions. Unless the Count has found out something to which the Romans themselves were strangers, he must have fancied that, in describing the formation of the infantry of the legion, Vegetius was speaking of the cavalry.

[3] When the Roman soldiers threw their *pila* or heavy darts, they had the left leg foremost; but when they engaged in close combat with the sword, they were taught to advance the right leg, which was accordingly protected by the iron-covered greave or boot above mentioned. (Vegetius, lib. ii. cap. 15 and 16; Justus Lipsius, lib. iii. dial. 2, *De Mil. Rom.*; Guischardt, tom. ii. p. 160.)

[4] The *gladius Hispaniensis* is thus described by Polybius:—Ἁμα δε τῳ θυρεῳ μαχαιραν, ταυτην δε περι τον δεξιον φερει μηρον. Καλουσι δε αυτην ΙΒΗΡΙΚΗΝ· εχει δε αυτη κεντημα διαφορον, και καταφοραν εξ αμφοιν τοιν μεροιν βιαιον, δια το τον οβελισκον αυτης ισχυρον και μονιμον ειναι. The name of this weapon sufficiently indicates its origin. An unknown writer, quoted by Suidas, says that "the Celtiberians excelled all others in the manufacture of swords, strongly-pointed and double-edged; wherefore the Romans, laying aside the swords which had been in use among their ancestors, replaced them, in the time of Hannibal, with the Spanish blades. But (he adds) although they assumed the form, they were unable to imitate the temper of the steel and the beauty of the workmanship." Josephus says that, in his time, the Romans had two swords—one of considerable length, which hung at the left side, and another about a foot long, which they carried on the right thigh; in other words, a sword and a dirk, like the Scotish Highlanders. Similar changes in the arms of the soldiery may be remarked every century.

[5] The Romans invariably gave the point, and derided the practice of those who depended on the cut rather than on the thrust. "Præterea non *cæsim*," says Vegetius, "sed *punctim* ferire discebant. Nam cæsim pugnantes non solum facile vicere, sed etiam derisere Romani. Cæsa enim quovis impetu veniat, non frequenter interficit; cum et armis vitalia defendantur, et ossibus. At contra puncta, duas uncias adacta, mortalis est. Deinde dum cæsa infertur, brachium dextrum latusque nudatur. Puncta autem tecto corpore infertur, et adversarium sauciat ante quam videatur." (*De Re Militari*, l. i. c. 12.) This, we believe, is still accounted sound doctrine of fence.

[6] This seems to be the meaning of the Greek word παλαιστιαιος, applied by Polybius to the shaft or helve of the *pilum*; for, taking it in its ordinary acceptation, the shaft of the *pilum* would have been four inches in diameter; a size which, considering the length of the weapon, and the weight of its iron, would have rendered it an impracticable arm. Dionysius of Halicarnassus confirms this opinion by describing the *pila* as χειροπληθη or weapons that completely *fill the hand*. Polybius compares this formidable arm of offence to a boar-spear.

and a half at its greatest thickness, but its diameter gradually diminished to the point, which was exceedingly sharp, and near to which was placed a hook or barb, that served to retain the weapon wherever it penetrated. Besides this arm, which was necessarily heavy, the soldiers were sometimes provided with another of the same kind, but less massive both in the wood and the iron, which they held in the left hand, and discharged immediately after the former. The *pilum* was a weapon peculiar to the Romans. As soon as they came within a proper distance of the enemy, they began the combat by launching these heavy darts, with a force which, from their weight and the temper of the steel points, caused them frequently to penetrate both buckler and cuirass, so as to inflict the most hideous and desperate wounds. Having discharged these missiles, the legionaries instantly drew their swords and rushed upon the enemy with the utmost impetuosity, before he could recover from the effects of the volley of *pila*, by which his first ranks were generally overthrown.[1] The pike of the *triarii*, a weapon equally adapted for attack or defence, onset or resistance, was longer, less thick, and consequently more manageable, than the *pilum*, which was of little use except at the moment of commencing battle. Armed with this weapon, the veteran reserve of the legion often awaited *de pied ferme*, the shock of cavalry as well as infantry; and Livy assures us that they seldom or never quitted their pikes in battle. "The *triarii*," says he, speaking of a particular occasion, "disfigured the faces of the Latins with their pikes, the points of which had been blunted in the combat." These *troupes d'élite*, therefore, may be considered as the pikemen of the legion; although instances are to be found where they abandoned the pike and had recourse to the sword, which was always the weapon in which the Romans placed the greatest confidence, and with which, indeed, their most celebrated feats in arms were achieved. It may be proper to add, that, although this description principally applies to the legion as constituted in the time of Polybius, and although great changes were subsequently introduced, yet the arms, offensive as well as defensive, of the legionaries, remained nearly the same; with this exception, however, that all the troops of the line were at length armed in precisely the same manner, namely, with the Spanish sword and the *pilum*.

The horse had very nearly the same armour as the foot, and they were latterly provided with offensive arms similar to those used by the cavalry of the Greeks; namely, with a lance, having a shaft resembling two cones joined together at their bases, and pointed at both extremities, and a long, large sword, suspended by a shoulder-belt at the right side. There was a time, indeed, when they had only slender lances, pointed at one extremity, and wore no cuirass; but experience soon showed the necessity of adopting the Greek arms and equipments. The Roman cavalry was generally composed of a superior description of men, denominated knights, who on all occasions displayed the greatest valour; but they seldom mustered in force sufficient to produce great results, and their organization appears to have been in many respects defective.

It is evident, that a man placed on the back of a horse, without a saddle, or stirrups to serve as a fulcrum for reaction, can never exert half his proper force, nor combine it effectively with the momentum acquired from the velocity and weight of his horse. "Ces cavaliers," says Rogniat, "ne pouvaient être choisis que parmi les chevaliers, qui formaient un des premiers ordres à Rome. L'état leur fournissait ordinairement des chevaux; mais, peu habitués à l'équitation, ou persuadés qu'on est plus fort à pied qu'à cheval, ils mettaient souvent pied à terre, pour prendre une part plus décisive aux combats sérieux. Telle était (he adds) l'opinion des Romains, de la supériorité de l'infanterie sur la cavalerie, que, non content de n'avoir qu'un petit nombre de cavaliers, ils les transformaient encore en fantassins dans les occasions critiques."[2]

The Roman generals, even in the time of the consuls, do not seem to have followed any particular order of battle, but to have changed it according to circumstances, or the nature of the enemy they had to contend with. This is evinced by the various dispositions which were made at the battles of Tunis, of Cannæ, of Zama, and many others that might be mentioned. But still the chequer order or *quincunx* was that most frequently employed in the earlier times of the republic; owing, doubtless, to the facility it afforded of forming line or column at pleasure. Leaving the *velites* or light troops out of view, as constituting no part of the main battle, the reader will observe that the manipules of the first line, or the *hastati*, were formed upon a front varying according to the depth, which was generally ten, but not unfrequently six; and that the interval between each manipule was exactly equal to its front. Thus, supposing the legion 5000 strong, a manipule of 140 men would be ranged ten deep upon a front of fourteen; and as each soldier occupied three feet,[3] the extent of front presented by a manipule would accordingly be fourteen yards. Since the first line, therefore, consisted of ten manipules, it contained of course nine intervals of fourteen yards each; exactly opposite to which, but at a considerable distance in the rear, were stationed nine of the ten manipules of the second line, or *principes*, drawn up in the same manner as those of the first, upon fronts of equal extent; the tenth manipule of the latter outflanking by the whole length of its front the right or the left wing, as it might be, of the first line. The *triarii*, of less depth than the *hastati* and *principes*, but for the most part in continuous formation, occupied the third line. Now, it must be obvious at the first glance, that this order of battle presented several important advantages. By advancing the manipules of the *principes* through the above-mentioned intervals, until they dressed with those of the *hastati*, line was at once formed: again, by moving them fourteen yards either to the right or left, the depth of the formation was doubled; while, by placing the manipules of the *triarii* exactly behind those of the *principes*, as was done when the legions were menaced by elephants, the whole was formed into columns, separated into intervals equal to their respective fronts, through which these animals, pursued and goaded by the *velites*, might be driven to the rear, without doing

[1] For a particular description of the use of the *pilum* in commencing the attack, see Cæsar's *Commentaries de Bello Civili*, lib. iii. cap. 92. The weight of this arm "ne permettoit pas de le darder de loin," as Guischardt says. It was the business of the *velites* to harass the enemy with their javelins and other missiles before the action became general. As the hostile lines approached, the light troops retired through the intervals or by the flanks, where they generally took their station; and when the former were within a short distance of each other, the *hastati* and *principes* darted their *pila*, and then rushed on, sword in hand, to close combat. Hence the proverb employed by Vegetius to describe the proximity of two armies: *Ad pila et spathas ventum est.*

[2] *Considérations sur l'Art de la Guerre*, p. 10, 11. Paris, 1820.

[3] The ranks of the manipule being also drawn up at the distance of three feet from one another, the whole space occupied by the Roman soldier was consequently nine square feet of ground; and this open order was seldom departed from, even in the charge. It is to be observed, however, that the second rank of the manipule was so disposed as to cover the intervals of the first, the third to cover those of the second, the fourth to cover those of the third, and so on to the last; in other words, the arrangement of each manipule individually was a precise type of their collective disposition in order of battle.

any mischief. Lastly, if it was desired to form the legion in three continuous lines, this was instantly effected by simply closing up the intervals between the manipules of the first and second lines; the *triarii* or reserve being, as we have already said, drawn up in a continuous formation, except when it became necessary to open a passage for elephants. And all these various evolutions were performed with a rapidity and precision which have seldom been equalled and never surpassed by the troops of any other nation.

At a later period, however, the Roman tacticians employed a different order of battle, distinguished for its greater compactness and solidity, as well as for the facility and rapidity with which it might be formed from the order of march, even in presence of the enemy. According to this method each manipule of the legion formed only a single rank in its order of battle; consequently the two classes of *hastati* and *principes*, ranged each upon its first manipule as a front, formed two lines ten deep. But as each man occupied three feet every way, and as the lines were separated by an interval equal to half the extent of their front, it is obvious that each line occupied a front of 120 yards, by from ten to twelve yards in depth; and that they were separated from each other by an interval of about 60 yards. Again, at an equal distance in rear of the *principes*, the *triarii* formed the reserve of the legion in the third line; and the whole, ranged in this manner in three lines, constituted a square order, as deep as it was broad; while the *turmæ* of the cavalry covered the flanks of the lines, and the eagle or standard of the legion was intrusted to the keeping of the *primipilus* on the right of the line of the *triarii*. This order, usually denominated *legio quadrata*, was that adopted by all skilful generals when in presence of an enemy. But the different legions composing an army were ranged upon the same principle, with reference to one another, as the different ranks of the same legion; in other words, they were formed *en echelon;* each legionary line thus making one of the sections of the column, and the baggage occupying the intervals, while the *velites* covered the flanks. In this order of march, if the enemy threatened an attack on the front, each legion in succession formed line with that at the head of the column; the second almost in an instant, the third somewhat later, and the fourth, or the most remote, in about seven minutes, which were accounted sufficient for developing the order of battle on the front. But the order of battle on the flank was of still more rapid formation. For, the baggage withdrawing from between the sections, and assembling on the side opposite to the enemy, each legion executed what is technically called a *quart de conversion* on its *hastati*, and the whole army immediately found itself in order of battle; two minutes being sufficient for the performance of this simple evolution. It seems evident, then, that the celebrated *quadratum agmen* of the Romans, which has hitherto been so often treated of, and so little understood, consisted of a certain number of *legiones quadratæ* disposed *en echelon*, or at least in column, as we have just described: and, from the advantages of this order of march, particularly its rapid convertibility into an order of battle either on the front or the flank, it is easy to understand the reason why the Roman historians have censured so severely the generals who neglected to adopt it in presence of the enemy. So much, then, for Roman tactics, as connected with the elementary formation of those brigades or divisions which constituted the units of Roman armies.

The distinguishing characteristic of the legion consisted in its astonishing mobility, united with its power of preserving its order of battle undisturbed, and of constantly rallying when forced to give way. It possessed a sort of flexibility which enabled it to adapt itself to every change and variety of circumstances; and no other military body, perhaps, ever executed so numerous evolutions in the presence of an enemy. Its attack was impetuous and formidable; but if that failed, it then displayed its most characteristic excellence, by fighting in retreat. In this way it vanquished the phalanx, although it was unable to withstand the direct shock of that dense body in the open field. At the battle where Flaminius defeated Philip in Thessaly, the Macedonian phalanx gained considerable ground on the legions; but the Romans, although forced to give way, preserved their order,—returned repeatedly to the charge,—and, even while in the act of retiring, extended their line so as to gain the flank of the Greeks. Philip durst neither accelerate his march, nor send out any detachment in pursuit; so that twenty manipules had time to turn his flank and fall upon his rear, which speedily decided the fate of the battle. As the phalanx acted with long pikes, and in close order, the least derangement caused by the ardour of the soldier in pursuit, or by inequality of ground in its march, necessarily exposed it to the legion; which, dividing itself into a number of separate corps with the same facility that it formed one corps and one line, possessed the power of attacking it on two or more sides at the same time. "La légion doit donc," says Guischardt, "être envisagée sous deux faces. Comme infanterie en bataille contre une autre infanterie, elle eut son ordonnance particulière à rangs et files ouverts, conformément à ses armes; et alors elle n'eut rien de commun avec la phalange. Lorsqu'elle a eu de la cavalerie en tête, elle cessa d'avoir son ordonnance particulière."[1] This wise distinction rendered the legion formidable alike to every nation on which Rome chose to make war;[2] but neither as infantry against infantry, nor as infantry prepared to resist cavalry, which duty was principally performed by the *triarii*, until all distinction of classes and arms merged in a homogeneous formation, had it any thing in common with the phalanx; for its victories, no less than its reverses, had demonstrated the inutility of deep formations, and showed that its real power depended on its distributive rather than its concentrative energies,—on its mobility and flexibility rather than on its weight or impulsion. Hence, on the day of Pharsalia, it was remarked, as an extraordinary circumstance, that Pompey had formed his legions ten deep; a novelty which, as every schoolboy knows, served no other purpose, on that occasion, except to add to the carnage.

In following the Romans in their wars under the emperors, we find their discipline and their tactics declining from age to age, in the same manner as they had advanced and improved. The spirit of change, though productive of some ameliorations, proved ultimately fatal to the legion. As long as the Romans continued faithful to the precepts and rules of the ancient masters, their infantry maintained its superiority: in proportion as these were departed from it declined; until at length, having lost all its distinctive qualities, it was constantly beaten and overthrown by the numerous cavalry of the barbarians. To ascribe the gradual declension and ultimate fall of this infantry to luxury, refinement, love of ease, corruption of

[1] *Mémoires Militaires*, tom. i. p. 84.

[2] The cavalry of the Parthians, though peculiarly formidable, durst not attack the legions commanded by Marc Antony, and confined itself to harassing them from a distance with its arrows. At the battle of Nicopolis, a single legion of the army of Domitius defeated and put to flight the whole cavalry of king Pharnaces; and, with a handful of infantry and some horse, Pompey defied the numerous cavalry of king Oroses.

Army. manners, or other analogous causes, is merely to indite silly common-places, displaying the most profound ignorance of history and of human nature. Its catastrophe was occasioned by the decay of discipline alone. For experience shows that hardy and effective soldiers may be formed in the most polished as well as in the rudest and most uncivilized periods of society; and that nothing more is necessary to produce this result than an uncompromising system of discipline. Accordingly, under Vespasian, and Titus, and Trajan, and Hadrian, and Aurelian, and other warlike emperors, who enforced the precepts of the ancient masters, and restored the ancient discipline, the Roman infantry regained its reputation, and proved itself as formidable as it had ever been in the best times of the republic. The corruption was not in the soldiers, but in the men by whom they were organized; in those whom the experience of so many ages, and the conquest of the world, had failed to impress with a due conviction of the value of that system of discipline by which such prodigies had been performed. "On ne peut voir sans indignation," says Guischardt, "la mauvaise ordonnance que les Romains au tems de Végece avoient substituée aux anciens modèles. Ils étoient rangés sur six de hauteur, et même quelquefois sur trois. Chaque rang avoit des armes différentes, dont la plupart étoient des armes de jet, comme des arcs et des frondes. D'un rang à l'autre il y'avait six pieds d'intervalle, et dans les files on avoit retranché les trois pied de distance, parcequ'on ne se battoit plus avec l'epée: on avoit même oublié le véritable usage du *pilum*. Le troisième et le quatrième rangs dévoient de tems en tems se détacher, et charger à la tête de la ligne, et revenir ensuite à leur poste. On ne sauroit rien imaginer de plus pitoyable. Ces deux chapitres de Végece marquent bien clairement l'ignorance de l'auteur, et la décadence de la bonne discipline chez les Romains."[1] From innovations like these, and others still more absurd which succeeded them, what results could be anticipated except those which history has recorded; namely, disgraceful defeats, calamitous reverses and, at length, the final overthrow of the Roman power itself? The legions, degenerated into a feeble militia, sold the empire which they were incapable of defending; and having neither the courage which sometimes supplies the place of discipline, nor the discipline which supplies that of mere courage, they fell an easy prey to the swarms of Goths, Huns, and Vandals, by whom it was successively overrun, and at last completely destroyed.

Armies of the middle ages.

The fall of the Western Empire, like that of a colossal structure, was succeeded by a thick cloud, which overspread Europe, covering it with darkness and desolation. All that remained of science or of art perished in its ruins, and the only relic of the catastrophe was the shadow of a mighty name. But the barbarians who had subverted the Roman power appear to have brought with them, from their forests and wildernesses, the elements of a system which was destined to thicken the darkness in which it originated; to bind Europe for ages in the fetters of the most abject thraldom; nay, even to maintain a long and fierce struggle against the reviving energies of the human mind, and the regenerative powers of society. Its foundations were laid in their peculiar character and habits, as affected by their position and their wants; and, as they had fought neither from the love of glory, to which they were insensible, nor from a thirst of vengeance, which nothing had contributed to stimulate, the only fruits they dreamt of reaping from victory were the spoils of the vanquished. The countries which all had conquered were considered the property of all, and each claimed a share proportionate to his services and the number of his retainers. Subsisting rights or possessions weighed as nothing in the estimation of these wild hordes, who sought for establishments in genial climates and fertile regions. They demanded a territorial division and apportionment, which was accordingly made upon some rude principle of equalization. But, as these lands were the reward of military service, so they were to be held by that tenure alone. The common interest and the common defence required that this condition should be annexed to the allotment, or, as it was afterwards called, the *feu*. Each great vassal of the liege lord was bound to have in constant readiness to take the field, a certain number of men, clothed, armed, and equipped at his own expense. Hence arose the *feudal system*, which, founded on military rather than civil principles, was an aggregation of petty sovereigns and petty principalities, under a nominal head, to whom all swore fealty, but few or none owned obedience; a military aristocracy, in short, under the mask of a monarchy. But this system, however well calculated to keep alive a spirit of ferocity, seemed to oppose a formidable barrier to the revival of the military art. Its maxims, necessarily hostile to the establishment of a standing army, by which the great barons might have been coerced, limited the force of the state to the contingents of feudal militia, which the crown vassals could bring into the field; a tumultuary mass, without coherence, which the first victory or the first reverse generally dispersed. During this period, accordingly, the wars of Europe were desultory and indecisive. An incursion constituted a campaign, and a foray an expedition. Armies were everywhere without order and without science; battles were gained by accident or by valour, never by discipline; while conquests, rapid as torrents, were generally as destructive and as transitory. The love of military glory was extinguished; petty wars, occasioned by baronial feuds, raged fiercely, preying upon the vitals of society; and the fruits of organized barbarism were general misery and desolation. The people were abject serfs, the barons ferocious brutes, the sovereign an absolute cipher. Anarchy, tyranny, ignorance, and spiritual thraldom, formed the characteristics of the first ages of feudalism.

The crusades.

At length, in the eleventh century, arose a monk, called Peter the Hermit, who preached with all the fervour, and more than all the success, of any known apostle, the duty of recovering the Holy Sepulchre from the infidels; and as the church lent her powerful aid to second the efforts of Peter's enthusiasm, the contagion soon spread throughout every part of Europe, and thousands of all countries rushed forward to enlist under the banner of the cross. The history of mankind affords no parallel to the madness that was thus produced, either as regards its universality or its duration. It affected all Christendom in nearly an equal degree; and, during two centuries, army after army marched for Palestine, to melt away under the sultry sun of Syria, or to be mowed down by the swords of the Saracens. But it agitated the minds of men by a new and powerful impulse; and although its essence consisted in the wildest fanaticism which had ever taken possession of the species, yet that inexplicable frenzy, combining with a spirit of enterprise and adventure, gave birth to institutions which were destined to exert a powerful influence upon the whole frame of society, and which have left a marked impression even on the manners, customs, and feelings of modern times. Viewed in a military light, the armies of the crusaders were mere

[1] *Mémoires Militaires*, prel. disc. xxiv.

tumultuary masses, impelled by fanaticism to deeds of heroic valour, but as destitute of order and discipline as their leaders and chiefs were ignorant of military science; nor had all the reverses they sustained the effect of inculcating the simplest principles of the art of war, or teaching the necessity of adopting some kind of organization. Every thing was trusted to numbers without combination, and to individual bravery exerted as chance or impulse happened to direct. And so deeply engrained in men's minds was the spirit of feudalism, and so incompatible did that spirit show itself with the slightest advancement in the military art, that the mailed chivalry of the ages immediately succeeding the crusades, although offering the finest elements that ever existed for the organization of an invincible force, appears at no time to have had any principle of effective combination, or to have been capable of acting with unity and concert in any grand operation. Yet the principal strength of armies in the middle ages consisted in their cavalry; which, composed of men of superior grade, and formidable from its bravery no less than from the armour of proof in which it was encased, easily proved itself superior to infantry without formation, and with no other discipline than that which instinct dictates even to the most barbarous tribes.

Invention of gunpowder.

But a new epoch approached. Gunpowder was invented, or at least improved, by Berthold Schwartz, a Franciscan monk of Cologne, and was first employed in warlike operations in the early part of the fourteenth century. This discovery, as Guibert justly remarks, did not lead to any *immediate* improvement in the art of war: indeed a century and a half was necessary in order to make the use of fire-arms general; but it is nevertheless to be considered as the real cause of the complete reform which was at last effected in the constitution of armies, as well as in their discipline and tactics. Since the first employment of gunpowder, there have been *seven principal periods* in the history of the military art.

First period.

The first begins with the employment of cannon, and extends to Charles VIII.'s campaign in Italy; or from the early part of the fourteenth until towards the end of the fifteenth century. This period, during which the art of war began to revive from the state of barbarism into which it had sunk since the downfall of the Roman empire, includes the wars of the Spaniards against the Moors, of the English against the French, and finally, of the Italian republics against each other. The cavalry, composed of the nobility and gentry, still constituted the flower of armies, and formed the chief support of princes and their kingdoms. At the storming of fortresses, or when important posts were to be occupied and defended. and a bold, determined soldiery was required, the knights dismounted and fought on foot. They were the dragoons of that age. Each knight was attended by his esquire; and, besides these there were also archers, generally the vassals of the knights, who, being more lightly armed, and riding smaller horses, served as a kind of light horsemen. At the beginning of the fourteenth century, indeed, the distinction of heavy and light horse was common in European armies. The former, consisting of tenants *in capite*, holding of the crown by tenure of military service, or their substitutes (*servientes*), were denominated *men-at-arms*, from their being armed *cap-à-pied;* the latter, composed of yeomen, were named *hobilers*. The knights rode what were denominated war-horses, which, like their riders, were covered either with chain or plate armour, or with both; and these men of iron carried a long and powerful lance armed with an iron head, a long sword, a short sword, a dagger, and a mace or battle-axe.[1] Their formation for combat was exceedingly simple. They fought man to man; each armed knight singling out his opponent, and riding against him with his couched lance, in order to throw him out of his saddle, or to make him prisoner. The esquires, or armour-bearers, followed as a second rank, or at least acted as seconds to the knights, whom they assisted in battle, bringing them fresh arms and horses when required, and seeking opportunities of distinguishing themselves in order to obtain the honour of knighthood. Nothing, however, was known of scientific movements, until Charles the Bold compiled an exercise book in 1473, instructing cavalry how to attack in close and extended order, or to link the horses and fight on foot. An engagement was generally commenced by single knights riding forward and challenging opponents from the hostile army; and the result of these single combats sometimes determined the fate of the day.[2]

Second period.

The second period, from the campaign of Charles VIII. in Italy to the beginning of the wars in the Netherlands, or from the end of the fifteenth to the middle of the sixteenth centuries, comprises the wars of the French, Spaniards, and Germans, in Italy. During this period chivalry gradually declined, and war began to assume a new aspect. At the close of the contest with England in 1445, Charles VII. of France established the first standing army, consisting of 16,000 infantry and 9000 cavalry, divided into fifteen *campagnies d'ordonnance;*[3] he appropriated funds for the payment of these troops, and appointed officers to discipline and command them; and, although apprehensive at first as to the success of the experiment, he at length succeeded in organizing a force, which enabled his successor to repress the turbulent spirit of the feudal aristocracy, to strengthen the power of the crown, and to carry on foreign operations with a consistency and vigour hitherto unknown. The Italian campaign of Charles VIII. proved the superiority of a standing army over an assemblage of feudal militia, and consequently established its reputation. With a force of about 20,000 men, he overran the whole of Italy; and, had his ambition been equal to his success, or rather had he known how to reap the fruits of victory, he might have rendered himself permanent master of that country. Other nations imitated the example of France: a change took place in the military system of Europe: the practice of calling out knights ceased of itself: and mercenary, or at least paid troops, regularly disciplined and organized, became the only force that was trusted or employed. The characteristic of this period was deep formation, both in the cavalry and the infantry.

Third period.

The third period comprehends the great war of independence, carried on by the Netherlanders, in order to emancipate themselves from the yoke of Spain; and it extends from 1568 to the general suspension of hostilities in 1609. Here fought, on one side, art, and an army formed by the experience of more than half a century of war, under Charles V. and his son Philip II.; on the other, the inhabitants of the Low Countries, living only by trade and the arts of peace. A people, consisting chiefly of manufacturers and merchants, inhabiting a country of small extent, and already much exhausted by a long-continued exercise of tyranny and oppression, scrupled not

[1] Meyrick's *Critical Inquiry into Ancient Armour*, vol. i. p. 174. Chain-armour first became covered with plates at the beginning of the fourteenth century; but entire plate-armour did not make its appearance until about a century after.

[2] The only military productions of this period were the regulations of Charles the Bold, above-mentioned, with those of Louis VII. of France, and of John Ziska, general of the Hussites.

[3] See Père Daniel, vol. i. p. 155.

to draw the sword, in defence of their liberties, against the richest monarch of the age, the sovereign of Spain and the Indies, and master of the most numerous as well as the best-disciplined forces, commanded by generals distinguished above their contemporaries by their skill in the art of war.[1] A more unequal contest cannot well be imagined; and never was the issue of any dispute more contrary to what the parties had reason to anticipate. But the struggle was protracted; and in proportion as the Netherlanders were formed to war, the bravery and discipline of the Spaniards relaxed. Under the skilful tuition and able conduct of Nassau, the foe which had at first appeared so contemptible to the haughty Spaniards, tore the laurels from their brows, and at length drove them, defeated and disgraced, from the country which had suffered so long under their grinding oppression and their insolent misrule. This war was followed by great changes, both in the organization and tactics of armies. The cavalry was divided into cuirassiers and light horse; the use of the lance was discontinued,[2] and its place supplied by the sword and pistol for the heavy, and the carbine for the light horse; and these were now trained to execute a variety of movements and manœuvres at full speed. The infantry was also placed upon a better footing, both in respect to discipline and formation; although the prejudice in favour of columns or masses seems still to have continued, notwithstanding frequent experience of their inutility, as well as of the destruction to which they were exposed from the concentric fire of artillery.

Fourth period.

The fourth period comprises the Thirty Years War, the pretext for which, according to Bulow, was the happiness of heaven, but the motive the goods of the earth: it extends from 1618 to 1648. The peace which had terminated the struggle for independence in the Low Countries, after a protracted contest of above half a century in duration, lasted only nine years; when a new war broke out, which can only be considered a continuation of the former. The hero of this war was Gustavus Adolphus; and he, like Prince Maurice of Nassau,[3] was the creator of new tactics. This warlike monarch departed from the dense formation of his predecessors, and drew up his infantry six deep; which was considered an innovation that nothing but his success could justify. His opponents, Tilly and Wallenstein, formed their infantry in solid masses thirty deep; which, nevertheless, proved unable to contend with the linear formation of the Swedish troops. Until about the middle of this war, it still continued the practice to form cavalry in from four to eight ranks. But Gustavus also departed from this rule, and formed it in three ranks; although it appears from Harte, that, at the battle of Leipsic, it was drawn up four deep, probably on account of the dense formation of the imperial cavalry, which was formed in eight ranks. In the intervals he stationed platoons of infantry, fifty and upwards strong, as well as light guns; doubtless from a conviction that cavalry, unless supported, were unable to contend with infantry. His great object appears to have been, to give greater mobility to the two principal arms of a military force, and thus to gain in celerity of movement what he had lost in weight or impulsion. He knew that the momentum would remain the same, if the motion was increased proportionally to the diminution in weight.

Fifth period.

The fifth period comprehends the wars of the French in Italy, in Germany, and in the Netherlands, as well as the northern and Turkish wars, and embraces a period of ninety years; namely, from 1648 to 1738. The peace of Westphalia put a period to nearly a century of war. The results of this conflict were the secularization of ecclesiastical property, the complete establishment of the Protestant religion, the recognition of mental freedom, the decay of the Papal power throughout Europe, and the triumph of national independence. But during the long-continued struggle in Germany, two hereditary enemies appeared,—the Turks and the French. The former were expelled in a single campaign, and never again attempted any serious invasion. The latter entered upon a series of wars of which we have not yet probably seen the termination. The ambition of Louis XIV., however, and the wars to which it gave rise, rapidly developed the art of carrying on military operations, and formed generals whose names adorn military history. Opposed to a French Turenne, Luxembourg, and Condé, stand Montecuculi, Marlborough, and Eugene of Savoy; Louis of Baden may rank with Catinat or Vendôme; and many other generals of eminence illustrate this period, which was less remarkable for changes in the constitution and organization of armies than for the talents displayed in conducting their operations in the field. It was the era of great commanders. In the north the Swedes, Poles, Brandenburgians, and Muscovites, fought alternately on the plains of Poland and the steppes of the Ukraine. Under Charles XII. the Swedish infantry attained a high degree of perfection, and proved uniformly successful until it was so rashly committed at Pultowa; while the cavalry, without defensive armour, which the chivalrous monarch rejected, consisted almost entirely of dragoons.[4] The principal improvements of this period, however, are chiefly due to the French, who made rapid advances in all the branches of military science.

Sixth period.

The sixth period includes the three Silesian wars namely, from the beginning of the first Silesian war in 1740, to the breaking out of the French revolutionary war in 1792. For a century previous to this, Prussia appears to have been chiefly employed in preparing herself for the brilliant part which she acted under Frederick II. To the celebrated elector, Frederick William, the Prussian military power in a great measure owed its origin. This prince grew up, as it were, in a camp, and, even in his boyish days, was present at the sieges of Breda and the Schenkenschantze. Arrived at the government, he endeavoured to infuse a new spirit into the army; and so well did he succeed, that, in 1672, he was enabled to promise the republic of Holland an auxiliary force of 20,000 men. At the period of his death the elector left behind him a well-organized army of 30,000. When Frederick the Great (or, as he

[2] "La lance," says Montecuculi, "est la reine des armes pour la cavalerie." (*Mémoires*, liv. i. c. 2.) And this opinion seems to be gaining ground at the present day; for experience has shown, that cavalry can never make any serious impression by means of firearms, while, with swords alone, they are wholly unfit to contend with infantry.

[3] Bismark's *Cavalry Tactics*, p. 307; Guibert, *Essai Général de Tactique*, p. 68.

[4] Charles XII., not content with making the cavalry, without any connection with or dependence upon other arms, but from confidence in itself, charge the enemy's horse at full speed, without firing, led it equally against intrenchments and batteries, and always with success. "He knew," says Count Bismark, "that by the rapidity of motion, the natural vivacity of the majority of mankind is increased, and, often mounting to a blind fury and foolhardy enthusiasm, leaves no time for consideration or calculation of danger; that at such a moment death loses its terrors, and *Victory!*—but with living colours—presents itself to the soul of the wildly-rushing warrior." (*Cavalry Tactics*, p. 319, 320, 321.) At the same time Charles appears to have had a love of fighting for its own sake; and it was probably this peculiarity of temperament, as much as any calculation of results, which gave to his movements that impetuosity, which neither natural nor artificial obstacles could check or resist.

Army.

is called by the Germans, *der Einzige*, the Unequalled) ascended the throne, he found the army about 80,000 strong, and drilled to a precision of movement, as well as a rapidity in firing, until then unknown. This was owing to the exertions of Prince Leopold of Dessau, who may be considered the founder of the modern system of tactics, having invented the iron ramrod and the equal step,—reduced the formation of the infantry from four to three ranks, thereby increasing the effect of musket fire,—and, in short, laid the foundation of the system which Frederick afterwards improved, by giving to infantry-movements greater lightness and facility. With an army thus prepared for action, Frederick took the field in 1740. But the first two wars passed quickly by; and the intervals of peace were employed in reforming whatever experience had shown to be defective in his system,—in practising a vast variety of deployments,—and, above all, in introducing that celerity of movement which had become so essential in modern armies, with reference both to their numbers and the extent of their front. When the third Silesian or Seven Years War broke out, Frederick, forsaken by his allies, and menaced on all sides by powerful enemies, seemed on the very verge of destruction. But if he stood alone, he stood unmoved, like the oak, braving the storm, and conscious of the power to weather it. Nor was he without some peculiar and decided advantages. On the one hand, his natural *coup d'œil*, which was perfect; the unity and power of his will; the habit of his troops to remain firm in all situations, and to execute every movement with precision, even in the very tumult of battle; the never-shaken confidence in their leader, and the enthusiasm with which he was regarded by them: and, on the other, the division, weakness, and want of system or connection in the enemy's plans of operation; their partial and lukewarm mode of execution; together with the inferiority of their troops in organization, and of their commanders in genius:—these were the causes which enabled Frederick to retire from this bloody seven years conflict with a prodigious increase of fame, and without the loss of an acre of territory.[1] "Depuis la guerre de la Succession," says Guibert, "on n'avoit pas vu tant d'armées en campagne et réunies contre un seul prince. Sa science et leurs fautes furent le contrepoids de tant de forces. Jamais guerre ne fut plus instructive, et plus féconde en événemens. Il s'y fit des actions dignes des plus grands capitaines, et des fautes dont les Marsin auroient rougi. On y vit quelquefois le génie aux prises avec le génie, mais plus souvent avec l'ignorance. Partout où le roi de Prusse put manœuvrer il eut des succès. Presque partout où il fut réduit à se battre, il fut battu: événemens qui prouvent combien ses troupes étoient supérieures en tactique, si elles ne l'étoient pas en valeur."[2] Such was the character of the Prussian army of this period, and such the military genius of the great monarch by whom it was commanded. Mere tactical details are foreign to the object of this article, and therefore we abstain from entering into them, excepting in as far as they may seem necessary to throw light upon the constitution and composition of armies. That of Prussia was long considered a model for imitation. Under Generals Siedlitz and Ziethen its cavalry attained a degree of perfection unequalled either before or since. "There was but one Seidlitz," says Count von Bismark. In playing the mighty game of war, its infantry was also superior to any other of that age; and if subsequent events somewhat tarnished its reputation, it has never ceased to be one of the best organized and most completely equipped bodies of foot in Europe. The Austrians, as their wont is, only improved on compulsion, and when fairly beaten out of their old system of masses and deep formations.

Seventh period.

The armies and the science of this period, however, were destined to be far outnumbered and surpassed in the seventh and last, which embraces the military systems and establishments of our own times. These, accordingly, we shall now proceed to describe in detail; confining our accounts principally, if not exclusively, to their actual rather than to their former condition and strength; and commencing with the army of France, which has not only played a most conspicuous part since the commencement of the revolutionary wars, but has latterly served as a sort of model on which the other armies of Europe have been more or less formed.

French army.

From time immemorial, the Gauls were inhabited by a race of men distinguished for their bravery. Hardy and enterprising under the two Brenni, obstinate and persevering in their attacks against Cæsar, we find them cutting a conspicuous figure as auxiliaries in all the wars of ancient Rome. They passed through the middle ages with equal distinction; and if they were forced to yield to the irruption of the Franks, the amalgamation of the two nations had only the effect of adding to their energy. The wars of Charlemagne and the crusades; the successive invasions of Italy by Louis XII., Charles VIII., and Francis I.; and, lastly, the struggles maintained against all Europe by Louis XIV., showed what might be expected from French armies when properly commanded. But the fatal results of the Seven Years War, the wretched intrigues of the court of Louis XV., and still more the spirit of infatuation which appears to have become endemic after the disgraceful Hanoverian expeditions, eclipsed, in an instant, ages of glory, and rendered the army of France an object of ridicule to Europe. After the peace of 1762, some measures were taken with the view, as was pretended, of remedying the supposed defects in the constitution of the army, and restoring its character. But the French ministry of that day, ignorant of the real circumstances which had led to its successive defeats, and incapable of comprehending the dispositions and strategical movements by which success in war is attained, contented themselves with searching into the most minute details of discipline and instruction for the causes of failures which were solely attributable to a bad choice of generals, and a faulty direction of great operations. They imagined that the armies of Frederick had triumphed in consequence of oblique marches, the particular cut of their uniforms, and a thousand other absurdities which it would be impossible to credit, were not the amusing discussions of that period embodied in public documents of unquestionable authenticity; they disputed about ployments and deployments *en tiroirs*, about *tranches* and *plesions*, about a Prussian order and a French order; they formed camps in order to judge of the advantages of these different systems; and they fancied that they had discovered the sublime of the art in the mechanism of the instruction of platoons.[3]

[1] Bismark's *Cavalry Tactics*, p. 323.

[2] Guibert, *Essai Général de Tactique*, tome i. p. 77, 78.

[3] "On étoit si fort engoué de tout ce qui ressemblait à la tactique Allemande," says Jomini, "qu'il suffit á cette époque de porter un nom Tudesque pour faire une fortune militaire. Un certain capitaine Pirch, sorti des rangs de l'armée Prussienne, passa pour un émule de Frédéric, sur la simple présentation d'un mémoire dans lequel il donnait des idées pour aligner des bataillons sur les drapeaux; on se crut heureux qu'il daignât accepter un régiment et l'instruire suivant sa méthode." (*Histoire Critique et Militaire des Guerres de la Révolution*, tom. i. p. 214.) Under the government which promoted Pirch, and indeed under that which succeeded t Kléber, Moreau, and even Napoleon himself, would have been condemned to an eternal nullity.

"Encore un pas retrograde," says Jomini, "et les troupes Françaises se fussent trouvées au niveau des soldats du pape."[1] But the American war gave a check to these mischievous fooleries, and revived the spirit of emulation, which is the source of the most brilliant feats in war; while the expeditions to Grenada and St Eustatius, together with the campaigns of Lafayette, Saint-Simon, and Rochambeau, in a great measure restored the reputation of the French arms, and prepared the way for still more important achievements. The staff, the government, and the *faiseurs* were still divided between different systems. But while the chiefs were perplexing themselves with theories, the troops improved both in discipline and manœuvres; and had it not been for the repeated shocks which their organization experienced in consequence of frequent changes of ministry, and the introduction of certain radical innovations, which completely broke up the old battalions in order to amalgamate them with new levies, Louis XVI. would have possessed an army capable of defending the monarchy, and might have been able to restrain and resist that revolutionary frenzy to which he was destined soon to become a victim. In consequence of the disorganization thus introduced, the regiments of the line were in a wretched condition at the breaking out of the war in 1792. But a single measure saved them from destruction. The nomination officers taken from the *tiers-état* filled the ranks with an ambitious and warlike youth, burning to distinguish itself; while emulation, the chances of preferment, and the love of country, supplied for a time the want of discipline, and formed powerful motives for stimulating improvement.

At the end of the year 1791, the French infantry consisted of 105 regiments of two battalions each, 14 battalions of light troops, and 170 battalions of national volunteers; or 394 battalions in all. By the decree of the 5th May 1792, the number of the volunteer battalions was raised to 200, and the strength of each was increased from 226 to 800 men. The cavalry was composed of two regiments of carabineers, consisting of four squadrons each; 24 regiments of heavy cavalry of three squadrons each; 18 regiments of dragoons of three squadrons each; 12 regiments of chasseurs of four squadrons each; and 6 regiments of hussars of three squadrons each; in all 206 squadrons. So that the total strength of the French army at this period did not exceed 160,000 infantry, 35,000 cavalry, and 10,000 artillery; while 20,000 men were still wanting to bring the different regiments to their full complements. But this deficit was soon supplied by the multitude of volunteers who flocked to the national standards when the duke of Brunswick invaded France at the head of the Prussian army.[2] The revolution, however, had not yet developed its energies; nor had the world as yet any suspicion of the prodigies which the system of terror, afterwards organized, was destined to achieve. In 1795, France presented the formidable aspect of a vast camp. The decrees of the 23d August and the 5th September 1794 had hurried the whole youth to the frontiers. Nearly 1,200,000 men were in the pay of the republic; and, after deducting those employed in accessory services, and in the navy, the number of combatants in the field cannot have amounted to less than about 700,000. The official state of the force of the French armies, as at the 5th April 1794, presents an aggregate of 794,334 men, including garrisons, but exclusive of the army of the interior, whose head-quarters were at Paris; which, allowing one fifth for those in the depôts and for the sick, would give an effective force, present under arms, of at least 650,000 men; the most formidable which Europe had ever seen assembled in the field. "Ce dévelopement de forces, sans exemple dans les annales modernes," says Jomini, "tenait d'autant plus du prodige, que la nation se trouvait livrée à tous les déchiremens d'une guerre civile, et aux persécutions d'un gouvernement odieux. Mais ce ne fut pas aux levées seulement que ces efforts se bornèrent: tout ce qui compose les élémens de la puissance nationale, avoit été porté à un degré de tension inconnu dans les siècles modernes."[3] Nor did the "prodigy" stop here. In the month of March 1795, France had ten armies in the field, the active force of which amounted to 449,930 combatants, besides 120,850 in garrisons, and 388,450 sick, prisoners, or detached; in all 959,190 soldiers. But the active force, or number present under arms, did not form the half of the effective, and scarcely a third of the complete military strength of France at that period; for, as 200,000 men were still wanting to bring the effective force up to the full establishment, and as the most active measures were in progress to make up the deficit, the total number of Frenchmen under arms in 1795 cannot have fallen much short of 1,100,000 men. It will not be denied, therefore, that the *Comité du Salut Publique* possessed extraordinary energy, and that terrorism proved the salvation of France.

But this state of exertion was too violent to be of long continuance; and neither the population of the country, nor its exhausted resources, were sufficient to maintain so enormous a force in the field. Accordingly, in the succeeding years of the republic, the aggregate of the different armies seldom exceeded 480,000 effective men, and generally fell short of this number. But when Napoleon had mounted the throne, and had organized the system of conscription, he obtained an unlimited command over the whole of that part of the population capable of bearing arms; and as he acted upon the principle, first recommended by Cato, of making war support itself, he was not only able to repair the losses sustained in his various campaigns, but, on most occasions, to take the field with a predominating superiority of numbers. The establishment of the French army, in 1805, amounted to 341,412 infantry of the line, 100,130 light infantry, 77,488 cavalry, 46,489 artillery, and 5445 engineers; making a total of 650,964 men, or a force equal to that organized by the terrorists in 1794 and 1795. But this establishment was afterwards greatly increased; and it is calculated that, at the time of the Russian campaign, there were in the depôts, in the hospitals, and in the field, not less than 1,200,000 men, of whom about 850,000 might be considered as effective. Hence, we are enabled to account for the extraordinary phenomenon of Napoleon's appearance in Germany at the head of a new and formidable army, within a few months after the annihilation of his veteran masses amidst the steppes, snows, and frosts of Russia, and making head for more than a year afterwards against the utmost efforts of the allied powers.

One of the first cares of the Bourbons, on their second restoration in 1815, was to re-model the army, and place it on a footing adapted to the new order of things. The most obvious maxims of policy recommended a proceeding which alone could give stability to the restored dynasty. But such changes are necessarily the work of time; and we need not therefore wonder that nearly ten years should have elapsed before the important object was accomplished. The French army was re-organized, augmented, and placed on a new footing, in virtue of three royal ordonnances, dated the 27th February 1825; the first of which related to the infantry, the second

[1] *Guerres de la Révolution, ubi supra.* [2] *Ibid.* tom. i. p. 224–25. [3] *Ibid.* tom. v. p. 29.

to the cavalry, and the third to the artillery and engineers.

But, in 1830, the Bourbon dynasty was again expelled from the throne. Louis Philippe, the son of the famous Duc d'Orleans (Egalité), was proclaimed king of the French; and again the army was re-organized. The policy of the new French king led him to find employment for the army, and the conquest of Algeria soon furnished occasion for its increase, and the employment of his sons in foreign commands. Louis Philippe was ejected in 1848 during a sudden and violent republican movement; and for four years France was a species of democracy, ruled by an assembly with a military president, which, in its turn, in 1852, was succeeded by an empire. The present ruler, the nephew of Napoleon I., was elected emperor by seven millions of votes; and as, from the peculiarity of his personal position, his views of foreign policy, and the commencement of the war with Russia on behalf of Turkey, it became necessary to augment and partially reconstruct the army, it has now been placed upon the following footing:—

The etat-major, or staff, consists of 700 officers, including the marshals, generals, &c., and an "intendance militaire" of 240 persons. Of the general officers there are two grades —generals of division and generals of brigade. There are 90 of the former and 180 of the latter.[1]

The British system of making general officers the nominal colonels of regiments, is utterly unknown in the French army. Every general, without exception, is either an officer or commander of the legion of honour. The corps of the etat-major consists of 25 colonels, 25 lieutenant-colonels, 90 chefs-d'escadron, 140 captains of the first class, 140 captains of the second class, 100 lieutenants. These are attached to the different military divisions, and fill all the regular staff appointments. All aides-de-camp are appointed from this corps. Many of them are employed on the great military survey; and there is either a captain of the second class, or a lieutenant appointed to every regiment, both of cavalry and infantry.

The strength and composition of the French army are at this moment (1856) as follows:—

Imperial Guards.

1 Regiment of Foot Gendarmerie.
2 ... ... Grenadiers.
2 ... ... Voltigeurs.
1 ... ... Zouaves.
1 Battalion ... Chasseurs.
Total, 6 Regiments of 22 Battalions of Infantry.
100 Horse Guards.
1 Squadron of Gendarmerie.
1 Regiment of Cuirassiers.
1 ... Guides.
Total, 14 Squadrons of Cavalry.

7 Companies of Firemen.
9 ... Cavaliers of the Remount.
1 ... Veteran Gendarmes.
5 ... Veteran Subalterns and Fusiliers.
5 ... Veteran Gunners.

The staff of each regiment is the same, viz., 1 colonel, 1 lieutenant-colonel, 2 chefs-d'escadron, 1 major, 1 captain instructor, 2 captains adjutants, 1 major-captain treasurer, 1 sub-lieutenant assistant-treasurer, 1 captain d'habillement, 1 porte-etendard—a sub-lieutenant, 1 lieutenant, or captain of the etat-major, 1 surgeon-major 2d class, 1 surgeon aide-major, 1 veterinary *en premier*, 5 captains commandant, 5 lieutenants *en premier*, 15 sub-lieutenants, 5 captains *en second*, 5 lieutenants *en second*, making altogether 51 officers in every regiment; some of the subalterns, however, of each, are either officers of instruction, or pupils at the great cavalry school at Saumur. The term major is not, as with us, a grade of army rank; it is only used regimentally; the major is a chef-d'escadron in the cavalry, and a chef-de-bataillon in the infantry, and wears the same uniform. The terms used for the non-commissioned officers in the French cavalry differ much from those in use in our service; and it is very difficult to compare the two together—some of their functions being so entirely distinct. The adjutant sous-officier is a squadron sergeant-major; maréchal-des-logis chef is a quarter-master sergeant; maréchaux-des-logis and maréchaux-des-logis-fourriers are sergeants-major; brigadier-fourrier is a sergeant; brigadier is a corporal; the adjutant sous-officier is distinguished by one gold epaulette, if the officers wear silver, and *vice versa;* the other non-commissioned officers have the same distinctive marks as in the infantry.

The *French Artillery*, in its organization, differs considerably from the English; instead of being one corps, it is divided regularly, like the line, into regiments which have nothing whatever to do with each other. These regiments are all exactly on the same footing, the horse artillery not forming a separate regiment but according to the exigencies of the service; a certain number of batteries in each regiment are horse. The artillery divisions of France do not correspond with its military divisions. There are nine altogether; eight in France itself, and the ninth comprising the three provinces of Algeria. Each division is commanded

[1] *Annuaire Militaire de l'Empire Français pour l'Année* 1855.

by a general of brigade, and is again divided into two or three *directions*, at the head of each of which is a colonel. There are a considerable number of officers on the staff, from the number of government works which are under their superintendence, there being not less than 17 establishments for making powder and refining saltpetre, and more than a dozen *arsenals de construction* and *manufactures d'armes;* most of these have foundries attached to them, and are all under the superintendence of the artillery. The *Comité Consulatif de l'Artillerie* is in some respects the French Board of Ordnance. As its name implies, it is more a board of advice than of practical interference, as there is a bureau belonging to the minister of war from which the actual orders emanate; the Comité Consulatif consists of 5 generals of division, and 3 generals of brigade. The establishment of a battery is very similar to that of a company of British artillery—there being a captain-commandant, a captain *en second*, a lieutenant *en premier* and a lieutenant *en second;* the gunners and drivers are not the same as with us, but are quite distinct from each other, there being a certain number of each to every battery according to the nature of its service. A battery may be in three positions, either a horse battery, where all the men are paid alike; a mounted foot battery, where the drivers are paid like the horse battery, but the gunners much less; or a dismounted foot battery, in which, of course, there are no drivers; as in the cavalry the corporals are termed brigadiers, and the sergeants fourriers, which is literally harbingers. The staff of a regiment of artillery consists of: 1 colonel, 1 lieutenant-colonel, 7 chefs-d'escadron, 1 major, 1 riding-master—a captain, 2 adjutants-major—captains, 1 clothing officer—a captain, 1 treasurer—a captain, 1 assistant-treasurer, 1 sub-lieutenant, 1 lieutenant of the etat-major, 1 surgeon-major, 2 assistant-surgeons, 1 veterinary *en premier*, 32 captains, 32 subalterns. A horse battery consists of 4 guns, 8-pounders, and 2 howitzers, 15 centimetres in diameter, which is about ½ of an inch more than the English 24-pound howitzer; each gun and each waggon is drawn by six horses, which, with the two extra waggons and the spare team, make 90 harness horses for each battery. The horses are generally very good, and they pay considerable attention to their being properly matched. The mounted foot batteries consist also of four guns, either 8 or 12 pounders, and two howitzers; the guns and waggons have four horses each. The *pontonniers* (pontoon men) are like our sappers and miners; the men admissible to the corps must understand some trade that is likely to be useful to the service. There is one company generally in Algeria, and the other companies with the headquarters are at Strasbourg in time of peace. The uniform is the same as the artillery, and they are officered indiscriminately with the other regiments. The companies of artillery workmen are employed at the different foundries and arsenals; there are 2 captains and 2 lieutenants of artillery attached to each company, and their uniform is the same; some of these companies are employed in Algeria.

The *Engineers* form a distinct corps altogether, and are not, as with us, merged into the Ordnance; in fact they have no more to do with the artillery than they have with the cavalry and infantry; they have their *Comité Consulatif* of 8 generals, and their separate bureau in the office of the minister of war.

The *Troupes du Génie* are the same nearly as our sappers and miners, and are officered in the same manner by the engineers. The engineer divisions of France are neither the same as the military nor as the artillery divisions. There are 21 districts which are termed *directions*, in France. Each of these is under the superintendence of a colonel, who has from 4 to 14 officers under him, either field-officers or first captains, according to the number of fortified places or towns where there are barracks in the direction. Algeria is divided into three directions, according to its provinces, and has besides an engineer staff; not including the officers commanding the companies of sappers, there are about 36 engineer officers in the colony at present. The engineers are the only army corps who have anything to do with the other French colonies. The *Infanterie de la Marine* perform all the colonial duty apart from Algeria. This they can do very well with a small force, as the colonies are few and comparatively insignificant. Those in which officers of the engineers are stationed are—Guadaloupe and Martinique, in the West Indies; Cayenne, in Guyana, South America; Senegal, Ile de la Reùnion, republicanized from the Ile de Bourbon; Nossibè, and Madagascar; Mayotta, one of the Comora Islands, between Madagascar and the coast of Africa; Oceanie, the Marquesas, and Tahiti. The *Troupes de l'Administration* are divided into two sections—the first is the battalion of government workmen; the second section is called the corps des equipages militaire. This corps bears nearly the same relation to the commissariat that the sappers do to the engineers; the French government not being much in the habit of obtaining their supplies through the medium of contracts, are obliged to keep very large establishments of their own. For instance, the whole of the bread that is supplied to the troops in Paris comes from a government factory, nearly opposite to the Hotel des Invalides. This is all done by the workmen of the first section; the qualification required of every person entering the corps is, to be either a butcher, baker, carpenter, locksmith, joiner, or mason. The 4 squadrons of the second section are employed in conveying provisions and commissariat stores from place to place, and their companies of workmen make and repair all the waggons and carts that are necessary for that purpose. At the same time, although their employment is of a civil nature, they are regular soldiers, have their own officers, and are properly armed and equipped, the workmen as infantry, the squadrons as cavalry; the uniform is gray, with red trousers, shakos like the other troops, and silver epaulettes for the officers. The badge of the corps is a star, which is on their buttons and accoutrements. The regular commissariat corps is very numerous, and is divided into three distinct branches, each comprising a separate body of officers; the ranks, however, are the same in each branch; they are:—

	Corresponding to
Officers d'administration principaux,...........	Commissary-general.
... comptables, 1st Class, ...	Dep.-com.-gen.
... ... 2d Class, ...	Asst.-com.-gen.
Adjutants *en premier*, ...	Dep.-asst.-com.-gen.
... *en second*, ...	Com.-clerk.

The first section consists of 328 officers of different ranks, and is devoted exclusively to the management of the military hospitals, the medical officers only attending to them professionally. The second section has 78 officers in it, and manages the clothing of the army and the issue of tents and all kinds of camp stores. The third section, consisting of 362 officers, manages the preparing and issuing all kinds of provisions for the whole army. The uniform is nearly the same as that of the medical staff; it is a blue coat without epaulettes, red trousers, and a cocked hat.[1]

The French army is at present recruited partly by voluntary enrolment for a term of years, and partly by requisitions; in other words, on nearly the same principle which obtained before the revolution of 1790. The system of requisition is understood to be subsidiary or supplementary to that of voluntary enlistment, but the war with Russia has made it the principal resource. And this applies to other

[1] *Bulletin des Sciences Militaires*, p. 1850–51–52.

nations as well as to France. Modern manners, customs, habits, and pursuits, are primarily adverse to the military service; and this opposition can only be overcome by a conscription of one kind or other. Napoleon laid it down as a principle, "que la conscription est le mode de recrutement le plus juste, le plus doux, le plus avantageux au peuple."[1] But without being prepared to go this length, it may be admitted that it is equal in its operation; that its results are certain; and that the supplies it furnishes are of the best quality: whilst voluntary enlistment is at best a precarious resource, and sends to the ranks little else than the scum and dregs of the people.

The immense French army now afoot receives its impulse, its administrative direction, and its guarantee of preservation, from a staff admirably organized and composed; a corps of control drawn from the ranks of the army, and distinguished by its integrity, intelligence, and firmness; a health corps as solidly constituted by its excellent organization, as by its superior education and courageous devotion; and various administrative departments equally recruited from the army, and which, owing to their actual origin, their military spirit and good service, had acquired full possession of the esteem and confidence of the whole force.

The national character of every people is commonly developed in a very striking manner by its army. "The Frenchman," says Count Bismark, "courageous, impetuous, nay, even terrible in attack, does not possess that cold-blooded, quiet circumspection and endurance which is so indispensable in a defensive war;" and hence he concludes that a war against the French ought to be carried on *offensively*. "A cautious but not the less uninterrupted offensive must be the ruling principle in all projects of operation against the French."[2] Major Beamish delivers a similar opinion. "The French," says this officer, "have, with much judgment, generally endeavoured to become the *attacking* party. They thus not only derived the usual advantage of that system, but adopted the mode of warfare which was peculiarly suited to their national character. The French soldiers are impetuous; but their courage requires excitement, to which *motion* so much contributes. Abstract motion, however, is not sufficient to impel the French soldier into action—he must be first excited by the example of his officer; and were it not for the extreme and universal gallantry displayed by the officers of the French army, few instances of impetuous courage would be recorded on the part of the men. It has been said that 'the French officers will always lead, if the men will follow;' and there have been instances where the former have nobly sacrificed their lives to produce this effect."[3] General Foy, whose endeavours to depreciate the British are at such variance with the better points of his character, says that "to Frenchmen you must always speak," and that "the intoxication of the French is gay, sparkling, and daring; a foretaste to them of the battle and the victory."[4] A still higher authority confirms these opinions. "Le Français, naturellement brave, actif, et impétueux," says Baron Jomini, "fait aisément des conquêtes, mais il les perd avec la même facilité. Dès qu'il cesse de marcher en avant, une sorte de dégoût s'empare de lui; il est difficile de le contenir. Depuis la révolution, surtout, cette disposition s'était accrue de plus en plus: les liens de la discipline ne retenant plus le soldat, il était devenu mutin, raisonneur, et indocile."[5] Colonel Napier's opinion appears substantially to coincide with that of Jomini and other competent judges.[6] In fact, no military nation of Europe has gained so many splendid victories, and sustained so many disgraceful defeats, as the French; whose whole history, indeed, consists of an extraordinary alternation of the most brilliant successes and the most calamitous reverses, of triumphant ascendancy and abject humiliation. "Aucune nation," says Guibert, "n'a perdu de batailles aussi honteuses, aussi décisives, que la nôtre; aucune n'en a gagné si peu de décisives et de complettes."[7]

Latterly their arms have been distinguished by great success. In the war with Russia, arising out of the attempt of the Czar Nicholas in 1853 to advance his troops upon Constantinople in order to obtain, as he expressed it, a "material guarantee" for the good faith of Turkey towards the followers of the Greek religion—the French sent an army of 80,000 men to co-operate with the British in checking the Russian advances by destroying the stronghold of the emperor in the Black Sea. For years stupendous fortifications had been raising at Sevastopol, the principal harbour and arsenal of Russia in the Euxine. It was evident—even if the conversations of the Emperor Nicholas with certain British functionaries had not disclosed his purposes—that he designed the utter subjugation of Turkey. France and England, equally interested in the preservation of the Ottoman Empire as essential to the balance of power in Europe, held it therefore to be of vital consequence that the formidable means of aggression, perpetually presented in the existence of Sevastopol, should be annihilated. The siege of Sevastopol lasted for eight months. It had been prefaced by a fierce but brief contest on the banks of the River Alma. In this engagement, and in two later ones in the Valley of Inkerman and on the banks of the River Tchernaya, as well as in the attacks upon the Russian outworks and the repulse of numerous sorties, the French army displayed all the fine qualities for which it had, in other times, been remarkable. Finally, it crowned its triumphs by assaulting with great vigour and perfect success the formidable Malakhoff Tower, which was the key to the Russian position. In the skill of the engineers, the excellent and rapid practice of the artillery, the accuracy of the riflemen (the *chasseurs à pied*), the dashing bravery of the Zouaves—originally a corps entirely composed of the natives of the French Algerian provinces—and the energy and professional ability of the generals in command, the strongest proofs are given to the world that a French army had not been rendered, by a long peace, inferior to the other armies of Europe. It was a new and interesting sight to behold such ancient foes as England and France fighting side by side in a good cause; and it is due to both armies to state that their intercourse was as cordial, and their emulation as

---

1 Napoleon having established "qu'un million d'âmes fournit chaque année 7000 à 8000 conscrits, et que les besoins de l'administration et des divers états n'en réclamait que moitié," he therefore concluded, "qu'une levée annuelle de 3500 hommes n'offrait, deduction faite des morts, que 30,000 hommes en dix ans," or about a thirty-third part of the entire population. (See Rogniat, *Réponse aux Notes Critiques de Napoleon*. Paris, 1823.) But the draughts on the population of France were never carried to the full extent of the principle, and seldom exceeded 1 in 43 or 44.

See also vol. iii., p. 329, where, in describing the attack of the British position on the crest of the Sierra de Busaco, 27th September 1810, Colonel Napier renders justice to the "astonishing efforts of valour" on the part of the French, and ably discriminates the respective characteristics of the troops engaged on that occasion. The onset of the French was truly terrible, and at one moment had very nearly succeeded.

Army.

noble and generous, as their ancient hostility had been ardent and implacable.

Spanish army.

The Spanish army, which, under Charles V., Pescara, the Duke of Alba, and the Constable of Bourbon, had proved itself so formidable—extending the theatre of its exploits from the Pyrenees to the Po and the Adige on the one hand, and to the Elbe, the Meuse, and the Waal on the other—degenerated rapidly under the disastrous reigns of the last princes of the House of Austria. When Philip V. ascended the throne at the beginning of the last century, it scarcely amounted to 15,000 men. By that prince and his successors, however, it was gradually increased, until, in the year 1792, its establishment amounted to 116,000 infantry, 12,200 cavalry, with upwards of 10,000 artillery, and its effective force to about 120,000 men of all arms. At present it amounts to 99,489 men and 11,395 horses, besides a corps of carabineers for the protection of the frontier. The effective force amounts to 75,000. It is composed of the general active staff, of the staff of the fortresses, of the household troops and royal guard, of the infantry and cavalry of the line, with artillery, engineers, and veterans. Its staff consists of 6 captain-generals, 77 lieutenant-generals, 122 major-generals, 350 brigadier-generals, with inferior officers in proportion. There are 15 captaincies, viz., 12 territorial and 3 colonial. In Spain, and its possessions contiguous to the Peninsula, there are 150 fortresses, posts, forts, citadels, or open towns where troops are in garrison. The household troops consist of six squadrons of the body guard, and a royal corps of halberdiers. The royal guard consists of two divisions of infantry, one division of cavalry, and three companies of artillery, one of which is horse artillery. The first division consists of four regiments of grenadiers, each composed of two battalions, divided into eight companies of 120 men each; and the second of two regiments of the *élite* of the provincial militia, divided into three battalions of four companies each. The cavalry forms a division of two brigades; and the artillery consists of three companies of 100 men, each serving a battery of six pieces mounted. The infantry of the line consists, first, of 10 regiments of three battalions each; secondly, of the Swiss regiment Wimpffen, one battalion only; thirdly, of a regiment, fixed at Ceuta, composed of four companies of 100 men each, the refuse of the army. Seven regiments, of two battalions each, of the same number and composition as those of the line, form the light infantry. The militia consists of 546,286 men, divided into cavalry, infantry, and artillery. The cavalry consists of 13 regiments, of which 5 are of the line, and 8 light horse, each of four squadrons, composed like those of the royal guard; together with two companies of cuirassiers at Ceuta, one formed of native Spaniards, and the other of Moors. The royal corps of artillery is divided into the theoretical and practical. The troops of this arm consist, first, of 6 battalions of foot artillery, in garrison at Barcelona, Carthagena, Seville, Coruña, and Valladolid; secondly, of 4 companies of horse-artillery, in garrison at Carthagena and Seville; thirdly, of 5 companies of artificers; fourthly, of 5 battalions of the train; fifthly, of 3 brigades and 15 companies fixed in garrison, but exclusive of the *personnel* in Cuba and Porto Rico. This arm has a splendid museum at Madrid, besides a theoretical and practical school, directed by a brigadier-general or colonel, in the principal town or place of each province. The engineers are a corps of officers not regimented or brigaded, consisting of an inspector-general, 14 directors, sub-inspectors, 17 colonels, 20 lieutenant-colonels, 34 captains, and 56 lieutenants; together with a regiment of sappers, consisting of 2 battalions of 8 companies each, viz., 5 of sappers, 1 of miners, 1 of pontonniers, and 1 of workmen. The establishments of this arm are, a topographical depôt-general, or collection of maps, plans, and military memoirs; a museum containing representations in relief of the fortresses, and different models of fortification; and an academy for the instruction of young officers intending to enter this branch of the service, after they have passed through the primary school of Segovia. All these establishments are situated in the capital. A body of 10,499 men compose the gendarmeries, and there is a company of militia in the Canaries.

The Spanish army is recruited by voluntary enrolment, and, in case of insufficiency, by ballot or conscription. The term of service is eight years for the first enrolment or ballot, and two or four for the second, when the soldier becomes entitled to an increase of pay. Before the war of independence no one could attain the rank of officer without having been a cadet; and each cadet was bound to prove his nobility. But after the return of Ferdinand these proofs were dispensed with, and sergeants now obtain a third of the sub-lieutenancies—the other two-thirds being reserved for the pupils of the military school of Segovia, who have passed the customary examinations at the end of their course of study. The dress and equipment of the Spanish army are in the worst state; the pay of the troops is exceedingly irregular; and their discipline is, in consequence, as bad as it is possible to imagine, or rather, there is scarcely such a thing known.[1] "L'Espagnol, sobre, vigoureux, infatigable," says Jomini, "possède de grandes vertus guerrières, mais il manque d'activité soutenue. Si dans ces dernières révolutions, son caractère se soumit difficilement à la discipline, nous avons été induit à penser, en observant l'esprit du peuple, que dans les temps ordinaires, il y serait plus facilement ployé. Son courage tumultueux prêtait beaucoup à une prompte désorganisation, car la déroute est toujours compagne de cette disposition naturelle des esprits chez les peuples méridionaux."[2]

During the war in the Peninsula in 1809–14, Wellington experienced a great deal of trouble from the impossibility of relying upon the steadiness of the Spanish troops, and the good spirit of their leaders. At the battle of Talavera the British leader found it necessary to place his 34,000 Spanish allies where their firmness would be exposed to the slightest test; but even this precaution was unavailing. Five thousand Spaniards decamped immediately after the order of battle had been formed! Yet their generals claimed for them the honour of the victory—the chief of them being a senile dotard, who had stipulated for all the consequence of command without the responsibility. Since that time there has been little or no evidence of an improvement either in the composition of the troops or the character of their leaders. In a word, the Spaniards afford a striking illustration of the truth of Napoleon's maxim, that *in war the moral is to the physical force as three parts to one.*

Portuguese army.

After the general peace of 1814, when all the powers of Europe had reduced their military establishment, Portugal alone did not follow their example, but fixed the peace establishment of its permanent army at 49,268 infantry and 5230 cavalry; which, with the militia, made a force of 59,325 men, or about 22 soldiers for every 100 inhabitants. Such a state of things, however, was much too violent to be durable. Accordingly, one of the first cares of the constitutional go-

[1] *Notice sur l'Armée Espagnole,* redigée sur *El Estado Militar* de 1828 et sur un manuscrit. Paris, 1829. *Bulletin des Sciences Militaires,* tom. v., p. 420. With regard to the present state of discipline, or rather of indiscipline, of the Spanish army, the author of the *Notice* observes, "La discipline n'a jamais subsisté dans l'armée Espagnole. Ce n'est pas qu'il manque de réglement; il en existe un fort étendu, redigé avec soin d'après le nôtre (le Français) de 1792; mais c'est un frein qu'on n'a pu jusqu'ici amener l'Espagnol à supporter. Au respect près que le soldat a pour son officier, il n'y a pas l'ombre de discipline."

[2] *Histoire Critique et Militaire des Guerres de la Révolution,* tom. i., p. 242.

Army.

vernment of 1821 was to reform a military system so disproportionate to the population and the financial resources of the kingdom. The armed force since that period has therefore consisted exclusively of the permanent army and the militia. The permanent army is composed of a general staff, an engineer corps, 18 infantry regiments of the line of 9 companies each, 9 battalions of *chasseurs-à-pied* and 6 regiments of *chasseurs-à-cheval*, 3 regiments of artillery, a battalion of engineer artificers, a company of soldiers of the train, a municipal guard, and 30 companies of veterans. The general staff consists of 1 marshal-general, 2 marshals of the army, 10 lieutenant-generals, 16 major-generals, 15 brigadier-generals, 6 superior officers, 6 subalterns, 12 aides-de-camp, 12 secretaries, 10 employés, and a surgeon-in-chief. The engineer corps (*corpo de engenheiros*) is composed of 4 colonels, 4 lieutenant-colonels, 8 majors, 12 captains, 12 lieutenants of the first class, and 12 of the second; in all 64. Each regiment of infantry of the line and of light troops consist of 44 officers and 780 non-commissioned officers and soldiers. The effective strength of a regiment of artillery is 551 men, including 45 officers. The corps of the train of artillery (*artilheros conductores*), reduced to a single company by the organization of 1821, is composed of 12 officers, 30 soldiers, and 70 mules (*bestas muares*). The battalion of engineer artificers consists of 263 men, including 65 officers. Each of the 30 companies of veterans is from 70 to 80 strong, including 2 officers. The municipal guard of Lisbon consists of 1766 men, including officers; together with a battalion of *gens d'armerie à cheval* 238 strong, divided into 4 companies. The effective force of the permanent army on the peace establishment is therefore about 26,000 foot and 2000 horse—18,000 foot are in active service, 4600 in Africa, and 4400 in the Portuguese settlements in Asia. But there is a local force in the islands and colonies amounting to 28,000 men.[1] The *ordinenzas*, which formed 441 legions or *capitanea mores*, were abolished by the Cortez in 1822, to the great satisfaction of the nation, which justly regarded this institution as a most grievous scourge. They were a sort of levy *en masse*, which all individuals between the age of 16 and 60, unless serving in the regular army or in the militia, might be called upon to join at the shortest notice. The army, which is indebted for its organization to Marshal Beresford, is well disciplined and instructed. Its equipment and arms are the same with those of the English troops.[2]

Austrian army.

At the period when the Emperor of Germany engaged in war with revolutionary France, the Austrian army was on a very effective footing, both in regard to organization and numbers. The infantry, it is true, though well trained and disciplined, wanted vivacity, and its physical was superior to its moral force. But the cavalry, which was composed of admirable materials, rivalled the Prussian squadrons in instruction, and surpassed them in other particulars. The artillery and engineers were also good, although the *matériel*, less perfect than that of the French, was either too heavy for pieces in position, or too light for efficient service in the field. Nor was the staff deficient either in erudition or in talents; but its theories were antiquated and vague, resting partly upon the system of cordons attributed to Lascy, and partly also upon certain hypotheses, which it was gravely proposed to put to the test of experiment in the field. At the commencement of the war with France, the imperial army consisted of 232 battalions of infantry and 220 squadrons of cavalry; and as the battalions were very strong, being raised by means of reserves to 1200 men and upwards each, the whole of the Austrian force at this period may be estimated at 240,000 foot, 35,000 horse, and 10,000 artillery.[3] But the reverses it experienced in consequence of an obstinate adherence to a vicious system, and the exigencies of the long and protracted struggle with republican and imperial France, led to successive augmentations of the effective force, until at one time it considerably exceeded 700,000 men of all arms. At the general peace of 1814, however, Austria, exhausted by a war of five-and-twenty years, reduced her military establishments nearly one-half; adjusting the scale of peace so as to render it commensurate with that which, it was conceived, France would adopt as soon as the Bourbons felt themselves in a condition to re-organize a permanent force. Several changes have since been made, the most important of which have taken place in the past eight years, arising out of the disturbed state of the eastern part of the continent of Europe; but the account which follows, derived from the most authentic sources,[4] will be found to exhibit a correct view of the actual force and organization of the Austrian army, consisting of the troops of the line, and the *militär-gränzen*, or *military of the frontiers*.

The *infantry*, exclusive of the 14 regiments of the frontiers, is composed of 62 regiments of the line, 1 regiment of chasseurs; besides, in time of war, the infantry of the staff and the landwehr. Of these, 3 are recruited in Lower and 2 in Upper Austria, 5 in the interior and in the Illyrian provinces, 9 in Bohemia, 5 in Moravia, 11 in Galizia, 4 in the Venetian States, 4 in Lombardy, 12 in Hungary, and 3 in Transylvania. The different regiments are designated respectively by the names of their provinces, and those of the officers who are proprietors therein (*inhaber*). A regiment of the line consists, in time of peace, of 1 colonel, 1 lieutenant-colonel, 3 majors, 21 captains, 73 subalterns—in all 99 officers, not including 5 staff-officers, 2 grenadier and 16 light infantry companies, containing 3318 men. The companies of grenadiers form separate battalions, commonly consisting of three divisions or six companies. The Hungarian and Transylvanian regiments consist, in time of war, of 4 battalions of 6 companies each; and the company contains 200 men. The force of the infantry of the line amounts, therefore, on the peace establishment, to 1984 companies, or 372 battalions, making a total of 425,878 men during war. By the *military frontiers* are understood the provinces and districts conterminous with Turkey, to the east and south of the empire; which, by reason of the military service, internal as well as external, that their male population is subject to, have an organization entirely military, some districts of Transylvania alone excepted. These military provinces furnish 14 regiments of national infantry, a battalion of *tschaikists* or watermen of the Danube, and a regiment of hussars (*szekler*), who, inasmuch as they are liable to be called to join the army, really form part of it, but who, in respect of their particular organization, may be considered, in time of peace, as constituting a distinct force. Military Croatia comprehends six districts, each of them furnishing a regiment, which bears the name of the chief place of the district, and consists of 12 companies. The service of these regiments in time of peace is confined to guarding the cordon. Similar service is rendered by the regiment of gens-d'armes in Lombardy, and the military cordon in Galizia. The light infantry is composed of the

Army.

3 Jomini, *Guerres de la Révolution*, tom. i., p. 232.

4 The account of the Austrian army, given in the text, is derived partly from the *Allgemeine Militär-Zeitung*, which appeared at Leipzig and at Darmstadt in 1826, partly from the *Constitution de l'Armée Austrichienne* of Bergmayr, partly from the *Annuaire Militaire Austrichien*, and partly from Mr Edward Thompson's "Austria," published in 1849, together with a variety of papers in the *Bulletin des Sciences Militaires*, and the *Almanach de Gotha* of 1856.

imperial regiment of Tyrolese riflemen, consisting of 4 battalions of 4 companies each; 12 battalions of chasseurs, 4 companies each in time of peace, and 6, with a depôt company, in time of war; 17 national frontier infantry regiments, and 1 Illyrian Banatisch battalion. A company of chasseurs consists of 195 men, including officers. The garrison battalions, composed of a sort of demi-invalids, unfit for the service of the line, are stationed, 1 in Buckowina, 1 in Esclavonia, 1 in Hungary, 1 in Dalmatia, and 1 in Lombardy, and consist each of six companies, with the same complement of officers and non-commissioned officers as the companies of the line. The divisions of infantry of the staff (*stabs-infanterie-division*), are composed in the same manner; and organized, in time of war, for the purpose of guarding the headquarters and the magazines of the army, and of removing the wounded from the field of battle to the nearest hospitals. The number of battalions of the landwehr is seventy. In each district of country (Hungary, Transylvania, and Italy excepted) assigned for the recruitment of a regiment, two battalions of landwehr are raised and attached to such regiment; the one containing the men who are the least necessary to their families, and the most proper for the service, and the other, the surplus of those who are obliged to form part of the landwehr. The first battalion is exercised fifteen days in the year, the second only eight hours. The commandants receive their orders from the colonel of the regiment of the line to which their battalions are respectively attached. The landwehr is principally destined for the service of the interior; but it may also be sent to an active army. In either case it is paid the same as the troops of the line.

The *cavalry* consists of 8 regiments of cuirassiers, 8 of dragoons, 12 of hussars (exclusive of the frontier regiment), and 12 of hulans; together with, in time of war, the dragoons of the staff (*stabs-dragonner*); all raised, like the infantry, in different provinces, viz., 3 regiments of cuirassiers in Bohemia; 3 in Moravia, 1 in Lower Austria, and 1 in Central Austria; 3 regiments of dragoons in Moravia, 1 in Upper and Lower Austria, and 1 in Lower and Central Austria; 1 regiment of light horse in Moravia, 4 in Bohemia, 1 in Galizia, and 1 in Italy. The hussars of the 12 regiments are all either Hungarians or Transylvanians. The regiments of hulans consist of inhabitants of Galizia and volunteers. In time of peace, the regiments of cuirassiers and dragoons consist of 6 squadrons, and the other regiments of 8; making in all 260 squadrons. Two squadrons make a division; and in regiments which have 8 squadrons or 4 divisions, 2 are commanded by the majors. The dragoons of the staff, of which there are several divisions in time of war, have the same destination as the infantry attached to it, and are besides employed in repressing disorders committed by marauders, and in other like services.[1]

The *artillery* is divided into three parts, or distinct corps, viz., the field artillery (*feld artillerie*); the artillery of the arsenals and magazines (*feld zeugamt*); and garrison artillery (*garnison artillerie*). The *field artillery* consists of 168 batteries, or 3898 men and officers. It is recruited by corporals of artillery, and performs the most difficult as well as important service to the army. A regiment of field artillery is composed of a staff and 4 battalions, one of 6 companies, and three others of 4 companies each; making in all 18 companies. A company serves three or four batteries of 6 pieces; and each battery is commanded by a lieutenant or major-firemaster. The train of the army furnishes the horsing of the batteries, which is under the command of officers of that corps, and generally independent of the chiefs of batteries, but subordinate to them in this particular service. The rocket corps is established at Neustadt, near Vienna, where it has for some years been occupied in fabricating Congreve rockets, we believe with considerable success. The *artillery of the arsenals and magazines*, consisting of a staff and *personnel* of the necessary workmen, furnishes the field artillery, and the equipages of war, with the requisite arms and munitions, and it guards them when in magazine. The *garrison artillery*, charged with the service in fortresses, is divided into fourteen districts, determined by the provinces, and proportioned in numbers to these districts. Its total strength is 7400 men and officers. The district of garrison artillery of Vienna comprehends an arsenal, containing all the equipage of sieges; and attached to it are a foundry, an establishment for boring cannon, and manufactories of saltpetre and gunpowder.

The *engineer department* comprehends a corps of engineers, with the sappers and miners. The pontoon train is attached to the staff, and is under the direction of an *oberstschiffamt* or chief of boats. The train of corps of military equipages (*militär-fuhrwesens-corps*) is wholly independent. The engineer corps is composed of 4 generals, 6 colonels, 9 lieutenant-colonels, 18 majors, 42 captains, 30 captains *en second*, 30 lieutenants, 30 sub-lieutenants, 12 cadets, and 5000 men. Each command of military division embraces a district of fortification; consequently there are fourteen such districts, to each of which is attached a director, who is taken from the generals or officers of the engineer staff. In each place there is also an engineer-in-chief, who is an officer of the staff or a captain of engineers; but in Vienna, Milan, Peterwaradin, and Venice, the director performs the functions of chief engineer. The corps of miners is composed of a staff, five companies, and a garrison detachment; and the corps of sappers, of a staff like that of the miners, six companies, and a garrison detachment. The pontoon corps consists of a staff and 2 battalions of 4 companies each. In time of war the number of battalions is three, two of which have 6 companies and one 4; besides a company in depôt. The train or corps of military equipages consists, in time of peace, of 12 divisions of transport (*transports-division*), and 20 sets of horses for field batteries (*exercier-batterie-bespannung*). Each division is provided with 90 horses; and all the detachments of the corps stationed in a province are under the orders of a commandant. In time of war the military equipage train consists of seven principal divisions, viz.,—1. the artillery transport division; 2. that of pontoons; 3. that of flying bridges; 4. that of baking; 5. that of health for the transport of the wounded; 6. that of victualling; and, 7. that of general transport.

Two regiments of the same or different arms form a brigade, which is under the orders of a major-general; and two or three brigades form a division, which is commanded by a field-marshal-lieutenant. In time of war, corps-d'armée are organized, each consisting of several divisions, and under the orders of a general of cavalry or artillery, or of the oldest field-marshal-lieutenant. In the Austrian army there are at present 6 field-marshals, 23 generals of cavalry and ar-

[1] Jomini has particularly remarked the superior composition, organization, and discipline of the Austrian cavalry, which has proved its excellence in many bloody encounters, and, when led with talent, has never failed to distinguish itself. At the battle of Würtzburg, 3d September 1796, Wartensleben passed the Maine with twenty-four squadrons of cuirassiers, attacked the French cavalry under Bonneau, overthrew it, and thus decided the victory. "This brave veteran," says the Archduke Charles, "impressed with the importance of the order which he had received, dashed into the Maine at the head of his cavalry, and swam across." "This manœuvre," he adds, "was completely successful: the French cavalry, which had awaited the charge without stirring, was overthrown." At the battle of Leipzig, the Austrian cuirassiers, commanded by Nostitz, "covered themselves with glory." On the 16th October, at one o'clock in the afternoon, Nostitz, having scarcely passed the Pleisse at Gröbern, attacked the lancers and dragoons of the French imperial guard, overthrew them, and then broke several squares of infantry. Other instances of a similar kind might be mentioned.

tillery, 116 field-marshal-lieutenants, and 164 major-generals, in actual service; 9 generals of cavalry and artillery, 30 field-marshal-lieutenants, and 92 major-generals, unemployed. The guards form no part of the army. They are divided into the German guard, the noble Italian guard, the gardes du corps, and the gendarmerie of the guard. The military institutions of the first order consist of the company of cadets at Olmütz, that of Gratz, the military academy for cadets at Vienna, the five regimental schools of artillery, the school of bombardiers, and the academy of engineers. The total of the peace establishment of this army is 315,000 infantry and 50,000 cavalry, with a reserve of 250,000; while its war establishment amounts to 521,000 infantry, 131,000 cavalry, and 60,000 artillery.

Prussian army.

At the death of Frederick the Great, the army of the Prussian monarchy, amounting to about 200,000 combatants, was accounted the best in Europe. Proud of a struggle without example in modern annals, and of the superiority of the genius of their king, the victors of Leuthen, Rosbach, and Torgau added to this force of opinion an instruction in great manœuvres, which the troops of no other nation approached, much less rivalled.[1] The successor of Frederick, to whom this superb army descended, though possessed neither of his genius nor his ambition, was at great pains to maintain the reputation which it had acquired; and some laurels that had been easily gathered in the Low Countries seem to have inspired him with the notion that it was still capable of equalling, perhaps surpassing, the brilliant achievements which had established its renown. In this spirit, and, doubtless, believing that the French nation might be reduced with the same facility as the insurrection in Holland, the Prussian monarch put himself at the head of the confederacy formed to crush a people who had risen in arms to assert their liberties and preserve the integrity of their territory. But the issue proved how much he was at fault in his calculation. For a mercenary and mechanical army, however perfect its discipline and instruction may be, can never triumph over a generous people, inspired by patriotism, endowed with high military qualities, and resolved to conquer or to die in defence of their liberties. Besides, the Prussian army of this period[2] was not a national one, nor was it animated by a common feeling. The half of it, as at Frederick's death, was still composed of deserters from all nations, or volunteers enlisted in every circle of the empire;[3] it was neither inspired by the genius of its chief, nor excited by any feeling calculated to improve its moral force; discipline formed the only tie by which it was held together. Nor was it long ere its inferiority was proved; and its pride severely humbled. The affair of Valmy opened the king's eyes; and henceforth, more docile to the suggestions of prudence, he negotiated for permission to withdraw to the right bank of the Rhine the wrecks of that army, the glory of which had just been eclipsed in the plains of Champagne by battalions of youthful volunteers. He had been taught a lesson, by which he did not fail to profit; and after the unsuccessful campaigns on the Rhine, he crept ingloriously out of the contest which he had been so eager to commence; leaving the empire and Austria to the undivided resentment of the conquerors. But he re-established his army, while his late ally was maintaining a death-struggle. The parades and manœuvres of Potzdam were resumed with their wonted éclat; confidence revived; and Frederick began to flatter himself that he alone could re-adjust the disturbed equilibrium of Europe. He failed, however, to observe the prodigious development which the military art had received in the course of the revolutionary war, or at least he neglected to profit by the discoveries to which it had given birth; and, as he had formerly deserted his ally at the beginning of the contest, so now he took the field just at the moment when that same ally was being overthrown at Austerlitz, and compelled to accept the terms dictated by the conqueror. And at Jena as at Auerstadt, at Halle as at Lubec, he paid the price of his procrastinating folly. But misfortune, a rough schoolmistress, had inculcated some useful lessons. The military constitution of Prussia was changed; foreign recruitment ceased; a national army was formed; the privileges of the nobles were abridged; old institutions were reformed; discipline was improved by being simplified; the arming and equipment of the army were improved in all their branches; the best parts of the French military system were adopted; the patriotism of the nation was roused; in short, during five years, Prussia was silently but actively employed in preparing those elements of strength which, in 1812, delivered the monarchy from the yoke of the stranger, and re-established her at the head of the second-rate powers of Europe.

The armed force of the Prussian monarchy is composed, first, of a permanent army; secondly, of a war reserve, or *landwehr*, in two bans; thirdly, of a *landsturm*, or sedentary national guard. The permanent army is composed of young men of family who are destined to the profession of arms, and are named officers after undergoing certain examinations; of volunteers, who clothe, equip, and support themselves for a year at their own charge; of persons between the ages of 17 and 40, who enlist voluntarily, and receive regular pay; of a part of the youth from 20 to 25 years of age, raised by means of requisition; and, lastly, of veterans or soldiers who consent to remain in the service beyond the term prescribed by the law. The regular *infantry* consists of 63 regiments of 144 battalions; the *cavalry* of 38 regiments of 4 squadrons each, 10 of which are cuirassiers, 5 dragoons, 13 hussars, and 10 hulans—in all 158 squadrons;[4] the *artillery* of 24 brigades, each consisting of 2 batteries, 8 field pieces; and the *gens-d'armerie*, of 8 brigades, divided each into 2 detachments.[5] All the youth who have not served five years in the active army or in the reserve, form part of the *first* ban of the *landwehr*, until they attain the age of 30 years complete. The *second* embraces those from 32 to 40 years of age; and both classes, during time of peace, remain at home, pursuing their ordinary avocations. But, in the event of war, the first ban is destined to reinforce the permanent army; and the second to form the garrisons of strong places, and even, in case of need, to send detachments to the army in the field. The *landwehr*,

[1] *Guerres de la Révolution*, tom. i., p. 228. Notice sur le Système Militaire de la Prusse, *Bullet. des Scien. Milit.*, tom. iii., p. 417, 461, 541, et tom. v., p. 417. See also *Archiv für neuere Kriegs und Armée Geschichte*, vol. i., part 1st; and *Zeitschr. für Kunst, Wissenchaft, und Geschichte des Krieges*, part 2d, 1817.

[2] At the commencement of the French Revolution the Prussian army consisted of about 120,000 infantry, 35,000 cavalry, and from 7000 to 8000 artillery, with a most respectable corps of engineers. (*Guerres de la Révolution*, i. 232.) In 1806, it amounted to 260,000 men of all arms. (*Etat Comparatif de l'Armée Prussienne en* 1806 *et en* 1827. *Bullet. des Scien. Milit.*, tom. v., p. 417.)

[3] Jomini reckons the number of foreigners serving in the Prussian army at this period at only *a third part* of its entire strength; but we agree with the author of the *Notice sur le Système Militaire de la Prusse* in thinking it amounted to a half. The data on which this conclusion is founded appear amply to warrant the statement made in the text. (*Hist. Crit. et Milit.* i. 233.)

[4] The Prussian cavalry, in the time of Frederick, was confessedly the best in Europe. "L'infanterie Prussienne," says Jomini, "quoique manœuvrière était cependant loin d'atteindre le degré de perfection auquel Seidlitz avait porté le cavalerie: cette dernière arme tenait alors le premier rang en Europe." (*Hist. Crit. et Milit.* i. 231. See also *Cavalry Lectures*, p. 329.)

[5] The gens-d'armerie is of three kinds: the *armée gens-d'armerie*, divided into detachments stationed at the headquarters of generals of corps-d'armée; the *land gens-d'armerie*, consisting of 80 wachtmeister and 1240 gens-d'armes, of whom 1080 are mounted; and the *granz-gens-d'armerie*, which assists the employés of the customs in discharging their duties on the frontiers.

Army. like the permanent army, is composed of infantry, cavalry, and artillery. In the year 1827 the infantry of the first ban consisted of 116 battalions, and the cavalry of 104 squadrons. Hence, if we include 54 garrison companies, and 18 of invalids at Berlin, Stolpen, and Rybnik, the total of the peace establishment of the Prussian army will amount to 122,000 men, while that of war would not be less than 250,000 men of all arms; and such is the admirable military organization of the country, that two months only are necessary to raise the army to the full complement of the war establishment. In Prussia the cavalry is a preponderating arm. Of the 122,000 men composing the peace establishment, 37,000 belong to this branch of the service. The *landsturm* is a levy *en masse* of men from the age of 17 to that of 50; and in cases of imminent danger it is called out by a royal ordonnance. It is formed into urban and rural companies, and, like the French national guard, performs, if necessary, the duties of the interior; thus leaving the whole of the permanent army and the *landwehr* available for the service of the field. The actual constitution of the Prussian army is strictly economical in all its parts, and the number of military functionaries is reduced to the lowest possible scale consistent with the efficiency of the service. In Prussia every man who wears a uniform works hard for his money.

All Prussians, from the age of 20 to 50, are held liable to military service, but they only serve regularly from 20 to 26. The duration of service is consequently fixed at five years; but, in time of peace, the requisitionary youth remain only the first three years under their colours, after which they return to their homes, and are not called out again, except for a few weeks towards the expiry of the fifth year, when they are inscribed in the *landwehr* of the first ban. The population of Prussia being 11,500,000 souls, about 98,000 males will annually attain the twentieth year of their age. Hence, if we deduct 38,000 for such as are excepted from military service on account of their age or their status in society, the total number of disposable persons, between the age of 20 and 25, will amount to 395,000. And if to this we add that portion of the male population from 25 to 32 years of age who are eventually called to the service, it will follow that Prussia, without having recourse to the second ban of the *landwehr*, could raise 900,000 men trained to the use of arms; while France, even since 1824, when the re-organization of her army commenced, could scarcely bring into the field more than 480,000 men, of which the one-half would be nearly uninstructed in the use of arms. The annual renewal of this army by thirds renders it necessary to push, with the utmost activity, the instruction of both infantry and cavalry, and to pay little regard to that martinet precision which formerly characterized the Prussian tactics, but which is of so small use in the presence of an enemy. The showy on parade has consequently been sacrificed to the useful in the field; and the mere foppery of war has given place to movements and evolutions, which are recommended alike by their simplicity, and by the testimony which experience (the best of all instructors) has borne in their favour. So long ago as the year 1808, the degrading discipline, introduced by the father of Frederick the Great, was abolished by the *kriegs-artikel* or the martial law; and military punishments are now principally confined to hard drills, confinement of various degrees, retrogradation in rank, and some others of a still milder description. Finally, the first grades are the reward of merit established by examination, and as such open to all; while, from the rank of sub-lieutenant to that of general, and even beyond it, seniority (that conservative law of acquired rights) regulates the advancement of officers, and ultimately insures the veteran his reward. Thus, after sustaining the greatest disasters, the Prussian army has survived its dispersion in 1807, and risen, as it were out of its ashes, stronger and better constituted than at the period when it was so rashly opposed to the undivided power of France, wielded by the master-hand of the greatest warrior of modern times. "Heureux les gouvernemens," says a French military writer, "auxquels les malheurs servent de leçons!" Nor would their "happiness" have been much diminished had such governments remembered in victory the promises made to the people in misfortune, and shown but half as much zeal to improve *their* condition as to rectify the defects of their military systems.

Russian army. At the period of the Emperor Alexander's death, the distribution of the Russian and Polish forces was that of an army ranged in order of battle, with its front facing the west. 1. The advanced guard of this army was formed by the Polish army and the corps d'armée of Lithuania; presenting a mass of 80,000 combatants, under the command of the Grand Duke Constantine. In point of mechanical instruction, no army in Europe could be compared to it. Disposed in cantonments of about 150 leagues in length, from Lowicz to Minsk, and 146 in breadth, between Kowno and Dubno, it could be concentrated, at Warsaw or at Brzecs-Littowsky, in less than three weeks. 2. The army of the right was composed of the corps d'armée cantoned in Courland and Livonia, of the corps of the guard, and of the first corps of the cavalry of reserve; which, united, formed also a mass of 80,000 combatants. These were perhaps the only troops which, in point of mechanical perfection, rivalled the army of the advanced guard under Constantine. Their cantonments extended from Polangen to Pleskof, about 132 leagues, and from Revel to Wilkomirsz; and eighteen days at the most were sufficient for assembling them on the Niemen. 3. The army of the left, denominated the second army, was equally formed of a mass of 80,000 combatants, cantoned in the Chersonesian governments. The greatest depth of its quarters, from Choczym on the Pruth to Czerkasy on the Dnieper, was about 106 leagues; and the greatest breadth 180 leagues, between Machnowka, near the southern frontier of Volhynia and Simpherapol in the Crimea. Three weeks were necessary for concentrating it on the Pruth. 4. The army of the centre, called also the first or grand army, forming a mass equal to the three preceding armies, and consequently consisted of 240,000 combatants. Its cantonments extended on one side to more than 234 leagues, or from Kaszin, on the frontier of the government of Tver and of Jaroslaf, as far as Saratow; and, on the other, to upwards of 320 leagues, from Ostrog to Moroum, on the frontier of the government of Vladimir and of Nijnei-Novgorod. It required six weeks at least for concentrating itself in the province of Volhynia. 5. Besides these four armies, consisting of 480,000 men, Russia had also several corps, of various descriptions, amounting to more than 267,000 men; viz., the corps of Finland, of Orenburg, and of Siberia, 45,000 strong; the corps of the Caucasus, 85,000; the military colonies, 67,000; and the troops in garrison, 70,000; thus making a grand total of 747,000 men, exclusive of the Kirgishes, Baschkirs, and other Tartar hordes, of whom from 250,000 to 300,000 may in case of exigency be brought into the field. The whole military force of the Russian empire, at this period, may, therefore, be estimated at above a million of men, or a forty-ninth part of the entire population; while the country, as we have just seen, was organized into one vast camp, arranged upon strategic principles, so as to render the transition from a state of peace to a state of war easy and expeditious, and, with formidable means of aggression, to combine defensive resources of almost incalculable extent.[1]

The contest with Turkey in 1828 and 1829, and Poland

[1] *Etat des Armées Russes et Polonnaises à l'époque de la mort de l'Empereur Alexandre, ou comparaison entre ces deux armées et les autres puissances armées de l'Europe.* Paris, 1826. Mauvillon, *Militär Blätter* for 1826, part 1st. *Bulletin des Scien. Milit.*, tom. iii., p. 385.

in 1830, produced no sensible derangement of this system, and only altered for a time the relative proportions in the numbers of the four principal armies, according as troops were moved upon the various strategic points in the theatre of war. But the *lacunæ* created by the casualties of campaigns in Moldavia, Bulgaria, Rumelia, and Circassia were soon filled up; and, consequently, the above account of the military organization and force of the Russian empire was as applicable in 1853 as it was from the death of Alexander in 1826 to the commencement of the Turkish war in 1828. The Russian army, at different periods of the campaign of 1828, never had more than 88,000 men in its first line;[1] a force which was not calculated, certainly, to excite any very great degree of alarm in the minds of other nations. M. Tolstoy, it is true, alleged that political reasons prevented the employment of a greater force; and that if the Russians only brought forward 88,000 men in the first campaign, "c'était qu'ils ne voulaient point effrayer l'Europe et réveiller des jalousies qui sommeillaient." But closer observers saw reason to believe that the real cause why the campaign was undertaken with a force comparatively so small, did not consist in any particular respect for the "slumbering jealousies" of other nations, but in the supposed inability of Russia to take the field with a larger army; that her physical means are out of all proportion greater than her financial resources or power of developing them in a foreign war; and that however formidable or invincible she might prove to an enemy invading her own territory, a long period must yet elapse before she could be in a condition to occasion any serious uneasiness to the nations of the south and west of Europe. Even in the campaign of 1829, when so many losses were to be repaired, and the reputation of the Russian arms, if possible, to be freed from the tarnish they had contracted in the course of the preceding one, Count Diebitsch was compelled to attempt the passage of the Balkan with no more than 30,000 men; and, in point of fact, he appears to have arrived at Adrianople in the month of October with less than the third of that small force; a miracle of fortune, certainly, but, at the same time, a conclusive proof of the exhausted state of the Russian finances, and of the inability of the Czar to carry on a distant and protracted war. Diebitsch owed his success to two causes—the powerful cooperation of the fleet, and the despairing fatalism, or rather infatuation, of the Turks. But the fortunate result of the enterprise did not blind the world as to the circumstances under which it was undertaken, nor conceal the weakness which preternatural folly, on the part of the Osmanlis, at length gilded with victory.

Nevertheless, in 1853 (a lapse of 24 years), the Emperor Nicholas, after a series of aggressions which extended the Russian dominion S. of the Caucasus into Georgia and Mingrelia, came to the conclusion that the Ottoman Empire was reduced—by misgovernment, internal intrigues, and the hostility engendered among the orthodox Mussulmans, by the reform of the Sultan Medjedi—to a state of feebleness compared to that of "a sick man;" and that, therefore, it would fall an easy prey to Russia. Accordingly, upon the breaking out of a quarrel between the Greek and Latin Christians in the Holy Land, and the determination of the Porte to act with impartiality in the dispute, the Emperor of Russia, as has already been stated when treating of the French army, stepped in, and, assuming the character of the head and protecter of the Greek Church, claimed preferences for the Greeks. These the Porte refused to recognise. Hereupon the Czar marched an army across the Pruth towards the Danube. The Turks flew to arms, and gallantly opposed the Russian armies, defeating them at Oltenitza, Giurgevo, and Kalafat, and compelled them to raise the siege of Silistria. But it was evident that, single-handed, Turkey could not stand long against Russia. The fate of Constantinople, and, consequently, of the balance of power in Europe, raised general apprehension. It became evident that to prevent the Mediterranean from becoming, like the Black Sea, a Russian lake, a formidable alliance of the Western Powers was indispensable. France and England, estranged for centuries, accordingly became fast friends. Sardinia joined them; and each contributing a quota of ships and troops, the fleets and armies of the combined powers attacked Russia in the Baltic and the Black Sea, destroying some of her strongholds, and compelling the annihilation of the men-of-war which floated in the harbour of Sevastopol, and the fortified town and arsenal of Sevastopol itself. Even while we write the war continues; and Russia having put forth all her energies to continue the defence of her possessions, viz., the Crimea and the Baltic, her military force now stands at the present rate:—

The Great Mobile (or *Moveable*) *European Army*.—The imperial guard—12 regiments of infantry, of 3 battalions each, containing 1000 men; 7000 life-guards—making a total of 40,000 infantry, 3840 light cavalry, and 120 guns stationed at Warsaw.

The Grenadier Corps, containing 12 regiments, of 4 battalions each, or 48,000 men; 1000 sappers, 1 brigade of hussars, and 1 brigade of hulans, making 5120 men; 1 division of foot artillery with 120 guns, and a brigade of horse artillery with 16 guns, stationed at Novgorod.

The Infantry Corps.—288 battalions, of 1000 men each; 6 battalions of sappers, 1000 men each; 6 divisions of light cavalry, comprehending 192 squadrons = 30,720 men; 6 divisions of foot artillery with 90 batteries, and six brigades of horse artillery with 12 batteries. All these are echelloned in a semicircle round the frontiers of the Russian empire, beginning at the Baltic provinces, then passing through Poland and Bessarabia, and along the shores of the Black Sea and the Sea of Azoff, up round to Moscow.

The Great Cavalry Reserve, in these parts, comprehend cuirassiers, light cavalry, dragoons, hulans, hussars, mounted pioneers and mounted batteries, to the number of 40,000 sabres and 128 guns. Thus the great army consists of 386 battalions of infantry, or 386,000 men; 469 squadrons of cavalry, or 79,720 sabres; and 100 batteries of artillery, or 1200 guns—say, with artillerymen, miners, sappers, &c., half a million men.

The European Army of Reserve remains, as in 1842, at 182 battalions, or 182,000 men; 128 squadrons of cavalry, or 20,480 men; and 472 guns.

The Caucasian Army numbers 81,167 men of all arms—that of Trans-Caucasia 80,000. 16 battalions and 1 brigade of artillery compose the Finland army corps; 16 battalions, 1 brigade of artillery, and 16 regiments of Cossacks of the Ural, form the army corps of Orenburg. The Siberian army corps consists of 16 battalions and 1 brigade of artillery. The various corps of Cossacks number 50,000 men. A great war reserve is forming by a most extensive levy; and there are 60,000 veterans and invalids in the empire.

The system of recruiting in Russia is exceedingly autocratical. When new levies are wanted, orders are issued to the headmen of villages; each of which is required to furnish a certain number, according to the amount of its population. The selection is made by the headman, who is perfectly absolute in the matter; and Jews are now obliged either to serve or pay for substitutes, who are not easily procured in a country like Russia, where so few of the lower class are their own masters. Formerly it was very difficult

[1] *Replique à la Réponse de M. Magnier aux Observations d'un officier d'état-major Russe sur la dernière campagne de Turquie*, par J. Tolstoy, ancien officier d'état-major Russe. Paris, Ledoyen, 1829. *Dix chapitres sur la Guerre d'Orient.* Paris, Delaunay et Dupont, 1829.

to prevent the men from deserting on the road to the depôts; since the circumstance of being selected as a soldier was considered as tantamount to perpetual banishment from family and friends. Hence, it was no uncommon spectacle to see numbers of these wretched serfs fastened together like a cordon of felons going to the hulks, or tied on telegas or carts, and thus conveyed to the depôt. But since leave has been given to soldiers to visit, at intervals, their native villages, and the period of service has been limited to 20 years, the dislike to the army has begun to abate, and recruits show less disposition to desert, although the military profession is still sufficiently unpopular. When the recruit, or rather conscript, arrives at the depôt, he is immediately stripped, washed, and shaved. If he wishes to retain any article of the dress which he brought with him, he is obliged to purchase it back. The only thing he is allowed to retain, without paying for it, is the cross of silver or brass which he wears round his neck. This superstition spares him as the only consolation of his miserable existence; and because, however passive in other respects, the most abject serf would become dangerous if deprived of an emblem which had probably been handed down from father to son for many generations, and the loss of which is considered the greatest misfortune.

The Russian soldier is docile, submissive, and brave. Like all slaves, he is supple, subservient, and cunning; like all natives of the northern regions, he is hardy, patient, and enduring. He has no other thought than to do implicitly as he is desired; and there is a pertinacity in his nature which inclines him to persevere, or to stand firm, as the case may be, without troubling himself about consequences. His courage is the result of insensibility rather than of moral force of character; and hence it is commonly more of a passive than of an active character. But there is, nevertheless, an element of indomitable ferocity in his composition: amidst all the apparatus and parade of civilization he is still three parts a barbarian. Hence his most brilliant achievements have been performed under men upon whom the force of civilization had made as little impression as on himself, and whom the instinct of sympathy had taught to develop his natural barbarism. The Italian campaign of Suwaroff affords a striking illustration of this remark. When that "hero-buffoon" arrived in Italy at the head of his 20,000 Russians to take the command-in-chief of the allied forces, General Chasteler, head of the staff of the army, proposed to him to make a *reconnaissance* of the French, who had retired behind the Oglio. "Des reconnaissances!" exclaimed the Muscovite chief, "je n'en veux pas; elles ne servent qu'aux gens timides, et pour avertir l'ennemi qu'on arrive; on trouve toujours l'ennemi quand on veut. Des colonnes, la baïonnette, l'arme blanche, attaquer, enfoncer,—voilà mes reconnaissances!" At Novi, at the Trebbia, and during his extraordinary campaign in the mountains of Switzerland, this wonderful barbarian, who had the instinct of genius, and a *coup d'œil* which has never been surpassed, proved that these were not empty words. By a kind of rude but infallible inspiration he discerned intuitively the true strategic points on which to move; and by the spell of his genius he rendered the Muscovite soldier invincible. In the campaign of 1812, we find another, though less striking, illustration of this peculiar characteristic of the Russian troops. Barclay de Tolly, a foreigner[1] in character and feeling, commanded in the early part of it; displaying a watchfulness, a prudence, and a sagacity in divining the intentions of his adversary, which proved him a great master in the art of war, and, beyond all question, saved the Russian empire. But still the army was discouraged; and Alexander felt it necessary to place at its head, as well as second in command, two of the ancient companions in arms of the conqueror of Italy. Its courage instantly revived; and the bloody day of Borodino, attested how well it repaid this compliance with its wishes. From that day onward—inspired by success—the Russian army has acquired a solidity of character which has rendered it formidable to its enemies wherever it has appeared in the field. Before its numbers, its perseverance, and the skill of its generals, the last remnant of Polish independance was extinguished in 1830–31. Turkey and Persia have felt its terrible influence since the Emperor Nicholas succeeded to the imperial throne; the Caucasian range has been penetrated, and the Usbecs have learned that wide wastes present no obstacle to the advance of the forces of a European monarch bent on conquest. But perhaps it was in the defence of Sevastopol that the severe discipline, the untiring energy, the profound science, the patriotic devotion, and the indomitable valour of a Russian army were most powerfully developed. The rapidity with which earthworks of the most formidable and complete character were raised for the defence of the beleaguered town, excited the astonishment, and for a long time baffled the efforts of the allies. The results of the terrible bombardment of a day were effaced in the course of a single night. Nor was it only in the engineering skill of the Russians that the stubbornness of their defence was manifested. Their sorties were numerous and distinguished by a rare audacity; and when at length the daring and constancy of the French and English triumphed over their honourable obstinacy, they crowned their steady resistance by a retreat calmly effected across the harbour on a bridge of boats and rafts constructed in the face of an enemy's fire.

The Russians have a strongly-marked national character, which foreigners can never duly appreciate; nor will its best energies be displayed in war, except under the command of men who feel its influence as powerfully as the meanest soldier in its ranks. The moral force of their army consists in a certain nondescript fanatical ferocity, which such men as Suwaroff, Bagration, and Kutusoff can alone fully develop.[2]

Be it said, however, in all justice, that the leaders who

[1] He was of Scottish descent.

[2] Lieutenant-General Baron Jomini describes the Russian soldier with that predilection in his favour which may not unnaturally be expected from the *aide-de-camp general de S. M. L'Empereur de Russie;* and *grand croix de plusieurs ordres.* But even while he paints *en beau* that infantry "qui avait prouvé à Pultava, à Kunersdorf, à Choczim, à Ismaël, et dans mille actions contre les Turcs ou les Suedois, ce qu'on peut attendre de son inébranlable fermeté," he shows his usual discrimination of military character, and makes several observations which appear to us equally striking and original. "L'opinion géneralement accreditée en Europe," says he, "que le paysan Russe, ne possédant rien, gagne beaucoup à devenir soldat, est denuée de fondement. Un grand nombre d'entre eux, outre les champs de ses maîtres, cultive des fruits, des légumes, travaille et trafique à son compte. Beaucoup sont à leur aise; et la vie du soldat dans l'interieur du pays, ne leur porte pas envie au point de la désirer. Mais quand ce paysan est sous les drapeaux, il s'y attache comme à une seconde patrie......Elevé de la manière la plus rude, sous un climat terrible, il est le plus robuste de l'Europe, le plus capable de soutenir les fatigues et les privations. Il ne connaît rien de plus sacré que ses devoirs; soumis à l'ordonnance comme aux précepts de sa réligion, aucune fatigue, aucune intempérie, ne peut lui faire négliger les obligations qu'elle impose. On voit dans toutes les marches et durant une campagne entière, le cannonier près de sa pièce, au poste qui lui est assigné par le réglement, et à moins d'être frappé par le fer ennemi ou autorisé par son chef, il ne la quitterait pour rien au monde. Le soldat du train cire son harnais au bivouac par 15 degrés de froid et aux jours fixés, comme il le ferait dans un bon cantonnement pour aller à une parade. Cet esprit admirable d'ordre et de précision, joint à l'instinct naturel que le soldat a de se pelotonner au lieu de fuir quand il est enfoncé, rend les défaites extrémement rares. Sans doute, une telle troupe est moins facile à rallier sur le terrain qu'une armée Française, où l'intelligence du soldat supplée souvent au défaut d'ordre; mais elle est aussi plus difficile à rompre......Cet instinct qu'aucune des troupes de l'Europe

are the most conspicuous in the defence of Sevastopol, and the prosecution of the last campaign in Asia, distinguished themselves as much by their harmony and courtesy as by their courage and intelligence. The most enlightened British and French generals found honourable emulators in Prince Menschikoff, Prince Gortschakoff, and General Mouravieff.

Swedish army.

In Sweden, union and confidence have always subsisted between the soldier and the citizen; and hence the desire of military service is so common among all classes of the nation, that sending a man to the army is not there, as elsewhere, a punishment. In 1811, when the peasantry broke out in insurrection against the conscription by ballot, they offered to take arms without exception in the event of war, to submit to be drilled together in time of peace, and to equip themselves at their own charge, provided the obnoxious innovation was abolished; tenders which were wisely accepted on the part of the government. The present military establishment of Sweden is considerably below what a nation constitutionally warlike might be supposed to maintain; but as the aim of the government is to husband the public money, and, if possible, to relieve the country from the pecuniary difficulties entailed upon it by the folly and extravagance of the ex-king, all the departments of the public service have been placed on the most economical footing. The actual standing army, accordingly, does not exceed 35,000 men of all arms. The militia, however, is more numerous; and, from the peculiar aptitude of the Swedes for military exercises, it exhibits a very soldier-like appearance, though only trained for a few weeks annually. Like the regular army, it is composed both of horse and foot, and must afford a ready resource in the event of war. The organization of the whole is excellent. The regiments of the line are recruited neither by voluntary enrolment nor by conscription, but by a kind of intermediate system; every landed proprietor furnishing a certain number of soldiers, to each of whom a house and a portion of land are allotted for his maintenance. The Swedes have been long and justly celebrated for their martial qualities; and no modern nation of so small extent has made so conspicuous a figure in history. They are brave, hardy, and naturally heroic men; of superior physical and corresponding moral power; and, as soldiers, equal to any in the world.[1]

Danish army.

The Danish army consists of rather more than 30,000 men, with a reserve of about 14,000. Of this force 2157 are divided throughout the kingdom of Denmark, and 9655 stationed in the duchies; while the remainder are employed in garrison, or occupy cantonments in the vicinity of the capital. The whole is composed of a staff of 23 officers; a corps of engineers of 32; an artillery corps of 3202 men, divided into 22 companies; 6126 cavalry, divided into ten regiments, one of which is a regiment of guards; 13,412 infantry, divided into thirteen regiments of two battalions each, one of which is also a regiment of guards; 2753 chasseurs, divided into five battalions of four companies each; and, lastly, a rocket corps, amounting to 156 men. The two regiments of guards are composed of very fine men, and have a noble appearance. The artillery consists of twenty batteries of eight pieces each; besides a company of sappers and miners, one of pontoon men and pioneers, with a detachment of artificers, and a laboratory establishment.

The Danish soldier is a quiet, hard-working man, who goes about the peasant's farmyard like one of his own farm-servants, puts up with the same fare and lodging, looks after the cattle, feeds the pigs, and makes himself useful. The Danish service was notorious formerly for the barbarity of its discipline. The slightest error in observing the most absurd regulations in dress and drill incurred the most severe corporal punishment. The cane of the under-officer was incessantly at work on the shoulders of the wretched soldier. It was not uncommon sixty years ago for the men to sit up all night previous to a grand review, to tie their queues, powder their hair, and save it from being deranged by lying down; as the slightest derangement or want of uniformity in pigtails or sidelocks brought down severe punishment. Suicide was frequent; and officers as well as men were brutalized by the cruelties they had to witness, inflict, and suffer. The late king, Christian VIII., abolished entirely, and at once, the infliction of corporal punishment at the discretion of officers and under-officers. The minor military transgressions could only be punished by arrest, extra duty, and such punishments as are now adopted in our army; flogging and caning were abolished. The officers of the old school of military discipline and dress, the martinets of the parade-ground, predicted the entire ruin of their well-drilled, well-cudgelled little army, by these innovations. The men were no longer enlisted for life. They served only three years, after which, those who wished to become under-officers, served two years in a military school, and three years afterwards as under-officers; and eight years concluded their term of military service, unless they chose to re-engage. The clothing, dress, drill, were simplified; and the Danish soldier is now scarcely distinguishable from the Prussian or other German soldiers. The Danish army is composed of peasants accustomed to hard work, from the great exertions which their climate imposes on the husbandman to get his seed into the ground in due season. Wet and cold and night work, hardship, and labour, are familiar to them; and the Jutlanders, in particular, are men of greater physical powers, and more roughly bred and fed, and hardier than the peasantry of Holstein, or of the south of Schleswig. The Danish soldiery, and the classes from which they are drawn, are, at this day, men of the same character as the peasantry of the feudal ages. They have the same implicit confidence in, and personal attachment to, their leaders. Their captains, lieutenants, and under-officers are to them what the baron, his standard-bearers, squires, and pages were to their forefathers. Their relation is preserved in the army from the men and officers growing up together in the same regiment, and becoming known to each other. Officers are rarely shifted from the regiment in which they have begun their service, and regiments are rarely removed, in time of peace, from the province in which they have been first raised or quartered. The Danish soldier, like the peasant in the days of chivalry, thinks the real battle is but beginning when, in most modern armies, it is considered ending—when the combatants come hand to hand in the charge of bayonets. The firing is considered a mere preliminary, however bloody; and at Idstadt, and again at the siege of Frederickstadt, during the war with Prussia, regarding the duchy of Schleswig-Holstein in 1849-50, the Danish troops slackened, and even ceased their fire altogether, on command—a manœuvre, in face of the enemy, and in the heat of an engagement, which few troops of the most highly disciplined armies would have the coolness to practise, or their commanders the confidence in their men to venture upon. But the implicit confidence of the Danish soldiery in their leaders, and of the leaders in their men, and their military intelligence and submission to

ne possède au même degré, s'est fortifié chez les Russes par les guerres contre les Turcs. Là, tout fuyard est sabré par les nuées de cavaliers qui se répandent sur les flancs et les derrières de l'armée. Ce n'est qu'en restant fermes et réunies qu'on échappe à une destruction inévitable." This is a tolerably good reason for the "instinct" of which the gallant author speaks. He adds, "La plus parfaite egalité règne dans l'armée, car une fois dans la carrière des armes, aucun obstacle n'empêche de la parcourir. Pour s'en convaincre, on n'a qu'à voir les noms des généraux distingués dans l'histoire militaire de Russie; on y trouvera autant de plébéiens, ou de bas-officiers parvenus par leur mérite, que dans tout autre pays." (*Guerres de la Révolution*, tom. i., p. 254–256.)

Army.

orders, seem innate. Their ideas of warfare are formed on the tales and ballads of the times of chivalry, when personal combats decided battles; and no country is so rich in popular songs and traditionary stories, from the fourteenth and fifteenth centuries.

Waldemar Scier (the Victorious), his good queen Dagmal, the wars in the unhappy times of his sons, and of Eric of Pomerania and his gallant queen Philippa, the sister of our Henry V., and the exploits of the knight Ebbesen, and his battles against the Holstein Count Gert, are household literature among the Danish peasantry, and, as far as literature can do so, have formed the character of the people. The Danish soldiers are men of the fifteenth century, led by officers of the nineteenth. The under-officers appear to stand on a higher footing in the Danish service than the non-commissioned in ours. They are appointed in the same way, by the recommendation of the captain of the company, and are selected from the soldiers of three years' service. On their appointment they are sent for two years to the military academy, where they are instructed in various branches of knowledge connected with military duty, which they could not be taught so well with their regiments. Outpost-duty, patrol-duty, and all that depends upon the military intelligence and eye of the under-officer, was done in a more satisfactory manner in the Danish than in the insurgent army. The latter was under great disadvantage in the field from want of experienced or instructed under-officers, and officers who understood and had the confidence of the men. The defeat of the "Schleswig-Holstein" army is attributed to this want by the German officers who have written on the war. The Danish non-commissioned officers have the moral weight of a better educated class, as well as that of their military rank, among the men. The officers are highly-educated, gentlemanly men, superior in tastes and acquirements to the majority of our officers, their education being very much superior. They are all bred from a very early age at the military academy of Copenhagen, in which the languages and literature of other countries, as well as of their own, and all the mathematical and other sciences connected with the military profession, are very carefully taught, and they undergo very strict examinations before they pass as cadets. They join a regiment as privates in the ranks, rise to be under-officers, in which rank they remain for two or three years, and are appointed second-lieutenants afterwards, and rise by seniority in regimental rank. Captains and subalterns, both in cavalry and infantry regiments, are, in general, as young men for their rank as officers in our service. The military officers are often provided for, after long and meritorious service, by offices in the customs or the forest department. The subaltern officer is not allowed to marry unless he can prove that, besides his pay, he and his proposed wife have an income of 600 dollars; and he must also insure his life to the extent that his widow may enjoy an annuity equivalent to his pay. The pay is small; about 400 dollars yearly, or about L.45 sterling, is the pay of a lieutenant: but, on actual service, the officer has a field allowance, and living is extremely moderate. It is not merely the cheapness of provisions, but the simpler habits of living that make one country less expensive than another. The officer in Denmark maintains his station in society on his small pay, and is, in manners, appearance, education, and all gentlemanly accomplishments and feelings, equal to the best of our own regimental officers, and very superior to the many ignorant, uninformed youths who formerly joined our regiments without any preparatory education or examination. The artillery of the Danish army is said to be excellent; and ball practice with artillery is even a favourite amusement, on summer evenings, with the citizens of Copenhagen. In the Danish dominions the inhabitants of the great towns are exempt from the conscription for the landwehr, or general military service, but they furnish battalions of local militia, which do military duty in the town as part of the garrison, and which elect their own officers, up to captains inclusive, and are clothed and equipped at the expense of the corporations. They are a kind of volunteer force, but liable to serve, in the event of an invasion, like other troops, and then receive pay, subsistence, and quarters, according to their rank, like the officers and men of the regular army. The artillery of the city of Copenhagen was called out in the last war; and the "shoemaker's brigade," as it was called by the soldiers, from its captain being a respectable tradesman of that craft, an amateur artillerist, was as well served, and as effective in the field, during the three years of warfare, as any brigade of guns in the army.[1]

Saxon army.

The electorate of Saxony, with a superficies of 717 square miles, a population of 2,104,336 souls, and a revenue of about 780,000 thalers, maintained in 1792 an army of about 32,000 men, being a 66th part of the population; and on this footing it remained till 1800, when it was increased to 38,000 men, being a 56th part of the population. But Saxony having in 1802 gained a small increase of territory in consequence of the treaty of Luneville, though, at the same time, it lost about 1,778,000 thalers of revenue, the army was reduced to 31,000 men, of which 22,000 were infantry and 6700 cavalry. This state of things continued until 1806, when the military force was raised to 36,000—Saxony having then a population of 2,276,000 souls. In the year 1809 she furnished a contingent to France of 16,000 men, who, under the command of Bernadotte, afterwards king of Sweden, took part in the memorable campaign of that year, and fought at the battle of Wagram; but the Emperor Napoleon was so little satisfied, either with the conduct of these troops, or that of their leader, on this occasion, that he was with difficulty prevented from stigmatizing both in the orders of the day. After the peace of Vienna in 1810, the Saxon army was reorganized upon the model of the French, and its contingent of 16,000 men formed the seventh corps of the grand army which invaded Russia in 1812. It was commanded by General Reynier. On the disastrous termination of the Russian campaign, its wrecks, reorganized from the troops remaining in Saxony, entered into line in 1813, after the battle of Lutzen; and on the conclusion of the armistice with the Hessian corps and that of General Durutte, it formed again the seventh division. The defection of the Saxon divisions at Leipzig, on the 18th of October 1813, is well known. The king of Saxony having lost his liberty in consequence of the result of that disastrous day, his army was dissolved and replaced by a landwehr of from 10,000 to 12,000 men, which followed in the train of the allied armies when they invaded France. In 1815, however, the army was reconstituted to the extent of a third of its former strength; and underwent various changes until 1824, when it was placed upon a still better footing. During the past two years it has been further strengthened to meet possible exigencies. The *infantry* at present (1856) consists of four brigades of infantry of four battalions each, making 15,748 men and officers; a brigade of chasseurs of four battalions of four companies each, or 4005 men. The *cavalry*, which formerly consisted of horse guards, cuirassiers, hulans, and hussars, has been transformed into four regiments of light horse, consisting of four squadrons—in all 3208. The *artillery* consists of one regiment making twelve companies, two of which are horse, amounting to 2420 sub-officers and soldiers, together with a train of 189 men and as many horses. A dozen officers without troops, and a company of sappers 67 strong, compose the *engineer* department. The institutions connected with the army are a school for cadets, and a military academy, both at Dresden. The reputation of

[1] *Denmark and the Duchies*, by Samuel Laing.

the Saxon infantry is low; but the cavalry is better than the infantry, and is well qualified for the service of the advanced posts, which was its usual destination under Napoleon.[1]

Hanoverian army.

The composition of the Hanoverian army is as follows:—The *infantry* consists of eight regiments of two battalions each, and two light infantry regiments. There are two of these regiments guards; and the whole are divided into three brigades, the first consisting of five regiments, the second of four, and the third of three. There are six regiments of *cavalry*, two of cuirassiers of the guard, two of hussars, and two of dragoons; and each regiment is composed of four squadrons, 48 officers, 433 men, and 403 horses. The *artillery* consists of one brigade divided into ten companies, one of which is horse, and contains 70 officers, 1449 men, and 210 horses. The corps of *engineers* and artificers consist of 198 officers and men. The artillery is of the English model and calibre, and its batteries, both horse and foot, consist of six pieces and a howitzer each. The total strength of the army, including the staff, amounts to 24,197 men and officers. The period of service in the infantry of the guard is four years only, but in all the other corps six years. The cavalry and artillery are recruited as much as possible from volunteers. The Hanoverians make excellent soldiers; and it is well known that, during the Peninsular campaigns, no part of the Duke of Wellington's army more frequently distinguished itself than the King's German Legion, which was almost exclusively composed of Hanoverian volunteers.[2]

Bavarian army.

The Bavarian is one of the largest of the third-rate armies. Its *infantry* consists of a regiment of grenadiers of the guard in three battalions, of 16 regiments of the line in two, and of six battalions of chasseurs—presenting an effective force of 41 battalions, or 58,560 men. Its *cavalry* is composed of eight regiments, in seven squadrons each, forming a total of 56 squadrons, or 11,584 men, and horses in proportion. The *artillery corps*, commanded by a lieutenant-general, consists of two regiments of cannoneers of 15 batteries, one regiment of horse artillery, and two divisions of artificers, pontoniers, sappers, and miners—making a total of upwards of 11,000 men. The *engineer corps* is composed of a general, a colonel, a lieutenant-colonel, two majors, two captains, eight lieutenants of the first class, eight of the second, and six conductors, and is divided among the five directions of Munich, Augsburg, Nuremberg, Wurtzburg, and Lindau. The Bavarian army, therefore, consists in all of 91,452 men. Every Bavarian, the clergy only excepted, is obliged to bear arms in defence of his country; but, in practice, students and persons necessary to their families are usually exempted; and permission is likewise granted to serve by substitute. The method of recruitment is conscription. Besides the permanent army, there is a reserve destined to reinforce it; and, in the event of war, the landwehr may be equally called upon to support the army, when reinforced by the battalions of the reserve, but only in the interior. The *landwehr* is divided into two classes, one of which comprehends those who are least capable of performing active service, and who cannot in any case be employed beyond the limits of their district. In time of peace it co-operates in the maintenance of public tranquillity, when put in requisition for that purpose, and when the troops of the line are deemed insufficient. The reserve and the landwehr amount to 70,000. The Bavarian army is well organized, and has always maintained a respectable character for discipline and bravery. The cavalry is considered superior to the infantry.[3]

Armies of Wurtemberg and Baden.

The small army of Wurtemberg requires only a brief notice. Its *infantry* consists of 8 regiments of 2 battalions, divided each into four companies; its *cavalry*, of a squadron of guards, a squadron of chasseurs, and 4 regiments of horse, each divided into 4 squadrons; its *artillery*, of a regiment of 6 companies, 3 horse and 3 foot, besides a garrison company; but it has no engineer corps distinct from that of the artillery. Its peace establishment is composed of 9189 combatants, and 1806 horse: on a war footing it would amount to 22,000 combatants. The Wurtemberg army is recruited by voluntary enrolment and forced levies. The military age is from 18 to 30 for enrolment, and from 20 to 25 for levies; and, in both cases, the élite of the population only is taken. This little army is well officered, and enjoys some consideration. The grand duchy of Baden, the seventh state of the Germanic confederation, has a superficies of 279 square miles, with a population of 1,356,943 souls, and supports a military establishment of 15,000 men, although it is only bound to furnish a division of 10,000 men (the 2d of the third corps) as its contingent.[4]

Army of the Germanic confederation.

The organic law of the military constitution of the Germanic confederation, adopted on the 9th April 1821, in the fifteenth full sitting of the diet, and forming the basis on which the federal army has been organized, is exceedingly complex, and altogether unsusceptible of analysis within the space which the limits of this article afford. Its leading provisions, however, may be shortly stated, and are as follow:—The army of the confederation is composed of the contingents of all the states members thereof, raised according to the formation of their particular *matricule* or computation in the diet. The proportion of the different arms is regulated conformably to the principles of the new tactics. The federal army is formed of corps d'armée of a single nation or of combined corps, and both are subdivided into divisions, brigades, and regiments. No state of the confederation, whose contingent forms one or more corps d'armée, can combine contingents of other states with its own in the same division; and the states which have corps or divisions combined, concert together the manner of forming and organizing them; and in case of dispute, the diet decides. In the organization of the federal army regard is had to the interest resulting from the particular relations of different states, in as far as can be done consistently with the general object of the confederation; and as the rights and duties of all the confederate states are the same, it is specially provided that every appearance of supremacy on the part of one state over another is to be avoided. The contingent of each state must always be completely equipped and ready to take the field as soon as it shall be called to do so; but the force and assembling of the army to be raised, as well as of the reserve, are regulated by particular dispositions of the diet. 1. The ordinary contingent of each state is one-hundredth part of its population, conformably to a table prepared and rectified from time to time by the diet. 2. The proportion of the cavalry of the federal army is fixed at one-seventh of the total of the troops; and two field-pieces are required for every 2000 men of the contingent, besides one for every 1000 of the reserve in arsenal. 3. The federal army consists of 10 corps d'armée, 7 simple and 3 combined, designed in the order of the digits or primary numbers; and every corps has at least 2 divisions, each division at least 2 brigades, each brigade at least two regiments, each regiment of infantry at least two battalions of 800 men each, and each regiment of cavalry at least 4 squadrons of 140 men each. The *minimum* of a contingent of cavalry is 300 horse; of

Army. infantry, 400 men; and of artillery, a battery of six or eight pieces. 4. As the contingent of each state must be ready to take the field in a month after it is called upon, all the *matériel* of armament and provisions necessary for the contingent must be deposited in the arsenals of each state, and all the contingents of the army must be kept up to their full complement even in time of peace. 5. The generalissimo of the confederation is chosen by the diet in ordinary assembly, and his functions cease when the federal army is dissolved. 6. The commanders of the corps of every nation or state have the rights which the sovereign whose troops they command may think proper to confer upon them, without deviating from the principles upon which the military constitution is founded. There is a great number of other dispositions and regulations, touching a variety of matters; but those above specified are the principal, and may serve to convey an idea of the military constitution of this great confederacy, organized in imitation of that which, while it seemed to strengthen the hands of Napoleon, proved eventually, by the defection of its members, one of the chief causes of accelerating his fall.[1]

Netherlands armies. The military power of the United Provinces dates its commencement from the middle of the fifteenth century, when, after a long and sanguinary struggle, they succeeded in emancipating themselves from the yoke of Spain; and in the following century it received considerable development in consequence of the wars which they had to maintain against Louis XIV. In 1702 they had in their pay upwards of 100,000 men, exclusive of 30,000 who were in the service of the Dutch East India Company. But this period may be regarded as the highest condition of the army of Holland, which subsequently declined both in number and reputation; so that in 1775 it did not exceed 30,000 men, fully one-third of whom were foreigners. In 1789, Holland, with a population of 2,340,000 souls, inhabiting a country of 625 square miles, supported an army of 36,000 men, consisting of 40 regiments of infantry and 10 of cavalry; and with this force it joined the first coalition against the French republic. In 1792 the Dutch army had been increased to 39,000 infantry, 3450 cavalry, 1560 artillery, and 260 miners and pontoniers; making a total of 44,270 combatants. But in the campaigns of 1793 and 1794 they afforded the Prince of Orange occasion for displaying considerable military talents, put his army to a decisive test, and impressed all with a conviction that its degeneracy in moral force was equalled only by the radical defects of its organization. The conquest of Holland by the French, however, was followed, in 1795, by the re-organization of the army on new bases; and so great was the effect of the changes thus introduced, that the Batavian troops, led by Dumonceau and Daendels, rivalled the French, by whose side they fought, both in discipline and valour; and at Alkmaër, on the Rednitz, and on the Danube, bravely upheld the ancient reputation of the Dutch arms. At the peace of 1815, Belgium having been united to Holland in order to form a constitutional monarchy, and England having restored the greater part of the Dutch colonies which had fallen into its hands during the republican and imperial regime, the new kingdom of the Netherlands at once, and as it were *per saltum*, took its place among states of the second order, with a continental superficies of 1165 square miles, and a population of 6,166,854; and lost no time in organizing a military system suited to its position and rank among the nations of Europe.

Belgian Army.—But, in 1830, a revolution having broken out in France, its influence extended to Brussels. The Belgian provinces were severed from the crown of Holland in August of that year. In July of the following year (Belgium having in the meanwhile assumed a republican form) the allied powers of Europe recognised the independence of the state, and it was declared a kingdom—Prince Leopold of Saxe Coburg being elected to the sovereignty. A soldier himself, and aware how much the Belgian frontier was exposed to aggression, he paid great attention to the constitution of the army; and at this moment it rivals, in discipline, order, and intelligence, the best armies in Europe. The force was fixed in 1836 at 42,000 men, but its numbers vary with the appearance of danger; and at this time (January 1856) it is composed of 73,718 men and 10,600 horses. The force is divided into infantry of the line, carabineers, grenadiers, horse and foot chasseurs, lancers, cuirassiers, guides, gens-d'armes, and a considerable train of artillery, sappers, miners, &c. There is likewise an extensive general staff, a staff corps, a provincial staff, an administrative service, and a health establishment. The general staff comprises 9 lieutenant-generals and 18 major-generals in active service; 2 lieutenant-generals and 4 major-generals in reserve. The staff corps consists of 12 superior and 40 subaltern officers. The provincial staff comprises 5 commandants of provinces (generals or colonels), 21 commandants of fortresses, and 35 fort-adjutants. In the administrative service are—1 superintendent-in-chief, 1 first-class and 4 second-class superintendents, and 16 sous-intendants or inferior superintendents; 29 captains quartermasters, 61 paymasters, and 29 barrackmasters. The health service or medical department is composed of 1 inspector-general, 4 surgeons-in-chief, 7 garrison surgeons, 28 regimental surgeons, 29 surgeons of battalions of the first-class, and 38 ditto of the second, 20 assistants, 1 principal physician, 30 physicians of three classes, 1 veterinary inspector, and 27 veterinary surgeons of the first, second, and third class.

The infantry consists of 1 regiment of carabineers, 2 of chasseurs, 1 of grenadiers, and 12 of the line. These regiments are divided into three active and two reserve battalions each, the carabineers having four battalions of the one and two of the other. There are likewise two stationary companies (*compagnies sedentaires*), one disciplinary division, and one company of enfants de troupe. The staff of each regiment is composed of 1 colonel, 1 lieutenant-colonel, 1 adjutant-major, and 2 paymasters. Each service battalion has 1 major and 1 adjutant; each reserve battalion 1 major and 1 paymaster; each active company contains 1 captain, 1 lieutenant, and 1 sub-lieutenant; each reserve company 1 captain and 1 lieutenant; and each depôt company 1 major, 1 captain, 1 lieutenant, and 1 sub-lieutenant.

The *Cavalry* is composed of light and heavy. The former are divided into 2 regiments of dragoons and 2 of lancers, each of 6 active and 1 reserve squadron; and the latter consist of 2 regiments of cuirassiers of 4 active and 1 reserve squadron; and a regiment of guides of 6 active and 1 reserve squadron. The staff of each regiment consists of 1 colonel, 1 lieutenant-colonel, 2 or 3 majors (according to the number of squadrons), 1 captain and adjutant, 1 lieutenant-adjutant, and a paymaster. The squadrons comprehend each, 1 captain, 1 captain *en second*, 2 lieutenants, and 2 sub-lieutenants; and the depôt squadron line, 1 captain instructor, 1 captain commandant, 1 lieutenant, and one sub-lieutenant.

The *Artillery* consists of a staff of 14 superior and 19 subaltern officers, 9 commandants of artillery, and 24 *gardes d'artillerie*. There is one regiment of horse-artillery, divided into 4 field and 6 siege batteries; and 3 regiments of foot artillery, each containing 5 field and 6 siege batteries; a company of pontoniers, a company of artillery artificers, one of armoury artificers, and a field train. The staff of a regiment consists of 1 colonel, 1 lieutenant-colonel, 3 majors, 1 captain and adjutant, 1 lieutenant and adjutant, 1 captain instructor, and 1 paymaster. Each horse battery comprehends 1 captain commandant, 1 captain *en second*,

[1] *Bulletin des Sciences Milit.* tom. ii., p. 45. *Loi Organique de la Constitution Militaire de la Confédération Germanique*, 1821.

Army.

2 lieutenants and 2 sub-lieutenants; each battery of foot artillery has a captain commandant, a captain *en second*, and 3 lieutenants or sub-lieutenants. A siege and depôt battery consist of 1 captain commandant, 1 lieutenant, and 1 sub-lieutenant. In the pontoon company are—1 captain commandant, 1 captain *en second*, 2 lieutenants, and 2 sub-lieutenants. Each company of artificers contains 1 captain commandant, 1 lieutenant, and 2 sub-lieutenants. The field train contains 1 captain, 1 captain *en second*, and 3 lieutenants or sub-lieutenants.

The *Engineers* are composed of a staff of 13 superior and 47 subaltern officers, and a regiment of 2 battalions; each battalion consisting of five companies. The staff of the regiment consists of 1 colonel, 1 lieutenant-colonel, 1 captain and adjutant, 1 paymaster; each battalion has one major and an adjutant; and each company is composed of 1 first and 1 second captain, 1 lieutenant and 1 second lieutenant. The administration comprises 12 directors of hospitals, 12 sub-directors, 256 hospital employés, 16 directors of the bakery, and 136 employés therein.[1]

But besides the regular army, the whole country is formed into a civic or national guard of 600,000 men. It is divided into three corps or *bans*, each of which is subdivided into legions, and the whole guard is raised in the different provinces in just proportions. There is no time lost in the Belgian army; a course of military instruction, of every description, of the most practical utility, being unceasingly pursued the whole year round. In winter, when the troops leave the camp, their marching *out* commences, and these marches are about 10 miles out and 10 miles in. They never neglect a single opportunity of brigading these regiments in the different garrisons; it being a standing order that brigade field-days should take place regularly twice a-week, even where only two regiments are quartered together. Major Harvey, on the staff of the late Lord Frederick Fitzclarence, who had an opportunity of seeing the Belgian army in one of its camps of instruction, says, "I personally accompanied the general in going round the line of sentries; and was permitted to put many questions as to his method of completely protecting his front and flanks. The regiment of lancers, under the command of Colonel Bester, attached to this brigade, admirably performed their part, scouring the roads in every direction, and sending in continual reports from their different patrolling parties, their videttes being posted with consummate judgment and intelligence. Nor can I pass over my astonishment at the energy and rapidity with which the column of infantry, composed of such young soldiers, pushed forward through a deep sandy 'defile' of two miles in length; nor how thoroughly they seemed to understand and execute the principles of squeezing as large a front as possible over and through the different obstacles they met with, preserving their original extent of front up to the very last moment, by which means the tail of the column was always in its right place, and not a straggler lagged behind. In short, I never remember to have seen the spirit of General Craufurd's light division orders for the line of march more rigidly adhered to, or more admirably carried out. But whether in the mere pipeclay and parade movements in the open plain, where accuracy and uniformity of execution formed the principal features, and where General L'Oliver's remarkable skill in handling his troops was so conspicuous, or in the more essential movements of a campaign, such as passages of *défilés*, combined movements by various columns directed on certain points, out-post duties, &c., there was an amount of intelligence and practical confidence throughout, which impressed me with the conviction that a small '*corps d'armée*' so well in hand, and so ably commanded, would feel themselves quite a match for a far more numerous, but less practised force."[2]

Army.

The Dutch Army.—The army of Holland is of nearly equal strength with that of Belgium, and has had the advantage of much careful drilling by Prussian officers. The militia, however, does not approach the numerical strength of that of Belgium. Holland rests her defensive strength upon her navy, and trusts to the influence of alliances for her internal tranquillity. The composition of the Dutch army corresponds with that of Belgium. The general staff consists of 10 lieutenant-generals and 16 major-generals, and the staff-corps of 7 superior and 19 subaltern officers. The staff of the provinces and strong places is composed of 10 commandants of provinces, 8 commandants of fortresses, and 29 fort-adjutants. The corps of "intendance" consists of 1 intendant-general, with the rank of general; 1 of the first and 1 of the second class; 2 sub-intendants of the first class, and 3 of the second class; 2 adjutants, 21 captains-quartermasters, 51 paymasters, 21 administrators of quarters. The health department consists of 1 inspector-general, with the rank of general, 1 inspector, 6 first-class health officers, 120 health officers, 27 physicians, and 3 veterinary surgeons. The total of the force is 1701 officers and 56,946 soldiers.

The *Infantry* is composed of one regiment of grenadiers and chasseurs (light infantry), divided into four battalions of 5 companies each; 8 reimgents of the line, each containing 4 battalions of 5 companies, and 2 depôt companies; 1 battalion of instruction, a depôt of discipline, and a recruiting depôt. The infantry officers are 866 in number, thus divided—2 superior and 25 subaltern, forming the staff; 5 superior and 74 inferior in the grenadier regiment; 48 superior and 672 subaltern in the 8 regiments of the line; 1 superior and 14 subaltern in the battalion of instruction; 1 superior and ten subaltern at the depôt of discipline; 1 superior and 13 subaltern in the recruiting department.

The *Cavalry* consists of a staff, 4 regiments of dragoons of 4 squadrons each, and 2 squadrons of the Limberg chasseurs, with 155 officers.

The *Artillery* comprehends 3 regiments of foot, and 1 of horse, a company of pontoniers, and 1 company of artificers. Each regiment consists of a staff, 5 horse batteries, 8 field batteries, 33 siege batteries, and 2 squadrons of a field train. The general staff comprehends 5 superior officers, 18 subalterns, and 32 *gardes d'artillerie*. The regimental staff of each regiment comprises 17 superior and 18 subaltern officers. Each siege battery has 1 captain and 3 lieutenants; and each field and horse battery 1 captain and 4 lieutenants and sub-lieutenants. The company of pontoniers is composed of 1 major, 2 captains, and 4 lieutenants and sub-lieutenants; the company of artificers of 1 captain and 6 lieutenants and sub-lieutenants; and the field train of 1 captain and 2 lieutenants.

The *Engineers* comprehend a battalion of 3 companies with 13 officers; and the staff consists of 88 officers.

Sardinian army.

SARDINIA is the Prussia of Italy. It has been from old times a military state in virtue of its geographical position between the two great military powers, France and Austria. Every Piedmontese (and this designation usually applies to the soldier of the Sardinian states) is liable to military service; and the man who has served his three years in the line remains disposable in case of war, for sixteen years to come.

Accustomed for ages past to these obligations, the Piedmontese has more military spirit than the Italian of any other district, and makes a good soldier. A nobility, numerous and brave, furnishes a body of officers worthy of command in such an army.

[1] *Journal de l'Armée Belge. Recueil d'Art, d'Histoire, et de Sciences Militaires.*

[2] *The Camp at Beverloo.* By Major H. B. Harvey, H.P., late Military Secretary to Lieut.-Gen. Lord Frederick Fitzclarence, G.C.H., Commander-in-Chief at Bombay.

Army.

The science of war is much cultivated at Turin; the artillery, both as regards theory and practice, is of the first class. It consists of 4763 privates, 331 officers, and 5 generals. The composition of the army is as follows:—30 generals, 3181 superior and inferior officers, and 44,413 rank and file. There are several brigades of infantry, each brigade consisting of 2 regiments, each regiment of 3 battalions, namely, 2 infantry of the line (5 companies each), and 10 jäger battalions of 4 companies. The brigades are designated Savoy, Piedmont, Aosta, Coni, Queen's, Cosale, Pignerol, Savora, and Acqui.

The infantry battalion, on its war footing, is from 1000 to 1100 strong, which gives to the whole infantry from 30 to 31,000 men. By calling in the reserves, this force may receive an accession of 10,000 men.

Of this infantry force, 3637 (about 10 battalions) are sharp-shooters—Bersaglieri (from *bersaglio*, an object aimed at). This body vies with the French voltigeur in activity, and with the heavy-armed Swiss rifleman in precision of aim, and is the admiration of all experienced judges. Marine infantry can also be applied on occasions of land service.

The cavalry consists of 4 heavy and 5 light regiments, numbering 315 officers, and 4896 privates. The regiments are named after certain towns and provinces—Royal Piedmont, Genoa, Nice, Savoy, Novara, and Aosta. Each regiment has about 600 horses. Its proper number for service, indeed, is 1000, but there is a difficulty in raising this amount, for the troop horses are generally imported from North Germany. Men and horses are fine in appearance. The lance was formerly confined to each fifth squadron, but of late all have been armed with it.

Besides these troops, there are royal carabineers, body guards, guards of the royal palaces, veterans, invalides, &c.

The engineer service is provided for by corps of sappers and miners.[1]

In the war with Austria in 1848, when the independence of Piedmont was threatened, the military prowess of Sardinia was powerfully displayed; but it was not until 1855, when 15,000 Sardinian troops joined England and France in the defence of Turkey against Russian encroachment, that an opportunity was offered of ascertaining, by comparison, the exact degree of their efficiency. It is hardly enough to say that they suffered nothing by the contrast. In many respects, their organization and equipment, their aptitude to meet the sudden emergencies of field service, and their admirable practice with rifle and ordnance, supplied examples of which the proudest military nations might avail themselves.

Neapolitan army.

The Neapolitan army is scarcely deserving of notice, either in a political or military point of view; for, next to the soldiers of his Holiness the Pope, those of Naples are beyond all dispute the worst in Europe. In 1792 the Neapolitan army amounted to 30,000 troops of the line, as they were called, and 15,000 militia—a force which was increased, in 1799, to 60,000 men of all arms; 40,000 of whom invaded the Roman states during the campaign of that year, and conducted themselves rather like banditti than a regular army. Formidable only to its allies, and to the country which it serves to retain in abject servitude, this army has since experienced the most violent mutations; but its number at present may be estimated at from 35,000 to 40,000 men of all arms.

Swiss troops.

The 24 cantons of Switzerland are defended in case of need by the militia, which, in fact, comprehends the whole of the adults who may either be actually in the country or elsewhere engaged. There are few Swiss who are not good soldiers, though no regular army is kept up; and so strong is their patriotism, that, when the fiery arrow goes forth, wherever they may be, they rally in defence of their native mountains.

The Swiss have for ages been the hirelings of Europe, either in public or private service, as soldiers, or as domestic servants. Pay has for ages been the only influence in general and constant operation on the Swiss mind, in every class of society, and has weakened the efficiency of any higher influence and feelings in affairs than self-interest—*Point d'argent, point de Suisse*, has extended from their military to all their social relations. A great proportion of the young men of Switzerland have small farms or houses, with portions of land, and rights to grazings in the Alp of their native parishes, to succeed to upon the death of their parents; but until that event in their social position, they are supernumeraries at home, their labour not being necessary for cultivating the paternal acres, and their subsistence costing more, perhaps, than the land can afford. They have no colonies to migrate to, no labour to turn to, except labour of skill, which all cannot learn or live by, and no considerable manufacturing employment, except in two or three cantons, to absorb their numbers; and they enlist, therefore, readily for a few years in Swiss regiments in foreign service. France, after the restoration of the Bourbons, had about 17,000 men of Swiss regiments; and the disgust of the French nation at the preference shown to these mercenaries was a main cause of the expulsion of Charles X. Naples has at present 4 regiments of these mercenaries; Rome as many; and England has a Swiss legion. It is reckoned that from 8000 to 10,000 Swiss are in foreign service at present, embodied generally in Swiss regiments distinct from the native troops of the country. They are the *condottieri* of the middle ages, serving for their pay, and without any other principle or attachment, real or assumed, or any pretext of higher motive for their service. In other services the rudest soldier, the most arrant scamp, the vagabond, the deserter from other regiments, lays the flattering unction to his soul, that destiny, folly, hard necessity, wildness of youth, love of distinction, of country, of honour—something, in short, connected with principle or fate—has led him into the military service. But these Swiss have no principle, real or imaginary, but pay. They engage generally for terms of four or six years, and receive a bounty of one napoleon for each year they engage for. This bounty is not paid to them in full upon enlistment, but a portion of it is placed to their credit in their *livret* or book, which every private has in foreign services, and is paid to them at the expiry of their engagements, to enable them to return home from the port of Genoa, to which those serving in Italy are sent free of expense, if they do not choose to re-engage for a new term of years. They receive much higher pay than the native troops. A subaltern in a Swiss regiment in the Neapolitan service has better pay than that of a captain in a Neapolitan regiment. The men receive four *gran* and bread, and the *élité*, or old soldiers who have re-enlisted, five gran per day, and their ration of eight ounces of meat costs but three gran. They are consequently well off as soldiers, are always in good quarters, and under their own Swiss officers; and both at Naples and Rome are undoubtedly fine, well-appointed troops. Scotland formerly furnished the same kind of condottieri to Holland, Sweden, and France; but the advance of industry and manufacture at home, the colonization of America, and the demand of England for labour from the poorer country, extinguished this kind of military service; nor was it at any time so devoid of all connection with principle or chivalrous motives, as the Swiss enlistments of the present day. The Scotch peasant enlisted under his clansman, or the son of his landlord, who, from attachment to the Stewart cause, or difference of religion, or from national prejudice, preferred foreign service to the British, even with inferior pay. The recruiting also for foreign service was unacknowledged and private. But the Swiss government

[1] *Almanach de Gotha for* 1856.

sanctions the demoralizing system, allows the recruiting publicly, and with the same protection and regulation as for a national army; and sells, for the benefit of a few aristocratic families, principally of Bern, who officer these mercenaries, the military services of her young men to support the most arbitrary governments in Europe. The Protestant republic of Bern furnishes one regiment entirely for the service of the king of Naples; and even in the Pope's body-guards there are Protestants from Bern and other Protestant cantons. No government can set principle at defiance with impunity. These men return to their little spots of land, devoid of religious habits or feelings, or attachment to any religious faith. This service keeps up through the whole population of Switzerland principles and conduct adverse to religious character. The men who thus enlist to pass their youth in the most vicious and bigoted cities in Europe, Naples and Rome, are not the refuse of their country, but the sons of respectable peasants, who are to return to their little heritages and marry, and settle as fathers of families.

Ottoman army.

At the period when the Ottomans first became formidable to Europe, they may be said to have composed one immense army. Every Osmanli was a soldier, and from the age of sixteen to sixty held himself at the disposal of the state; whilst all were animated with a martial fanaticism, which in fact constituted the main sinew of their strength. They were brave, ardent, enterprising; and if their services in the common cause (which they could not withhold as long as they were able to bear arms) remained unpaid, they were not unrequited. A third of the conquered land was distributed amongst them, and held on the tenure of military service; the peasantry cultivated the fields thus ceded to the soldiery, and paid the rents to their military landlords; and the holders of the *ziamets* and *timars*, or greater and lesser grants, received from the fund of conquest rewards proportioned to their services. But this system, although it placed a large numerical force at the disposal of the chief, was nevertheless attended with serious inconveniences. It created a sort of feudal militia, but was incompatible with the existence of a permanent force; it supplied means for a short expedition or campaign, but a continued series of operations was constantly liable to be paralyzed by the soldiers returning to their homes while these were still in progress. To obviate this evil, it was resolved to raise a body of mercenaries, whose services should be at all times available. Accordingly, Sultan Amurath, at the suggestion of his vizier, claimed as his right the fifth part of the Christian youth captured in Bulgaria, Albania, Servia, and Bosnia; who, being instructed in the law of the prophet, and inured to arms, formed a body of soldiers totally distinct from those liable to serve in virtue of their military holdings, and unconnected with the rest of the empire by the ties either of birth or of kindred. Such was the origin of the Janissaries. Organized into a regular force, at a time when the armies of Christian powers consisted of a disorderly militia, and uniting courage and enthusiasm with a species of discipline, and a blind obedience to the will of their commanders, this powerful body swept all before them, and spread far and wide the terror of the Ottoman arms. Nor did the splendour of their achievements suffer any eclipse as long as Christian captives could be obtained to fill the vacancies in their ranks. But when the Janissaries ceased to form a class distinct from the great mass of the nation—when they were allowed to marry and enrol their children—and when the *odas* or regiments became encumbered with men who preferred inglorious ease in the bosom of their families to the toils and dangers of the battle-field—they at the same time ceased to be formidable to their enemies; and, like the prætorian cohorts of ancient Rome, were dreaded only by their emperors. They could raise an insurrection in the capital, demand the head of an obnoxious vizier, and depose or murder an unpopular Sultan; but "the yellow-haired Giaours" had learned to despise them in the field; and, in their degeneracy, they seemed destined to accelerate the ruin of that empire which, in their better days, they had contributed so largely to extend and consolidate.

On this class of men, however, did the Porte, until recently, depend in a great measure for defence against its enemies; and although their inefficiency was daily becoming more apparent, and reform more necessary, every attempt to effect a change of system, and regenerate these Osmanli prætorians, had proved either abortive or disastrous. In vain did Selim try to remodel them, and restore discipline. The attempt cost him his life. In vain did Mahmoud, on his accession, manifest an intention to enforce the regulations of Suleiman the Magnificent. An insurrection was the consequence. During three days the streets of the capital ran with blood; and the Sultan, in order to save his own life, was obliged to command the execution of his brother. But Mahmoud was not of a disposition to be daunted by this failure, although it induced him to change his mode of proceeding. He now saw that nothing less than the complete destruction of the Janissaries would enable him to improve the condition of his empire by carrying through the reforms which he already meditated; and he waited patiently until he could strike the blow with a certainty of success. In 1826 the Janissaries, who perceived the storm gathering, again mutinied. But it was now too late. They found the Sultan prepared for them; and, in raising the cry of insurrection, they only gave the signal for their own destruction. The artillery-men and other troops, faithful to Mahmoud, surrounded them in the Atmeidan; they attempted to defend themselves, but without success; 20,000 perished in the conflict; and the Janissaries as a body were from that moment annihilated. This achievement, though accomplished at a terrible sacrifice of life, was in reality an act of humanity as well as of sound policy; and, viewed in its proper light, it reflects equal honour on the wisdom and firmness of the Sultan, who planned so judiciously, and executed so vigorously, a measure full of peril in itself, yet absolutely indispensable as a preliminary step to improvement of any kind.

The suppression of the corps of Janissaries having left Mahmoud at liberty to remodel his army conformably to the principles of European science and tactics, he hastened to supply the void occasioned by the destruction of the force to which the country had hitherto trusted for its defence; and orders were immediately issued directing the enrolment of a certain number of men in every province of the empire, excepting Albania, Bosnia, and the African states. But the Sultan experienced greater difficulty in raising new troops than he had probably anticipated; for, although the law which places the services of every Moslem at the disposal of the Sultan existed in full force, it applied only to a state of war; and on no previous occasion had such a system of enrolment been resorted to during time of peace—a circumstance which rendered it exceedingly obnoxious to the populace. Another obstacle to the speedy reconstruction of the army consisted in the necessity of excluding from the new corps all persons suspected of what may be called *Janissarism;* and as it had been customary for every Moslem, on attaining the age of manhood, to inscribe his name in some oda or regiment of Janissaries, the only method by which Mahmoud could hope to secure his troops from the contamination of that proscribed sect was by enrolling none but boys in his army. But the adoption of such a plan necessarily created a proportionate difficulty in filling the ranks; while, to add to the embarrassment of the Ottoman reformer, the new system had scarcely been twelve months in operation when Russia declared war against the Porte. That this was a politic proceeding on the part of the Muscovite government no one can doubt. Mahmoud was caught in the very act of transition from a bad system

Army.

to a better one; the regiments of the Ottoman army were still incomplete; and the unpopularity of the contest, with a dread of the Russian arms, acted as an additional check to enlistment, and thus aggravated the evils with which the Sultan had to contend. The new troops were, however, brought into action. They were as yet too ignorant of the advantages of discipline to benefit by the instructions they had received; their manœuvres served but to confuse them; the officers were superior to the men only in name, and the generals were equally destitute of talent; the interior organization of the army was lamentably defective; and the troops had but little confidence either in their officers or in themselves. Yet, with all these disadvantages, the first campaign terminated favourably for the Turks; and it cannot reasonably be doubted that the second one (that of 1829) would have had a similar result, if the Osmanlis had been commanded by a man possessed even of ordinary military talents and enterprise. The grand vizier was unquestionably a brave man; and unlike Yusuff Pasha, he was faithful as well as brave. But, with 40,000 regular troops, superior to any that the Porte had ever sent into the field, he allowed himself to be surprised at Kiulewtscha, or Kuleftscha, and, having lost more than the half of his force, was compelled to retire to Shumla with the remainder. The succeeding events of the campaign were the natural corollaries of this disastrous battle.[1] Turkey was compelled to a very humiliating peace at Adrianople. A manifest improvement after this took place in the Turkish army. In 1853 Omar Pasha, at the head of 150,000 men, defied the Russians on the banks of the Danube. The Sultan Medjid—the most enlightened Turk that ever sat upon the throne; devoting his attention to reforms in all branches of the state, even to the infraction of the ancient Mohammedan laws—endeavoured to raise the army above the influence to which it was exposed by the rapacity or the imbecility of pashas. His efforts succeeded to the extent of introducing a higher state of discipline, and inspiring the Osmanli soldier with a cordial devotion to the interests of the state.

The battles of Oltenitza and Giurgevo demonstrated the zeal and intrepidity of the troops in the field; and the defence of Silistria, and, subsequently, of Kars in Asia Minor, attested their valour and firmness, their patience and constancy behind the walls of a fortress.

The Ottoman army is composed of regular and irregular infantry and cavalry, a corps of artillery, and a regiment of bombardiers or miners. The *Assakiri Monsurei Mohamediyes*,[2] or regular infantry, are said to amount to 50,000 men, of whom 10,000 compose the imperial guard, quartered in and around Constantinople. They are recruited from the mass of the people without distinction; and although neither Mahmoud nor his successor, Abdul Mesjid, obliged the children of his nobility to enter into the service, yet, at the beginning of the present war with Russia in 1853, many enlisted voluntarily, and even some of the Ulemas, or expounders of the law, forsook their peaceful profession and enrolled themselves. The black and white subjects of the Sultan are alike received as soldiers; and in a single regiment may be seen every shade of "the human face divine," from the jet black complexion of the Ethiopian or Nubian, to the white-visaged inhabitant of Rumelia.[3] Once enrolled, a soldier is obliged to serve for life; but it frequently happens that discharges are granted. The regular troops are organized on the model of the French army, and are divided into corps d'armée, divisions, brigades, and regiments. The corps d'armee is commanded by a seraskier, the division by a pasha of three tails, the brigade by a pasha of two tails, the regiment by a miri-alaÿ or colonel, and the battalion by a bimbashee or chef-de-bataillon. A regiment consists of a regimental staff (including the miri-alaÿ or colonel, the caimacan miri-alaÿ or lieutenant-colonel, and the alaÿ-eminy or major) and three battalions, each composed of one bimbashee or chef-de-bataillon, one sagh-col-aghassy or adjutant-major, one sol-col-aghassy or adjutant, 8 yuzbashees or captains, 16 mulazims or lieutenants, 32 tchiaouches or serjeants, 48 on-bashees or corporals, and 720 men—making a total of 2484 officers and soldiers, exclusive of a drum-major, an imaum or chaplain, and a kiatip or clerk. The inveterate prejudices of the Moslemin against the employment of European officers in the service prevented Mahmoud from placing any foreigners in command of his troops, and these were disciplined, partly by officers who had served under Selim in the Nizam Djedid, partly by persons sent from the Egyptian army; but the recent war with Russia has compelled the Turk to yield to circumstances, and Abdul Mesjid, the reigning Sultan, has sanctioned the officering of a large force by Europeans, chiefly Englishmen. The Ottoman officers, taken from the same class of society with the common soldiers, differ from them in nothing but rank and name: in the Turkish army there is no one to look up to, no natural aristocracy created by superiority of condition and of knowledge: the same ignorance and the same prejudices pervade all ranks: and, having the benefit neither of example nor of models, their progress in discipline has been necessarily slow. The Turks seem to think that performing the manual and platoon exercises with tolerable precision, marching in companies instead of independently, and wearing a peculiar uniform, is sufficient to class them with disciplined troops. But in their anxiety to attain the end desired, they have overlooked some of the most essential means. The soldier, for example, is placed in the ranks before he knows how to march; and provided he goes through the manual and platoon exercises, it matters not whether his carriage be steady or the reverse. When in the ranks, the men talk and laugh without restraint, and even address themselves to their officers; whilst the latter, instead of checking, encourage these improprieties, by joining in or retorting the rude ribaldry of the troops. Field officers are, indeed, treated with the most obsequious respect by their inferiors; but the line which has been drawn between the privates and subaltern officers is by no means sufficiently distinct; and it is easy to perceive throughout, that the hand of a master is wanting to combine all the elements of discipline, which are now but imperfectly understood, and to impress upon the higher ranks the necessity of studying their profession, in order to qualify them for discharging the duties of command, as well as to ensure the respect and obedience of the troops.

The Turkish *cavalry* had so long been celebrated for its gallantry and enterprise, that the policy of remodelling it seems exceedingly questionable. This, however, has been attempted, though, as it appears, with very indifferent success. The only regular cavalry in the empire are mounted and equipped in the European fashion; but the horses are small

[1] Trant's *Narrative of a Journey through Greece* in 1830, p. 364, *et seq.* We take this opportunity of acknowledging our obligations to Captain Trant's work for a very considerable portion of the details respecting Sultan Mahmoud's military reforms. There are many points in regard to which it could have been wished that Captain Trant had been somewhat more specific; but on a subject where exact information was not easily attainable, military men ought to be grateful for what this respectable officer was able to collect concerning it.

[2] Literally, "victorious troops of Mohammed."

[3] "Ah!" said a Janissary to Captain Trant, while observing a body of troops marching past, "What kind of soldiers are these? You see every race and every colour on earth amongst them!" "Granted; but martial qualities are not necessarily connected with colour; and discipline, if rigorously enforced, will in time mould even these variegated elements into a fine and formidable army."

in size, ill-conditioned, and badly groomed;[1] and the men find so great difficulty in accommodating themselves to the European method of riding with long stirrups, that their seat is loose and ungraceful; and they are not unfrequently thrown from their saddles to their own infinite mortification. The scimitar, so effective in the hand of a Turk when mounted in the fashion of his country, has also been exchanged for the French light-dragoon sabre; a weapon so differently balanced from that which the Osmanlis have long been accustomed to handle, that they are not likely soon to acquire much dexterity in the use of it. These changes, in fact, seem the very wantonness of innovation; for whilst they have destroyed all that is national or characteristic in this description of force, they have substituted nothing effective in its stead; and it has been found in the present war that the Sultan sacrificed a superb light cavalry for wretched dragoons. His policy should have been, to leave to the Turks their national horsemanship and their national weapons, and to direct his attention exclusively to field tactics and manœuvres, in order to give unity and effect to those daring charges which they are so admirably fitted to execute effectively in their own way. Without firmness in their saddles or confidence in their weapons, the troops make a tolerable appearance on parade; but in the field they are unable to contend with the worst description of horse to which they may be opposed.

The *artillery* is of two kinds, viz., foot and horse. The topejees or foot artillery are at present 11,000 strong. Their new organization is of very recent date; they are now formed into distinct regiments, and quartered over the empire. The horse-artillery, though in a very inefficient state compared with ours, has made considerable progress in discipline. It is divided into regiments of four troops each; and every troop consists of one captain, three subalterns, 180 men, 180 horse, and 10 guns; thus making the total effective strength of a regiment 786 men, 720 horses, and 40 guns, which are commonly nine-pounders and five-and-a-half-inch howitzers. The officers are supplied with horses by the government; and the forage allowed to each horse is nine pounds of barley and twelve pounds of chopped straw *per diem*. The corps of bombardiers and miners amounts to about 3000 men; but they are still undisciplined, and as ignorant of the scientific as they are negligent of the practical part of their profession; their gun carriages, platforms, and ammunition waggons, being in a very inferior state. The education of artillery-officers has hitherto been much neglected; but a college has recently been established for their instruction in the theory and practice of gunnery; and a good many young Turks are sent to France for a military education.

The irregular army may be said to comprise the whole Mohammedan population of the Ottoman empire; since, as already stated, every Moslem, if required, is obliged to join the army during time of war. The irregular cavalry is raised by the Znaims and Timariots, who hold feudal grants from the Porte on tenure of military service. The irregular infantry is assembled by the pashas and inferior officers in the provinces. Eighty years ago, the irregular cavalry constituted by far the most formidable and effective force belonging to Turkey; but the country whence it was derived having been wrested from the Porte by Catherine II., her enemies now use it with great effect against her.[2] The Khans of the Crimea were most useful tributaries of the Porte, and were at all times ready to take the field with from 40,000 to 50,000 horse of the very best description, considered as irregular troops. Brave, hardy, accustomed to support fatigue and privation, inured to riding from their infancy, and obedient to their leaders, the Crim Tartars formed the main strength of the Turkish armies; and, superior to the Timariots, who had become enervated by peaceful habits, were prepared for all kinds of service, nay, even to encounter the best regular cavalry that could be brought against them. The loss of the Crimea, therefore, and of the enterprising troops it supplied, inflicted a severe injury on the military resources of Turkey. The irregular cavalry is now principally drawn from the Asiatic provinces; but as the Mohammedan population has much decreased, this force is consequently less numerous than formerly. The irregular infantry, called Seimens, is furnished by the pashas, ayans, mousselims, and voivodes; and, during the last war, some regiments so raised received pay from the Porte. The men were drawn from Rumelia and Asia; and it is not a little remarkable, that of those who distinguished themselves most in the field in 1828 and 1829, the majority had belonged to the proscribed corps of Janissaries.

The present strength of the whole Ottoman force, almost all of which is in the field, is, according to the most recent accounts, as follows:—

Regular active army	138,680
Reserve	138,680
Irregular troops	61,500
Auxiliary contingent	110,000
Total	448,860

The military establishments of Turkey have yet, in a great measure, to be created: but the Sultan is indefatigable in urging on improvement to the utmost extent of his crippled means. The only founderies for casting cannon are in Constantinople. They are three in number—one of two furnaces, attached to the military arsenal at Tophana; another, also of two furnaces, near the naval arsenal; and a third of one furnace at Hassquiou, the bombardier barracks. In one of these establishments sufficient metal can be melted to cast from five to seven guns at a time; but in all, the tools are of the coarsest description, and everything is effected by manual labour, without the aid of machinery. The workmen are Turks and Armenians; the superintendent an American. The military arsenal at Tophana contains a large stock of artillery of various calibres, and some of extraordinary length.[3] The field pieces are in tolerable order, but the guns have neither sights nor scales. Schools or colleges of medicine,[4] of the marine, of music, and of military instruction, have been for some years established at

[1] This may seem singular, considering the ideas generally entertained of Turkish horses: but, in the first place, these are very much exaggerated; and secondly, the government was obliged to purchase horses wherever they could be found—in Asia, Rumelia, and Wallachia. The best horses belong to the irregular cavalry.

[2] During the campaign against Russia in 1826, the Turks had generally bad information, frequently none at all, respecting the movements of the Russians; whilst clouds of Cossacks scoured the country in every direction, cut off the Ottoman *éclaireurs*, explored all the routes and even bye-paths, and conveyed to headquarters prompt intelligence of the slightest movement on the part of the enemy. It was this entire command of the communications which gave Diebitsch so great a superiority during the latter part of the campaign, and enabled him to surprise the vizier at Kiulewtscha, to mask the celebrated march by which he turned the barrier of the Hæmus, and to acquire for himself the well-merited distinction of Zabalkansky, or Passer of the Balkan. The troops sent to intercept him in the mountain gorges arrived too late, and Zabalkansky was thus enabled, with a handful of troops, to dictate peace in the ancient capital of the empire.

[3] Near the seraglio are several enormous guns carrying stone balls like those fired at our fleet when passing the Dardanelles in 1808. But cannon of this description can only be discharged with effect when the object passes their line of fire, as they are not mounted upon carriages, but built in a wall. Some of the guns at the Dardanelles carry balls 26½ inches in diameter.

[4] There was nothing in Turkey which stood more in need of reform than the healing or rather the killing art. With all their predestinarian prejudices, the Osmanlis place unbounded faith in the skill and knowledge of physicians; and although they have been at all times ready to acknowledge the superiority of Europeans in the science of medicine, they have nevertheless for the most part been

Constantinople. Between three and four hundred young men are instructed at the military school, which is under the superintendence of the chief bombardier, in mathematics and the principles of fortification and gunnery; and some few French works upon military subjects have been translated into Turkish for the benefit of the students. Sultan Mahmoud also established a kind of commissariat department, under the control of the Asker Naziry̆ or superintendent of the troops; and Turkey now boasts of good military hospitals under competent management. Great progress has been made in reforming the pay department, in which enormous abuses formerly prevailed; the troops and the Sultan having been alike plundered by the knaves intrusted with this important branch of the public service. But since the management of the finance, commissariat, and general organization of the army, has been vested in the Asker Naziry̆, conjointly with the seraskier and other high official persons, matters have been placed on a much better footing.

The barrack department in Turkey is extensive. Whichever way one turns the eye at Constantinople, it is almost sure to rest upon a great barrack. These buildings are numerous and imposing, if not in their architecture, at least in their size and spaciousness. Sultan Selim, when attempting for the first time to form a Turkish army disciplined in the European manner, erected several extensive buildings for the accommodation of the Nizam Djedid, or new troops; but when the Janissaries got the better of him, they knocked down most of these buildings. Sultan Mahmoud was the great barrack-builder. Abdul Medjid has added only one or two to the number. Taking into account the vast barracks of Mahmoud at Daoud-Pasha outside the city, the immense barracks in the Asiatic suburb of Scutari, and the barracks and commodious guard-houses on either side of the Bosporus, 100,000 men might be lodged here without much crowding. In the spring of 1848, several of these great barracks were entirely empty, and there were others that had but few inmates. More than one, which had cost Mahmoud immense sums in 1828, were already neglected, and showing symptoms of decadence. The artillery barracks just outside the Pera suburb, were erected by Sultan Selim, and upon plans and designs furnished by Count Sebastiani and General Andreossy. They are well situated; they are imposing in their extent, and seem to be in all respects well suited to their purpose. The entire barracks could comfortably hold from 3000 to 4000 men. They are exceedingly well ventilated. The distribution of the apartments or wards is excellent. In each long room there are two double rows of mats, each row accommodating about 55 men. The mattresses and bed-covers are stowed away in the middle of the room, in an open wooden screen which occupies very little space; they are neat and clean, and very well arranged. At night the mattresses are spread over the matting of the floor. Bedsteads are dispensed with, except in hospitals. But hardly any Turks think as yet of using bedsteads, or of setting apart rooms merely as bed-rooms. In the best houses they sleep on the broad divans, or spread their mattresses on the floor. In the morning the servants come in, and walk away with the beds; and then the room where you have slept becomes a drawing-room, or a dining-room, or both in one. During the day, bed and bedding are deposited in presses or cupboards. Mr Macfarlane, who visited Turkey three or four years since, writes—"The artillerymen's mattresses are at least as good as those we generally slept upon; as usual, the most slovenly feature was in the shoeing. In the corridor, at the door of every barrack-room, there was a multitudinous array of muddy, filthy boots and shoes, through which it was not always easy to steer one's way without tripping. The soldiers must not enter the rooms with their shoes or boots on. These are thrown off at the door: if the men have slippers they put them on; if they have not, they must walk on the soles of their socks. But the same rule obtains everywhere: there is no walking a hundred yards without being covered with mud in winter, and dust in summer; and then the Mussulmans, with almost the strictness of a religious observance, consider their carpets and mattings as things to be trodden only by clean slippers or bare feet. At the foot of the main staircase of every much-frequented Turkish house, we invariably found a confused heap of mud-boots, dirty boots, and shoes. It was so at Ali Pasha's. When the staircase happened to be a dark one, I never could help blundering among some such heaps. The effect was very disagreeable to other nerves besides the olfactory. A very little care and arrangement would obviate it; but it is *adet*, old custom.

"The officer in command at the artillery barracks—one of the many Achmet Pashas—was civil and rather communicative. He agreed that the whole appearance of the soldiers would be much improved if they were better shod, and would make use of brushes and a little blacking. Their present process of cleaning boot and shoes (when they clean them at all) is to rub them over with birch brooms, and then wash them in cold water. Shoe-leather neither washes nor *dries* well; and hence many bad colds and coughs. There was not a jacket nor a pair of trousers in barracks but sadly needed beating and brushing. The best of the artillerymen look dirty and negligent in their persons. A neat old English or Austrian soldier is far cleaner and more tidy in coming off a long and rough campaign, than these Turks, who are hardly ever moved from their barracks. Achmet Pasha treated us to pipes and coffee, and to the sight of some horse-artillery exercise and manœuvres. The guns were all brass; the carriages were all painted with a very light green paint, which had a bad and very mean effect. Neither guns nor carriages were kept clean. The harness was abominably dirty. The horses were all white or very light grays; they told us that they were bred in Rumelia, in the country up above Phillipopoli; I was much deceived if they were not all Transylvanian or Hungarian horses—they bore a very close family resemblance to a breed I had often admired in the Emperor of Austria's army. They were what we should consider under-sized for that service; but they were compact and strong, and not at all deficient in spirit; they were well broken into their work, were admirable in hand, and the artillery drivers drove them in good style. About a dozen light field-pieces were very well handled in an inclosed field in front of the barracks. It was by far the best specimen of military exercise we saw in Turkey: but the Pasha showed us only his very best men. The instructing officer was a German, who had been a serjeant of artillery in the Prussian service. A few young Turkish subalterns seemed both active and intelligent; but the superior officers were sitting down on stools, looking on, and smoking their tchibouques. The Mahmoud barracks over at Scutari, though wanting elevation, are truly magnificent in length and breadth, and in situation. Take them altogether, they are the finest barracks I ever saw in any country.

"Before the conflagration the barracks could lodge from 6000 to 7000 men. There were now in it two regiments of infantry, one regiment of artillery, and a few squadrons of cavalry. None of these men had been moved for very many months; during the winter they had hardly quitted their barracks. The cavalry were all lancers, and so in-

obliged to intrust the welfare of their bodies to empirical adventurers, whose knowledge had been acquired much in the same manner as that of the learned hakim Yacoob, so admirably described in "Anastasius." Recently the British government has sent out a gentleman who had much distinguished himself as professor of the Calcutta Medical College, to organize a similar college at Constantinople.

deed were all the horse-soldiers we saw of this new regular army. We heard of dragoons and of corps of heavy cavalry; but we never saw a single specimen of either. They had no horses in the country fit to mount a heavy regiment. The pasha sent one of his officers to conduct us over the barracks. Here, where there had certainly been no preparation or previous notice, there were some few signs of slovenliness and negligence; but, on the whole, one might fairly say the barracks were in excellent order. The stables, like all the Turkish stables I ever saw, were decidedly bad. They would have thrown an English or an Austrian dragoon into a passion. Soldiers who will not beat and brush their own jackets are not likely to bestow much pains on the coats of their horses; we never saw a trooper's horse look as if it were groomed. I believe these lancers of the imperial guard were entirely innocent of the use of curry-combs and brushes. What with the natural slovenliness of the men, and the rough and dirty appearance of the horses, a regiment of lancers when united presented but a shabby picture—a picture to excite derision on any parade or drill-ground in Christendom. Some of my Frank friends argued that this outward and visible show would not affect their fighting qualities. *J'en doute.* A good soldier is always a clean soldier; it is by cleanliness and the care of his groom, as well as by good food, that the trooper's horse really becomes a war-horse. The fellow who is so lazy that he will not clean his own boots is the very man to be negligent of more important duties. In an excellent, open, extensive drill-ground, offering the most glorious views of Constantinople, the Propontis, the islands, the Asiatic coast, and the snow-covered summits of Olympus, we saw some infantry being drilled by Turkish officers, who, for the most part, seemed very much to stand in need of drill themselves. It was slow and slovenly work, but conducted with great calmness and good-humour. The Sultan insists that there shall be no beating, no cruelty or harshness. There certainly was none *here;* nor did I ever see any at Constantinople, except once, when a hideous-looking Nubian officer was drilling some white Turkish recruits in the broad galata moat, and soundly thrashing the dull ones with a country riding-whip made of buffalo's hide. Part of a regiment which had fulfilled its term of service, but which was kept together, and very incorrectly called a *militia regiment,* marched across the drill-ground, and went to perform some light infantry movements on the gently sloping hills between the barracks and the grand cemetery of Scutari. These men were neater and cleaner than the infantry in the barracks, from whom they were distinguished by wearing the black cross-belts instead of white. They trod over the ground with a good light step, and their evolutions *en tirailleurs* were quick and good. But here again was the alloy, the canker of Turkish indolence: half of the officers, instead of marching at double-quick time over the hills with their men, remained behind on the drill-ground to gossip and smoke pipes with the officers there. Several of the smaller barracks we visited were deserving of all praise for order and cleanliness; this was particularly the case with those on the Bosporus at Arneoutkeni, Bebek, and Roumeli Hissar. To the spacious barracks in Constantinople Proper, which stand round the Seraskier's Tower, I was refused admittance. I believe that this refusal was owing to my having expressed a too eager wish to see the Seraskier's Prison, which stands within the same great inclosure of lofty walls. Externally the barracks looked neat and clean; they are very extensive, and admirably situated on the summit of one of the seven hills of Constantinople. Nearly every recent writer of travels in Turkey has dwelt upon the magnificence of the views from the top of the lofty tower of the Seraskeriat. We rather frequently passed the great inclosed square of the Seraskeriat; but although here were the headquarters of the army, we seldom saw the soldiers doing anything. But one afternoon, in the month of March, when the French revolution of 1848 had startled the Porte out of an easy slumber, we witnessed a great show of activity in the square. About 1500 men were exercising under the eye of a fat pasha (name unknown to us), and the great seraskier himself was looking on from a distant window, with a tchibouque in one hand and an eyeglass in the other. The majority of these men were not young recruits, but soldiers of some standing; yet their performance was rather loose and slovenly. When they formed in line, their line was far from being a right one; their formations into squares, hollow and solid, were but poor exhibitions. The men all looked slip-shod, and dreadfully dirty about the feet. With such shoes as they wear it is scarcely possible for them to march well; they might as well try it in their old unheeled paprashes. Many of the men would have been, in better hands, excellent materials for soldiers, being broad-chested and altogether well-made fellows.

"From this time exercise and military evolutions became rather frequent at the foot of the tower of the seraskier. At first the Turks chuckled over the troubles and disturbances of Christendom, but it was not long before they became apprehensive that these convulsions might bring about consequences and political changes that would be very fatal to their empire. If they rejoiced when the revolutionary principle reached Vienna, and when Kossuth and anarchy raised their heads in Hungary, it was but for a moment, and only out of the souvenir that the Austrians had been old enemies of the Osmanlis; and very soon they seemed to feel instinctively that, should any power be gained by the Czar, and any very serious injury be inflicted on the Austrian empire, the Ottoman empire would lose one of the best props upon which it leaned. Some of them talked big; but misgivings and fear were in their hearts. In their ignorance, or very insufficient information, they went on rather rapidly to the conclusion that it was all up with Austria; that Russia would soon have the entire command of the Danube, and would thence recommence war upon Turkey. The panic was, of course, increased when insurrection broke out in their Danubian principalities of Moldavia and Wallachia, and when Russia, claiming her indisputable right to interfere—a right recognized in successive treaties—began to march troops towards Jassy and Bucharest. In the months of May and June they had *exercises à feu* two or three times a-week at the Seraskeriat. If not decidedly bad, the firing was certainly not good. The Dadian's powder was detestable; the muskets were very bad, with the old flint locks. Hardly any of the regiments had percussion locks. The bursting of musket-barrels, with the catastrophes attendant thereon, were alarmingly frequent. Before long it may be very important that England should have a correct notion of the value of this army. I would not underrate it, but I feel confident that, alone, it could never stand in the field against the veteran troops of Russia; and that, unless Christian officers were put in the command (as we placed British officers over the Portuguese), they would be very inefficient and troublesome auxiliaries. A French officer—who had studied them well, who had lived long in the East, and who was also perfectly well acquainted with the Russian army, said that it was the most idle of dreams to fancy that this imperfectly disciplined army of Abdul Medjid could meet the troops of the Emperor Nicholas in the field. He considered that the degree of discipline to which they had attained did not compensate for the loss of the fanaticism and enthusiasm which animated their undisciplined predecessors; that they might make a stand, and fight pretty well behind stone walls; but that *en rase campagne* they would fall like wheat before the reaper's sickle, or go off like chaff before the wind. '*Ils n'ont point d'officialité;*' they have hardly any competent officers. As you ascend the scale of rank, instead of finding more science and experience, you usually find more

Army.

ignorance and inexperience. Generally the great pasha, placed by court intrigue at the head of an army, has never been a soldier, and is in military affairs about the most ignorant man in that army. He takes some officer into his favour, and relies for some time on his judgment and advice; then he changes, and takes another adviser; or, if his difficulties become at all complicated, he will seek advice of a dozen men, who may very probably entertain twelve different opinions and plans. Fancy, then, the jumble of every operation! In their intolerance or their pride, unless a Frank officer turn renegade, they will not allow him to exercise any command—they will not even permit him to wear a sword—he can be only a despised instructor, little more than a good drill-serjeant—he may or may not be well paid, but he cannot take real rank as an officer, or in fact be a part of the army. Here and there you may find a Polish, German, or Italian renegade, usually a deserter and a scoundrel. Hardly one of these fellows has ever been more than a non-commissioned officer in his own country; here they suddenly become captains, majors, colonels. These are the men the great pashas prefer. Low-born and low-bred, they can submit to Turkish arrogance, and to treatment which no gentleman can possibly tolerate. One may conceive how competent are these renegades to the conduct of an army in the field. Then, who would answer a single hour for the honour or common honesty of such a *canaille*? They have deserted their colours, they have deserted their religion; let Russia, or any other assailant of Turkey, tempt them with a good bribe, and they will desert the Sultan and sacrifice his troops."[1]

Since this was written, the Sultan has consented to the formation of a contingent, 20,000 strong, commissioned and officered by Englishmen; and there seems to be every probability of its proving a most efficient force. It consists of regulars and irregulars, the latter being for the most part Bashi-Bazouks from Asia Minor.

Greek army.

The reforms effected by Sultan Mahmoud in the military organization of the Turks rendered it expedient for the Greeks to attempt to form regular corps, in order to keep on a level with their enemy in point of discipline and tactics. Accordingly, on the 27th February 1827, the president ordered a military force to be organized in regiments (*chiliarchies*) of two battalions (*pentacosiarchies*), divided into five companies (*hecatoncharchies*) each; a regiment to consist of a colonel (*chiliarch*), two chefs-de-bataillon (*pentacosiarchs*), 10 captains (*hecatontarchs*), 20 lieutenants (*pentacontarchs*), 40 sub-lieutenants (*eikosi-pentarchs*), 80 serjeants (*dodecarchs*), 160 corporals (*pentarchs*), and 800 soldiers—in all 1122 men. Another decree ordains the formation of a battalion of artillery of six companies, with a suitable cortège of officers; and embodied in it a sort of provisional code of military law. Since Greece has become a monarchy under European protection, a small standing army has been organized, consisting of 8600 men and officers.

American armies.

The American armies require only a very cursory notice. That of the United States, exclusive of militia, amounts to little more than 10,000 men. It consists of eight regiments of infantry, four of artillery, one corps of engineers, two regiments of dragoons, one of horse fusiliers,[2] and a sort of general staff; and it is formed into three divisions, each under the command of a general officer. The republicans of the West have a great aversion to a standing army, and only maintain a sort of skeleton, to be filled up, in case of need, from the militia force. On 1st January 1854 the commissioned officers of the regular army amounted to 952, the non-commissioned officers and privates to 9377, being in all, 10,329 men. The militia in 1854 consisted of 758 general officers, 2407 general staff-officers, 13,787 field officers, &c., 49,337 company officers, and 2,054,740 non-commissioned officers, musicians, artificers, and privates, being 2,259,037 in all. The troops of the United States excel in bush-fighting; but they have neither organization nor discipline, and on any other soil than their own would be anything but formidable.—The Mexican army has been much reduced since its reorganization under the law passed on the 4th of November 1848, and in 1849 did not number more than 5200 rank and file in actual service.[3] In 1850 the actual armed force consisted of—infantry of the line, 3632 men; cavalry of the line, 1507; artillery, 658; active militia, 232; sappers and miners, 303; soldiers at military stations, 1282; national guard, 1295—total, 8909 men, with 520 officers. The black army of Hayti consists of the emperor's guard, with the infantry and artillery of the line. The guard, which ranks at the head of the army, consists of two regiments of infantry, one of grenadiers, and the other of chasseurs; and three regiments of cavalry, one of carabineers, one of grenadiers, and one of chasseurs. There are 33 regiments of infantry of two battalions each, and every battalion has six companies, viz., one of grenadiers 80 strong, one of chasseurs 50, and four of fusiliers 44 men each. Attached to this infantry, and distinct from the guard, are two regiments of dragoons of two squadrons, divided into two companies of 70 men each. The artillery consists of five regiments of two battalions, divided into nine companies of 50 men each, including officers. There is also an engineer corps, with 26 companies of 50 men each of artificers and pioneers. The whole of the Haytian force, therefore, including the staff and the president's guard, amounts to about 26,000 or 27,000 men.—We are not in possession of any accurate details respecting the composition and force of the various South American armies. The Brazilian is estimated at from 35,000 to 40,000 men, including militia; the Colombian or Venezuelan at from 15,000 to 20,000; the Peruvian at 20,000; and the Chilian at from 10,000 to 12,000 men of all arms. But these numbers are in a great measure conjectural. The military force of the Argentine republic is probably not greater than that of Chili or Venezuela; while that of Paraguay amounts to about 5000 regulars and 20,000 militia.

British army.

From time immemorial the inhabitants of the British Islands have been distinguished for a determined bravery, united with a degree of physical power, which belongs to the people of no other nation; and hence, as soldiers, they have never yet, when properly commanded, found their match in the field of battle. "L'Angleterre," says Count Turpin, in his commentaries on Montecuculi's *Mémoires*, "est elle peut-être la nation où la bravoure se soutient depuis le plus long temps." "Our nation," observes Dr Johnson, "may boast, beyond any other people in the world, of a kind of epidemic bravery, diffused equally through all its ranks; we can show a peasantry of heroes, and fill our armies with clowns whose courage may vie with that of the general." The valour of a Briton is innate. It is a national instinct, co-existent with and inseparable from the man himself, and requiring no artificial excitement to bring it into action; and it is as powerful at the present moment as it was in the chivalrous days of Cressy, Poictiers, and Agincourt. Hence, although the fortune of our arms may have varied, the character of the soldier has always remained the same; and at Waterloo as at Blenheim, and Ramilies, and Malplaquet, he established his superiority in all those high military qualities which render a nation invincible. But, from various causes, the reputation of the British army,

[3] Mayer's *Mexico*, vol. ii., ch. x.; Hartford, 1852.

which the campaigns of Marlborough had raised to the highest pitch, and which the various actions of the Seven Years War had gloriously sustained, began subsequently to decline; while the disastrous results of the American revolutionary war created an opinion, which succeeding events appeared to confirm, of its total unfitness for prosecuting a lengthened series of operations, or contending with any prospect of success against the armies of other nations, particularly those of the Continent. It was conceived to be little better than a body of marines, well qualified to cooperate with the navy in partial expeditions, or in making descents on the sea-coasts of any country with which Great Britain happened to be at war, but incapable of maintaining itself in the field, or of engaging in regular campaigns; and to say the truth, there were not wanting plausible reasons which might be alleged in support of such an opinion. For, as if they had been determined, not merely to countenance this impression, but really to render the army as inefficient and as utterly destitute of consistence and energy as it was generally believed to be, the British ministry persisted for a series of years in wasting its strength in paltry expeditions, or in effecting partial descents upon this or that country, instead of combining one great effort calculated to influence the general result of the contest. Yet, in 1795, the regular army, including the force under the Duke of York in North Holland, exhibited a total of 119,000 men, besides about 42,000 employed in the colonies, in Corsica, in Gibraltar and India; a force which, directed with skill and judgment, might have saved the country from many humiliations, prevented an enormous accumulation of debt, and accelerated the termination of a sanguinary and ruinous contest. The campaign of Egypt in 1801 showed, it is true, some small degree of energy, and, above all, afforded the army an opportunity of proving its undiminished excellence. But, unfortunately, on the renewal of the war in 1803, the old system was resorted to, and all the prejudices which had previously existed against the army were revived with tenfold force—prejudices which outlasted the first successes of the Peninsular campaigns, and were only at length overcome by an unexampled series of victories, obtained over the ablest general and the best troops of which France could boast.

"The French army," says Sir William Napier, "was undoubtedly very formidable from numbers, discipline, skill, and bravery; but, contrary to the general opinion, the British army was inferior to it in none of these points save the first; and in discipline it was superior, because a national army will always bear a sterner code than a mixed force will suffer. With the latter the military, not the moral crimes, can be punished. Men will submit to death for a breach of great regulations which they know by experience to be useful, but the constant restraints of petty though unwholesome rules they will escape from by desertion, or resist by mutiny, when the ties of custom and country are removed; for the disgrace of bad conduct attaches not to them, but to the nations under whose colours they serve. Great, indeed, is that genius that can keep men of different nations firm to their colours, and preserve a rigid discipline at the same time. Napoleon's military system was, from this cause, inferior to the British, which, if it be purely administered, combines the solidity of the Germans with the rapidity of the French, excluding the mechanical dulness of the one, and the dangerous vivacity of the other; yet, before the campaign in the Peninsula had proved its excellence in every branch of war, the English army was absurdly underrated in foreign countries, and absolutely despised in its own. It was reasonable to suppose that it did not possess that facility of moving in large bodies which long practice had given to the French; but the individual soldier was (and is still) most falsely stigmatized as deficient in intelligence and activity, the officers ridiculed, and the idea that a British could cope with a French army, even for a single campaign, considered chimerical. The English are a people very subject to receive and to cherish false impressions. Proud of their credulity, as if it were a virtue, the majority will adopt any fallacy, and cling to it with a tenacity proportioned to its grossness. Thus an ignorant contempt for the British soldiery had been long entertained before the ill success of the expeditions in 1794 and 1799 appeared to justify the general prejudice. The true cause of those failures was not traced, and the excellent discipline afterwards introduced and perfected by the Duke of York was despised. England, both at home and abroad, was, in 1808, scorned as a military power, when she possessed, without a frontier to swallow up large armies in expensive fortresses, at least two hundred thousand [1] of the best equipped and best disciplined soldiers in the universe, together with an immense recruiting establishment, and through the medium of the militia, the power of drawing upon the population without limit. It is true, that of this number many were necessarily employed in the defence of the colonies; but enough remained to compose a disposable force greater than that with which Napoleon won the battle of Austerlitz, and double that with which he conquered Italy. In all the materials of war, the superior ingenuity and skill of the English mechanics were visible; and that intellectual power that distinguishes Great Britain amongst the nations, in science, arts, and literature, was not wanting to her generals in the hour of danger."[2]

It is almost needless to add how conspicuously this brave and unequalled army disproved the calumnious prognostications of its contemners and revilers; how gloriously it established, in seven campaigns and more than twenty pitched battles, its superiority over the veterans of France, crowned with the laurels of a hundred victories, and accounted invincible till called to contend with the men of our soil. Let us now direct our attention to its composition and organization.

By the constitution of this country, the Queen is the supreme head and captain-general of the army, which can receive no orders except such as emanate from her, and is bound to obey all her orders, unless at variance with the fundamental laws of the land, in which case submission to her authority would be declared rebellion against the constitution of the state and the nation at large. To her belongs the power of declaring war and concluding peace, of granting subsidies to her allies and indemnities to her enemies; but no treaty is valid or binding unless it be signed by a responsible minister; and without the authority of parliament the Queen cannot touch a sixpence of her subjects' money for this or any other purpose. Further, it is expressly declared in the bill of rights, and annually repeated in the preamble to the Mutiny Act, which forms the martial law of the British army, "that the raising or keeping a standing army in time of peace, unless it be with the consent of parliament, *is against law*;" in other words no military force can be raised or maintained in this country, except with the consent of the three estates composing the legislature, by which, in their collective capacity, the sovereign power of the state

[1] At the period in question the British army consisted of 30,000 cavalry, 6000 foot-guards, 170,000 infantry of the line, and 14,000 artillery; in all 220,000 men. Of these between 50,000 and 60,000 were employed in the colonies and in India; but the remainder were disposable, because from 80,000 to 100,000 militia, differing from the regular troops in nothing but the name, were sufficient for the home duties. If to this force we add 30,000 marines, the military power of Great Britain, at the time referred to, must have exceeded 400,000 men, exclusive of local militia and volunteers.

[2] *History of the War in the Peninsula and in the South of France, from the year* 1807 *to the year* 1814. By W. F. P. Napier, C.B., Lieutenant-Colonel, H. P., 43d Regiment.

is exercised. But in regard to the existing army, all measures and all acts deemed necessary for its regulation, direction, and employment, are decided upon by the Queen in council; and it is the duty of the commander-in-chief of the forces for the time being to direct the execution of such measures or acts, in all those operations which are executed within the United Kingdom, as well as to superintend the organization, instruction, and discipline of the troops belonging to the different branches of the service. A secretary of state is specially charged with the administration of the war department in all its branches. He is the organ of communication between government and the army on the one hand, and between the army and the government on the other; and he acts as a check upon the commander-in-chief, while he is in turn restrained by his responsibility to parliament, to the country, and to the laws.

In the year 1795 a secretary of state for the war department was created, and in the year 1801 the colonial correspondence was transferred to the office. In the first instance, and during the whole course of the war, the principal business of the colonial department was to exercise a general control over all the military departments, the secretary-at-war, the ordnance, and the commander-in-chief; it was one head which directed all their operations to one common end; and as long as the secretary of state made this his principal duty, which was really and substantially the war department, that arrangement was good. The secretary-at-war was then, in point of fact, a sort of subordinate to the secretary of state for the war department. But at the end of the war, the mere military business diminished in importance; and, on the other hand, the civil business of the colonial office was rapidly increased in consequence, because it was found that during the war attention was very much turned away from the civil affairs of the colonies, and that everything yielded to the superior importance of military business. The result of that change after the peace was, that gradually the secretary of state for the war and colonial departments came to exercise less and less control over any details of military arrangements, and his attention came to be more and more occupied in the civil affairs of the colonies. As the extent of correspondence increased, that augmented; and the effect was that for 30 years the military affairs of the country were transacted by three or four different departments, and virtually without any one effective head to direct their measures to one common end. The war with Russia, which broke out in 1854, demonstrated the sad results of this system—so fruitful of confusion and irresponsibility—and the duties of secretary of state for war and the colonies were accordingly separated, the office of secretary-at-war abolished, and the control of military affairs placed entirely in the hands of a secretary of state for war only. This concentration of power and authority was followed by the abolition of the Ordnance and Medical Boards, a complete remodelling of the whole of the war department, and the introduction of a spirit of improvement which is producing the best re-

The departments exclusively military are those of the adjutant-general and the quartermaster-general.

The adjutant-general's department consists of the adjutant-general himself, the deputy-adjutant-general, the assistant-adjutant-general, and the deputy-assistant-adjutant-general, with a number of clerks, &c. The adjutant-general is named directly by the sovereign, on the recommendation of the commander-in-chief, and has the rank of lieutenant-general, though for the most part only a major-general. The deputy-adjutant-general is also appointed by Her Majesty; but the secondary offices of the department are filled by persons nominated by the adjutant-general himself. This officer may be considered as the director of the *personnel* of the British army. Everything relating to the effective or non-effective state of the troops; to formation, instruction, and discipline; to the direction and inspection of the clothing and accoutrements of the army; to recruitment, leaves of absence, or bounties to soldiers; to the employment of officers of the staff; and to ordinary or extraordinary and official returns relative to these different matters, whether required by Her Majesty, by the ministry, by the secretary-for-war, or by parliament, falls within the province of the department over which the adjutant-general presides. He is the regular channel through which commanders of corps communicate with the commander-in-chief; and all orders, special instructions, and general regulations issued by the commander-in-chief, relative to the organization, discipline, or instruction of the army, are prepared, addressed to the commanders of corps, and published by the adjutant-general, conformably to the direction of the commander-in-chief of the forces, acting in the name and on behalf of Her Majesty. The troops stationed in Scotland, however, instead of communicating directly with the adjutant-general's office in London, address themselves to the deputy-adjutant-general who resides at Edinburgh; and Ireland has also a deputy-adjutant-general resident in Dublin. It is also the duty of the adjutant-general to prepare, weekly, for the commander-in-chief and the Queen, returns of the troops stationed in Great Britain and Ireland; and, monthly, for the commander-in-chief, the minister-for-war, and the Queen, a general statement of all the forces both at home and abroad.[1]

The quartermaster-general holds the same rank, and is appointed in the same manner as the adjutant-general. His principal duties are to prescribe routes and marches, to regulate the embarkation and disembarkation of troops, to provide quarters for them, to mark out ground proper for encampment, to execute military surveys, and to prepare plans and arrange dispositions for the defence of a territory, whether such defence is to be operated by the troops alone or by means of field-works. Every British army on service has a quartermaster-general, with assistants, who perform functions altogether analogous to those which are discharged in the department of quartermaster-general of the British forces; and it is admitted on all hands that, during the Peninsular campaigns, this branch of service was, under the very able direction of Sir George Murray, carried to a high degree of perfection. Whenever the army, established for the time in any position whatever, had to move in advance and in a given direction, all the officers of the quartermaster-general's staff, charged with the reconnaissances, immediately set out and spread themselves over the ground, each individual taking the direction indicated to him, and pushing his reconnaissance to the extent of a day's march of the army. About five in the afternoon these officers returned to head-quarters; and by combining their different partial sketches, a general plan was prepared, according to which the quartermaster-general and the commander-in-chief traced the routes to be followed, and the positions to be taken up, by the troops who were to march on the morrow. This was the duty of every day while the army was in motion; and no better evidence can be produced of the ability with which it was performed than the circumstance that, during the whole of the Peninsular campaigns, the army never once took up a position in which it could be assailed by the enemy, however superior in numbers, with the remotest chance of success. Attached to the office of quartermaster-general of the forces is a Topographical Department, with a depôt of maps, plans, and military memoirs,

[1] Dupin, *Force Militaire de la Grande Bretagne*, I. ii., p. 54.

and a library containing the best military works that have been published in different countries.[1]

The barrack department is a numerous one, consisting of barrack-masters, store-keepers, hospital store-keepers, barrack-sergeants, and clerks. Their principal duty is to take care of the barracks for the reception of the troops; and generally see that the troops are properly accommodated, both as to room and otherwise. There are 118 barracks in Great Britain, of which 102 are permanent, and 16 temporary. In Ireland there are 109 barracks, of which 98 are permanent; and in the colonies there are 367 barracks. The number of persons which can be thus accommodated is 150,728 non-commissioned officers and men, and 6218 officers. A report recently sent in to government by a commission nominated to inspect the state of the barrack department has recommended extensive and important changes in the construction and distribution of barrack quarters.

The commissariat department consists of a director of commissariat attached to the War Office, a commissary-general, deputy-commissaries-general, and assistant and deputy-assistant commissaries, all of whom are employed in the colonies, the Mediterranean stations, and on field service.

Their duties consist in supplying provisions and forage to the troops; and in providing the materials of the medical department of the service. Every army on active service has its own commissariat, under the orders of a commissary-general, who is responsible, in the first instance, to the general-in-chief for the regular supply of the troops under his command. In Portugal and Spain, the provisioning of the army was effected by commissaries stationed at different places, or attached to brigades, and paid from funds supplied by the commissary-general of the army, consisting partly in cash and partly in bills or debentures on the English government. Immense abuses appeared to have prevailed in the commissariat department during the early part of the Peninsular campaigns. This is evident from the repeated orders of the day issued by the Duke of Wellington against malversations on the part of subordinates in this department; and not less so from the fact, that notwithstanding all the care and vigilance exercised by his Grace, many of these functionaries managed to realize fortunes.

The medical department of the army is under the superintendence of a director-general, who is on the establishment of the War Office; and a large staff of medical officers, including inspectors and deputy-inspectors general of hospitals, surgeons and assistant-surgeons, is attached to the army. Exclusive of these are a body of purveyors who provide the medical comforts necessary for the troops.

To the chaplain-general of the army is entrusted the providing for the spiritual wants of the soldiers, while the military schools are under the superintendence of an inspector-general; the regimental and garrison schoolmasters being trained chiefly at the military asylum in Chelsea.

A board of military education was constituted in 1857, to conduct the examination of candidates for commissions in the army.

The paymaster-general is the head of the army pay-office, whence the issues for the payment of every description of military service are made. This office consists of the paymaster-general himself, a deputy, a staff of clerks, and other subordinates; and there are several deputy-paymasters abroad subordinate to the general department at home. The paymaster-general has no active control over the expenditure of the public money. His duty is merely to make payments ministerially, and without discretion, in pursuance of the warrants directed to him by the secretary-for-war, the treasury, or both, as the case may be; or in honour of the drafts of the deputy-paymasters abroad, for the ordinary services of the army. The pay-office must therefore be looked upon as an office of account merely, and as affecting the public expenditure only in as far as it performs the duties of an office of accounts with regularity and expedition. The materials and documents, which compose a considerable part of the accounts of the paymaster-general, originate with persons over whose conduct he exercises no manner of control. Indeed, there is a regular succession in preparing them, from the regimental paymaster to the agent, and from the agent to the secretary-for-war, who finally delivers them at the pay-office. Different classes of accounts and documents are delivered in at certain periods prescribed by the pay-office act. But large balances of the public money are not now, as formerly, allowed to remain in the hands of the paymaster-general, or at his credit at the bank; nor can he derive any profit from the custody of the public money, the balances being confined within the narrowest possible limits. The establishment of a regiment, with the royal regulations and warrants, is in fact the instrument which regulates the pay of the army, and is consequently the basis of all the documents which enter or go out of the pay-office under that head of the service.

The department which comprehends the artillery and engineers is administered no longer by a board of ordnance, but is placed under the secretary of state for the war department. Under him are an inspector-general of fortifications, directors-general of the artillery, of stores, of clothing, and of contracts. And each department has a separate head acting under the directors-general, and these are called superintendents. Thus there are superintendents of royal gun factories, of royal carriage factories, of royal laboratories, of the small-arms factory, and of the royal factory of gunpowder. The sums voted for the support of this department proceed on estimates of the ordinary and extraordinary service, and of services unprovided for. So much for the military departments. Let us now attend to the composition of the army itself.

The British army consists at present (1858) of 10,555 cavalry and 119,580 infantry; but of this force, 8217 cavalry and 84,522 infantry are employed in the East India Company's territories. This force is altogether exclusive of the artillery and engineers, &c.

The *Cavalry* on home service consists of the 1st and 2d regiments of life-guards, and the royal regiment of horse-guards (blue), with 25 other regiments of dragoon-guards and dragoons; namely, 7 of dragoon-guards, 3 of dragoons, and 15 of light dragoons, including lancers and hussars, amounting to 9241 rank and file; or, including the regiments of life-guards, 10,555 rank and file. In this enumeration, however, the royal horse artillery, the military train, and the Cape corps of mounted riflemen are not included. The 1st regiment of dragoon-guards consists usually of 438 rank and file and 361 horses; but the remaining regiments of the cavalry of the line at home have only 328 rank and file and 271 horses each; those in the field are from 639 to 674 strong. The officers and non-commissioned officers of a regiment of life-guards, on its present establishment, amount to 85; of a regiment of the cavalry of the line, to between 60 and 70. Thus: 1 colonel, 2 lieutenant-colonels, 2 majors, 8 captains, 8 lieutenants, 8 cornets, 1 paymaster, 1 adjutant, 1 quartermaster, 1 surgeon, 1 assistant-surgeon, and 1 veterinary surgeon; or 35 officers in all, besides sergeants and trumpeters. And the same relative proportion obtains, whatever be the foot-

[1] Dupin, *Force Militaire de la Grande Bretagne*, I. ii., p. 59.

Army. ing, in point of effective force, on which the regiment is placed.

Since the peace of 1815 various changes have been made in the arms and equipments of our cavalry. In the first place, armour was given to the life-guards immediately after they had proved its total inefficiency in the field of battle, and torn the laurels of Waterloo from the redoubted cuirassiers of France. That armour must prove a decided impediment to the efficacy of a dragoon on service, is what no one can for a moment doubt. Its weight,[1] the constant cleaning which it requires, the pain which its inflexibility must occasion under fatigue, and the obstacles it opposes to the free and full action of the muscular powers of the human body, greatly detract from its advantages. These, moreover, have been overrated; and we are much mistaken if it will not one day be shown that the life-guards, encumbered with the cuirasses, are immeasurably less formidable than they were when their natural strength, weight, and activity had full freedom of action allowed them. In the next place, four of our regiments of light horse have been converted into lancers. We agree in opinion with Montecuculi, that the lance "est la reine des armes pour la cavalerie;" and we also think, with Major Beamish, that lancers should constitute the standard cavalry of England. But we do not the less object to the particular kind of lance introduced into our service, and the description of cavalry to whom it has been assigned. No nation possesses such materials as Britain for the formation of redoubtable lancers; no nation has the command of such means of bringing them to perfection; and if solid squares of infantry are ever to be penetrated by cavalry, it must be performed by cavalry armed with the lance.' But this will never be achieved by such a weapon as that at present in use. It must be effected by a lance of sufficient length to overcome the infantry bayonet, which, thus opposed, would no longer be formidable; and this lance must be put into the hands of our heavy cavalry, particularly the household troops, which, thus armed, would be able to contend on equal terms with the best infantry in the world, and would unquestionably be capable of penetrating its closest formation.

The British *Infantry* is composed of 3 regiments of guards,—viz., the 1st or grenadier regiment, the Coldstream regiment, and the 3d or Scots fusilier regiment, amounting together to 7600 rank and file; of 100 regiments of the line, consisting each of 1200 rank and file; of 1 rifle regiment (the 60th foot) and the rifle brigade, 2 battalions each; of 3 West India regiments; the field-train, 3 Newfoundland and 3 royal veteran companies, the Gold Coast corps, the Ceylon rifle regiment, the Malta fencibles, the Canadian rifle regiment, the St Helena regiment, and the Cape corps of mounted riflemen. The regiments of infantry of the line are commanded each by a lieutenant-colonel. With regard to the colonelcy of a regiment, it is in a great measure a sinecure, and is bestowed on old general officers; but a colonel is not debarred commanding a regiment in the field.

The ordinary staff of a battalion consists of 1 lieutenant-colonel, 2 majors, 10 captains, 12 lieutenants, 8 ensigns, 1 paymaster, 1 adjutant, 1 quartermaster, and 1 surgeon with 2 assistants—in all 39 officers. The petty staff is composed of a sergeant-major, a quartermaster-sergeant, a paymaster-sergeant, an armourer-sergeant, a schoolmaster-sergeant, 10 colour-sergeants, 30 sergeants, a drum-major, and 21 drummers—in all 106 men. In the regiments on field service the proportion is augmented.

The force serving in India previous to the mutiny in 1857, consisted of 2 regiments of light dragoons, and 21 battalions of infantry, or, including supernumeraries and others, 29,749 men and officers. At present (1858) the force numbers 92.739 men. Army.

The *Royal Artillery* forms only one corps, which is absurdly denominated a regiment, since, in the time of war, it is increased to more than 24,000 men. A general officer, with the title of adjutant-general, performs the functions of head of the artillery staff, but is in no way dependent upon the adjutant-general of the British forces. The office of the deputy-adjutant-general of artillery is at Woolwich, which may be considered the head-quarters of the ordnance. The royal artillery corps consists of the brigade of horse-artillery, and of the artillery serving on foot. The horse-artillery is subdivided into companies called troops. It is under the orders of 1 colonel-commandant, 2 colonels, *en second*, 4 lieutenant-colonels; while each troop is commanded by a captain of the first rank, a captain of the second, and 3 lieutenants. The foot artillery is divided into companies, under the orders of 12 colonels-commandant, 24 colonels, 36 lieutenant-colonels, 1 adjutant, 1 quartermaster, and a surgeon, with two assistants in time of war, and one during peace. In the year 1792 there were 4 battalions of foot artillery, consisting of 820 men each, with 1 battalion of invalids containing 483 men—making 3707 men in all. In 1814 there were 16,157 artillerymen, forming 11 battalions of 1459 men each. The rocket corps is attached to and forms part of the artillery; and the same holds true of the royal artificers, the field train, and the artillery drivers.[2]

In the war which preceded the peace of Amiens, and even in the early campaigns in Portugal, the *Engineer* department was in a very ineffective condition; particularly from the want of the necessary means of transport, and partly also from a deficiency both in the number and quality of military artificers. In order to remedy these inconveniences, the Duke of Wellington, in 1814, caused a brigade of engineers, consisting of a company of sappers and miners, with horses, cars, and drivers, to be attached to each division of the army, and to be regularly trained and exercised in field duties, as well as in those which might be required of them in sieges.

A captain and a certain number of subalterns were specially attached to each brigade, and were held responsible for the effective condition both of the men and the horses.

Thus the remainder of the engineers, free from any embarrassments relative to the *matériel* and *personnel* of that department of the service, were enabled to give their undivided attention to important military operations, and to contribute, in a most essential manner, towards the success of the succeeding campaigns. Five companies of sappers and miners also served with the pontoon train, which consisted of 80 pontoons, besides forges, waggons, &c., drawn by about 800 horses; the whole under the orders of a major of the brigade of engineers. After the peace great attention was paid both to the instruction and organization of this important branch of the service, which, since the war with Russia, and in many important civil duties connected with the survey of England and Scotland, and other public works. has been found on a very different footing, in point of efficiency, from that on which it stood during the greater part of the Peninsular campaigns. Experience taught important lessons, which have been suitably and effectually improved.

[1] The largest-sized cuirass worn by the life-guards weighs about 12 pounds. These cuirasses are as ugly as they are weighty, and give to the really fine men who are compelled to wear them an appearance of being *hump-backed*. The men do not regard them as defensive. They prefer such cover as the dexterous use of the sword can give them.

[2] Dupin, *Force Militaire de la Grande Bretagne*, I. v., c. 4, p. 196.

The portion of the British army presently serving in India amounts, as we have already seen, to about 92,739 men. It is paid by the East India Company, the officers receiving the same liberal allowances as they grant to those of their own service. Of late, the staff appointments of the Indian army, hitherto monopolized by the East India officers, have been, in a measure, thrown open to the royal officers, the only conditions of their eligibility being their acquaintance with one or more of the languages of the country.

In addition to the regular force, a militia is enrolled in England, numbering 80,000 men, divided into 85 regiments. The nucleus of an Irish and a Scotch militia is likewise preserved—the staff of no less than 54 regiments being constantly entertained; 15 of the regiments are Scotch, the residue Irish. Almost all of these regiments have been embodied, and some of them mobilized by act of parliament, which admits of their being sent to the Mediterranean. In the Channel Islands, also, are 10 regiments of militia infantry, and 3 of artillery; and in all the dockyards of England (Portsmouth, Devonport, Sheerness, Chatham, Woolwich, Deptford, Pembroke, &c.) the artificers and labourers are formed into brigades, properly commanded, equipped, and drilled. Thirty-five yeomanry corps, the honourable artillery company, which has its head-quarters in the precincts of the city of London, and the enrolled out-pensioners of Chelsea Hospital, complete the defensive force of the United Kingdom. The militia, always regarded as the nursery of the line, has contributed large numbers of disciplined men to the ranks of the regulars; and by way of encouragement to the militia officers to induce their men to volunteer, the government authorizes the commander-in-chief to confer line commissions on any militia subaltern who can bring 75 soldiers with him.

Down to the period of the late revolt there was an army belonging to the East India Company consisting of no fewer than 250,000 men, chiefly natives of the country, who were for the most part trained and clothed after the fashion of the British army. First enrolled in the days of Clive and Laurence, one hundred years ago, the sepoys have till lately proved "faithful to their salt," exhibiting considerable courage and endurance. In every corner of the continent of India—in Burmah, China, Afghanistan, the shores of Persia and Arabia, in Egypt, and even at Mauritius, in the presence of French disciplined troops—the sepoys distinguished themselves alike by their bravery, their fidelity, and discipline. And the result has been the entire subjugation of the country from Cape Comorin to the Himalaya chain—from Nepaul to the Arabian Sea. But it is due to the interests of truth to add, that the example of the British regiments has been of the greatest moment in the accomplishment of these mighty ends. Sir William Nott, who commanded a division of the army which invaded Afghanistan, and Sir David Ochterlony, who conquered the Nepaulese, had the most profound confidence in the sepoy. This confidence, which had become very common, has been destroyed by the late mutiny; and for the future the defence of our Indian empire must devolve on British troops.

The late army of the East India Company, before its disorganization, consisted of 5 brigades of horse artillery, or 17 European and 5 native troops; 18 battalions of foot artillery, or 24 European and 18 native companies; 22 regiments of regular native cavalry; 6 regiments of European infantry; 155 regiments of regular native infantry; 23 regiments of irregular native cavalry; 30 regiments of irregular native infantry; 5 contingent brigades of all arms, and a native legion. These troops were officered by Europeans holding commissions from the Crown and the East India Company, and expressly educated for the service. The staff, and all officers in the ordnance, commissariat, military account, survey, and pay departments, are commissioned officers in the service. The pay and Indian allowances are upon a liberal scale; and handsome pensions for life are granted to all classes after a stipulated period of service. Commissions in the East India service are not obtained by purchase, or through the gift of the British commander-in-chief. The patronage is vested entirely in the Court of Directors and the president of the Board of Commissioners for the affairs of India. Each member has a certain number of cadetships annually placed at his disposal, and these he must give away according to his discretion. Cadetships are not saleable. The law punishes with severity any trafficking in such commissions. Yet the practice of subscribing a sum of money in a regiment to induce a senior officer to retire is common, and receives the tacit sanction of the Court of Directors.

An admirable practice prevails among the officers of the Indian army of subscribing a small portion of their pay every month for the maintenance of two funds, one of which affords assistance to officers who may be obliged to proceed to England for the recovery of their health, and adds to the pension of retiring officers and their widows; while the other maintains destitute orphans.

The condition of the British soldier has been amazingly improved of late years, producing a decidedly favourable effect upon his *morale*, and creating a popularity for the service which it did not enjoy previous to 1830. The practice of employing the agency of fear as a stimulus to good conduct, has been superseded by the wholesome policy of encouraging merit by offering rewards for continued steadiness. The bounty on enlistment is no longer saddled with deductions for necessaries. Corporal punishment has been all but abolished—50 lashes now constituting the acmé of punishment. Good conduct, externally honoured by medals and badges, is also recompensed by a progressive increase to a soldier's daily pay; the sum of L.4000 is annually appropriated to annuities varying from L.10 to L.20, for which all non-commissioned officers of a certain amount of service are eligible; schools have been established, under the auspices of young men especially trained to the duty of teaching; libraries are formed in all the great barracks; medals have been freely granted for good service in the Peninsula, India, Egypt, the Crimea, &c.; provision is made for enabling a certain number of married soldiers to reside away from the barracks, and savings banks offer to the soldiery both the temptation to save and the means of securing their property. Great and important changes have of late years taken place in the arms and equipment of the soldiers; and long marches are consequently executed with greater facility. The construction of the knapsack, and the method of attaching it to the person, have been much improved, and even at this moment further amendments are discussed. The old musket—which seldom carried a ball above 180 yards, and was so irregular in its progress to the object aimed at, that the proportion of the enemy killed to the number of bullets propelled was 1 in 1000—has been superseded by firelocks of an improved construction, which will carry a ball 800 yards.

Formerly no display of remarkable valour in the field ensured to the private soldier a mark of royal approbation—promotion to the rank of non-commissioned officer was perhaps the only token he received that he had earned the approval of his commanding officer. By a recent warrant a new order has been created—the "Order of Valour," having for its decoration a bronze cross—the "Victoria Cross." Every soldier, of whatever rank, may possess this cross, with an annual stipend, if he has exhibited personal gallantry in the presence of the enemy. An Order of Merit—applicable to general deserving—is, however, still

a desideratum. Even in time of peace the heroism of the soldier is often called into play; and it is right that his devotion should be duly recognised. In cases of shipwreck, conflagrations, and civil outbreaks, when the discipline and patience of the soldier are severely taxed, a distinction like to that of the French Legion of Honour might fairly be awarded. It is bad policy to proclaim that the more active virtues developed in war are alone worthy of a decoration.

The character of the British army has been earned in battle and attested by victory. Wherever it has been even tolerably led it has conquered; nor is there any army in the world which has sustained so few serious reverses. The elements of which it is composed are such as, if fairly developed in action, must, on anything like equal terms, insure victory: for not only are the soldiers more robust, and possessed of greater physical power (or, as it is technically called, *bottom*), than those of any other nation, but they are also distinguished by an unflinching, indomitable courage, which may be safely reckoned upon at all times and in all circumstances; which it is often difficult to restrain, but never necessary to excite; and which always rises to a pitch of sublime elevation at the prospect of the charge and the close combat. They are the only troops in the world who look with indifference on naked points, and who are constantly impelled by a powerful instinct to close with their enemy; who maintain the distant battle with unyielding steadfastness, yet rejoice when the moment arrives that is to rest the issue of the conflict on the bayonet's point, and a struggle hand to hand with the enemy. Hence their fire is close, steady, and destructive; their charge, where it can be given, irresistible. "Les troupes Anglaises," says General Jomini, "se distinguent par leur bonne discipline et leur sang-froid; le soldat s'y enrôle pour la vie [this is a mistake; soldiers may enlist for ten years], ce qui est bien extraordinaire chez un peuple si jaloux de sa liberté, mais ce qui ne surprend pas moins, c'est qu'il est docile et soumis: ces qualités essentielles qui constituent une armée solide, sont peut-être préférables à une valeur brillante mais passagère. Les unes sont permanentes; l'autre, justifiant le proverbe Espagnol, dépend de tel jour et de telle circonstance. La résignation et la discipline unies au courage froid, ont des résultats invariables et sûrs; elles produisent l'ensemble sans lequel il n'est point de véritable force."[1] M. Dupin, in that part of his able work in which he treats of the military force of Great Britain, delivers an opinion somewhat similar to that expressed by Jomini, though shaded by certain qualifications and abatements.

But we need hardly quote foreign authors to demonstrate what the British soldier is when well commanded. The victories recently achieved in the Crimea, and the steady endurance of heart-rending sufferings during the long siege of Sevastopol, have proved to the world that he has in nothing changed, since, by his valour, perseverance, and discipline, he contributed, under the immortal Duke of Wellington, to give forty years of peace to the world. He is now engaged in the noble task of rolling back the tide of barbarism in conjunction with the French and Sardinians, and the best results may be anticipated from his gallantry and resolution.

(J. B—E. and J. H. S.)

ARNALDO, called from his birth-place DE BRESCIA, flourished in the first half of the twelfth century. After studying in France under Abélard, he returned to Italy and entered the church, the degeneracy and corruption of which at that time were a scandal to all true believers. Arnaldo set himself to denounce the profligacy and immorality of the great dignitaries of the church; and Brescia rose in rebellion against its bishop. The example was followed by other towns, and the contagion was only stopped by the banishment of Arnaldo. Retiring into France, the simple-minded monk was met and confronted by St Bernard, the famous abbot of Clairvaux, by whose means he was driven out of France. Returning to Rome, he found the people in rebellion against the Pope, put himself at their head, and for ten years kept the city in a state of chronic discontent with its spiritual head. This state of things lasted till Adrian IV. ascended the Papal throne. He excommunicated his own capital; and the Romans, utterly terrified, banished Arnaldo, who fled for safety into Campania. Peace, however, was not restored till his person was delivered up to the prefect of the city, who put him to death, burnt his bones, and threw the ashes into the Tiber in 1155.

ARNAUD DE MEYRVEILH, or MEREUIL, a poet of Provence, who wrote a book entitled *Las Recastenas de sa Contesse*, and a collection of poems and sonnets. Petrarch mentions him in his *Triumph of Love*. He is supposed to have died about the end of the twelfth century.

ARNAUD, *Daniel*, a still more celebrated troubadour than the preceding, flourished about the same period. He was born of a noble but poor family of Ribeirac in Perigord. When at the court of Richard I., an English jongleur challenged him to a trial of skill, and ten days were allotted for preparation. Arnaud, who was disinclined for the task, contrived, by listening at the door of his rival, to commit to memory the whole of the poem which the other had prepared and was learning to recite. When the day of trial was arrived, Arnaud requested permission to take the precedence, and gave forth the poem he had so cunningly appropriated. The jongleur was stupified with amazement, but Arnaud confessed the trick, the wager was withdrawn, and the king made rich presents to them both. Arnaud is extolled by Dante, Varchi, and Petrarch. Many of his amatory poems have been preserved, and some of them published by Raynouard. This name was likewise borne by several other troubadours.

ARNAUD DE RONSIL, *George*, son of an eminent surgeon at Paris, and some time professor of surgery in the College of St Côsme. On account of an accident that occurred while he was practising midwifery, he removed from Paris to London, where he acquired great repute by his operations, and his writings on surgical subjects. Before his time the treatment of *hernia* had been but imperfectly understood; and the surgeons of this country are indebted to the observations of Arnaud for many of those improvements which have since rendered their practice so successful in this branch of the art. He died in 1774.

ARNAUD, *Henri*, the celebrated pastor, leader, and historian of the Vaudois, was born in 1641 at La Torre in Piedmont, in which village also he was educated. How he spent the first years of his manhood is not known. It is said that he took service under William of Orange, afterwards William III. of England; but this, though likely, is not known for certain. He did not rise into notice till the time of the famous expedition of the Vaudois, who had been driven from their native valleys by the arbitrary cruelties of Victor Amadeus of Savoy. Driven into distant and widely-separated lands, the exiled Vaudois had been held together by the bonds of a common faith and a common patriotism, and had patiently and hopefully awaited their restoration. Twice they made the attempt, and twice they failed; and Arnaud, who seems to have had some hand in the second attempt, after leading off his followers, set out

[1] Jomini, *Guerres de la Révolution*, tom. ii., p. 252.

Arnaud.

for Holland, where he received advice and encouragement from the stadtholder, along with means for ensuring success to his next effort. When the English revolution of 1688 had been accomplished, Arnaud decided that the time for that next effort was at hand. Concentrating his followers in the great forest of the Pays de Vaud, he kept them for some time in concealment there. In September 1689 the Vaudois set foot in the valley of San Martino, which they reached after some bloody fighting with the French and Savoyard troops that opposed them. Their first care was to secure a strong position, which they luckily found, and fortified so well as to withstand the fiercest attacks of the French, repeatedly renewed during the course of the winter. The Vaudois boast, that during these engagements, while the foe was decimated, they lost not a single man. On the approach of summer Arnaud withdrew his troops from their stronghold, and led them to Angrona, where, just as they were on the point of abandoning themselves to despair, they learned that hostilities had broken out between France and Piedmont, and that their king, who had persecuted and expelled them, was now ready to receive them with open arms. Thus ended the "glorieuse rentrée des Vaudois dans leurs vallées"—effected, according to their own account, with a loss of only 30 men, while they make out that the joint losses of the French and Savoyards fell little short of 10,000 men. For a while the Vaudois were allowed to remain in peaceful possession of their ancient homes; but when the war of the Spanish Succession broke out, Arnaud and his followers took part in the combination against France, and rendered the allies much effectual service. But when that war came to a close, the ungrateful King of Piedmont once more joined the French monarch against his own subjects, and complied with the demands of that prince, that the Vaudois should be expelled from some of their valleys. The exiles, amounting in all to about 3000, found an asylum in Würtemberg. Their leader, who might have spent the remainder of his days in honour and comfort in England, choose rather to die, as he had lived, in the midst of his own people. He died at Schönberg in 1721, and every memorial that he left behind him was long cherished by his followers and their posterity.

Arnaud, *Marshal Le Roy de St*, was born in 1798. He was the son of an advocate who played an undistinguished part in the French Revolution, and who died when his son was only five years of age. After the usual training in the military schools, the young Le Roy entered the army, and volunteered in the cause of Greek independence. After some service in the East, he left the Greeks to their fate, and wandered, unattached, through Italy, Belgium, and England. At length an opening offered for his return home, when the old Bourbons were once more driven forth in 1830 to seek a foreign home. He obtained a commission, and in due time was sent to serve his country in Africa. His military character had there, for the first time, room to develop itself. His letters written at this time show him to have been a true soldier; faithful in the discharge; dashing forward, like his favourite Zouaves, at any obstacle that came in the way; daunted by no danger; and as reckless of his own life as of the lives of his men. When Louis Napoleon became President of the French Republic, St Arnaud began to pay court to him, and the President was far from unwilling to attach to his person a man like the African soldier, on whose loyalty he could rely. This confidence proved to be well founded when the great scheme of a restoration of the Empire rose to the mind of him who is now Napoleon III. The idea was no doubt due to the emperor himself; but the hand that gave it practical effect was St Arnaud's. The honours and rewards that were heaped upon him on the restoration of order, after the *coup d'état*, attest the value which his imperial master attached to his services. When the Russian war broke out St Arnaud was immediately fixed upon as the man of those then in France most competent to take the supreme command of the French army. Though his health was bad, and his constitution utterly broken up, he did not hesitate for a moment; but from the time when he assumed the chief power he executed with amazing energy and industry the numerous and responsible duties which it entailed upon him. His letters written at this date show that he regarded himself as the master and genius of the war; and there is no doubt that his death, which happened September 29, 1854, a few days after the victory of the Alma, was felt as a very serious blow both by France and England.

Arnaud

Arnauld.

St Arnaud really was what he was always proud of being thought—a Zouave. To gain a point there was no sacrifice too great for him to make. Restless, eager, thirsting for blood and battle-fields, he dashed at his point like a tiger on its prey. He was not capable of planning a great campaign; but, in the present dearth of military genius, he takes his place in the foremost rank of all the soldiers who have shared in the Russian war. Along with some of the best qualities of the soldier, St Arnaud possessed also some of the worst. He was, if not positively cruel, at least reckless of human life and suffering. His passions were strong, and, as they were perfectly uncontrolled, they often hurried him away into crimes and excesses, which in a less brave, less loyal, or less devoted man, might fail to obtain that pardon which his latterly heroic career and noble end ensure for St Arnaud. His letters, in 2 vols., Paris, 1855, are among the most interesting specimens of epistolary literature that have appeared in our age.

Arnaud, or Arnoldus, de Villa Nova, a famous physician and alchemist, who lived about the end of the thirteenth and beginning of the fourteenth century. He studied at Paris and Montpelier, and improved himself by visiting the schools of Italy and Spain. He was well acquainted with languages, particularly with the Greek, Hebrew, and Arabic. His desire after the acquisition of knowledge was ardent, but it carried him too far in his researches. He put unlimited faith in astrology, and published a prediction that the consummation of the world would take place in the year 1335. He practised physic at Paris for some time; but having advanced some new doctrines, he drew upon himself the resentment of the university; and his friends, fearing he might be arrested, persuaded him to retire from that city. He went to Sicily, where he was received by King Frederic of Aragon with the greatest marks of kindness and esteem. Some time afterwards this prince sent him to France to attend Pope Clement in an illness; and in this voyage he perished by shipwreck on the coast of Genoa about the year 1313.

Arnaud has been called the discoverer of the sulphuric, the muriatic, and the nitric acids, as well as of the essential oil of turpentine; and is said to have been the first to give regular scientific details of the process of distillation; but Dr Hoefer (*Histoire de la Chimie*, tom. i., p. 385) has shown that all these discoveries were made long before the time of Arnaud. His works, with a life prefixed, were first printed at Lyons in 1504, in one volume folio, and again in 1520 with the notes of Nicholas Tolerus; and at Basil in 1515 and 1585.

ARNAULD, Antoine, one of the greatest of French theologians and philosophers, was the twentieth child of Antoine Arnauld, the most famous advocate of his time, who in 1594 distinguished himself in the Parliament of Paris by pleading the cause of the university against the Jesuits. In the son that formidable society found during his active and polemical life a still more powerful and unwearied adversary. The whole family of the Arnaulds was devoted to the cause of Jansenism, and its female members, especially the celebrated "mère Angélique" are so identified with the history of the

abbey of Port Royal, that some notice of them will necessarily fall under the account of that remarkable institution. The elder Arnauld was himself a liberal supporter of Port Royal, and his wife, his six daughters, and five of his granddaughters, became nuns there. Three out of four sons who survived him became distinguished men.

Of these the youngest, Antoine, justly called by the Port Royalists, *le Grand*, was born at Paris, Feb. 6. 1612. After studying at the colleges of Calvi and Lisieux, he turned his attention to the study of law; but the influence of the Abbé St Cyran, director of Port Royal, and the advice of his mother, led him to choose the ecclesiastical profession. The same influence directed him to study the works of St Augustine, and he soon gave evidence of having entered into the spirit of that Father's theology. In 1641 he took his degree as Doctor of the Sorbonne, and after being twice rejected on formal grounds, he was in 1643 admitted a member of the *Society of the Sorbonne.*

Before this time his mind had undergone a deep change. The instructions of St Cyran, and the dying words of his mother, had impressed him with religious convictions of a more penetrative and influential kind than he had experienced hitherto, and from this time he devoted himself with all the ardour of his soul to the defence and propagation of what he believed to be the truth. In August 1643 he published his famous treatise *de la Frequente Communion*, expressly directed against the loose and scandalous doctrines of the Jesuits, who held on this subject that the beneficial reception of the sacraments required no preparation, and that open sin in the communicant is no bar to the benefits of the Eucharist. The severer doctrine of Arnauld soon drew down upon him the vengeance of the Jesuits; and the support of the parliament, and the approbation of a large body of prelates and doctors of the Sorbonne, were not sufficient to save him from their implacable hostility. He was obliged to seek safety in flight, and though his subsequent life had intervals of comparative security and repose, it may be said that from this time till his death he lived a harassed and persecuted fugitive.

His work on Frequent Communion is remarkable not merely on account of its important consequences to the author, but as the first theological work in France written in a pure and grammatical style, and entirely free from the barbarous subtleties of the preceding centuries.

In the year 1656 the college of the Sorbonne showed its complete subjection to the influence of the Jesuits, by effacing the name of Arnauld from the list of its doctors, and passing an act that no one should in future be admitted to the degree who did not sign the censure passed upon his heresies. The accusation against him was founded on two propositions in his *Letter on Absolution*—1*st*, that the five heretical propositions attributed to Jansenius were not contained in the *Augustinus*, and 2*d*, that the Fathers of the Church exhibit to us in the person of St Peter a saint who was deficient in saving grace.

From this time till 1668 Arnauld lived in concealment, incessantly occupied in writing against the Jesuits, and animating by his counsel and example the oppressed but powerful party who recognized in him their head and oracle. About the end of this period he composed the most enduringly valuable of his numerous works, the *Port Royal Grammar; New Elements of Geometry;* and the *Port Royal Logic, or Art of Thinking;* of all which it is sufficient to say that their value as important contributions to their several departments of science has not yet been superseded by the labours of subsequent writers.

In 1668 the so-called *Peace of the Church*, by Clement IX., recalled Arnauld from his exile; and on this occasion he was presented to the king and the papal nuncio, who received him with the outward forms of flattering distinction.

To convince the world of the falsehood of the Jesuitical accusation that the Jansenists were the abettors of Calvinism, Arnauld now devoted his controversial powers to the defence of the Roman Catholic faith against the Protestants. The great work composed chiefly by Nicole, but published under the name of Arnauld, *Perpétuité de la Foi de l'Eglise sur l'Eucharistie*, a voluminous and elaborate defence of transubstantiation, is the most important of these proofs of Jansenist orthodoxy.

His inextinguishable controversial ardour, and the persevering hostility of his enemies, once more drove Arnauld into exile. In 1679 he received a formal order from Louis XIV. to provide for his safety, and in the course of a few days he was again an exile in the Flemish city of Mons. From this time onward he had little rest till his death. Wandering from one city to another he kept up unweariedly the warfare in which he found his congenial element. Of the unquenchable activity of his spirit, a characteristic illustration is his well-known reply to Nicole, who urged him at one time to think now of desisting from his harassing labours and indulging in some repose. "Rest!" said the untired warrior; "shall we not rest in Eternity!" At Brussels in 1694 his manifold labours came to an end, in the 82d year of his age. His body was buried where he died; his heart, at his own request, was carried to Port Royal, of which he had been in life the most redoubtable defender.

The life-long warfare of Arnauld was not confined alone to the defence of Jansenism. His love of truth and of discussion found subjects for his polemical activity in the works of his most valued and intimate friends. Descartes and Malebranche, Pascal and Domat, Nicole and Gilbert of Choiseul, and his protector Pope Innocent XI., all in various ways gave scope to his unconquerable controversial zeal.

"In Arnauld," says Mr Baynes, the able translator of the Port Royal Logic, "are found singularly united many of the best virtues of his time. Love of truth and freedom, fearless intrepidity, stainless honour, and inflexible justice, are ever found in his writings. Bowing to the authority of the church, yet confronting the thunders of the Vatican—rejecting the old philosophy, yet reproducing the truth which it contained—accepting the new, yet fearlessly discussing its dogmas with Descartes—he vindicated incessantly the claims of reason and faith, with an earnestness and impartiality which the love of truth alone could inspire. There is, indeed, scarcely any sight, even in that age of great men and great controversies, more inspiring than that of Arnauld doing battle, single-handed, with all that was mightiest, both in church and state—replying to every attack with an energy which was never wearied, a fertility of resource which was never exhausted, and a freshness of thought and power of argument rarely equalled, and perhaps never excelled."—*Introduction to Port Royal Logic.* (Edin. 1850.)

The works of Arnauld compose, in the edition of 1783, 48 vols. in 4to. This immense collection comprehends treatises on theology, philosophy, literature, science, and politics, all giving proof of that wonderful power which, in the midst of labours so constant and multifarious, never showed any symptom of decline. Arnauld also had a considerable share in the famous translation of the Bible by his nephew De Saci.

ARNAY-LE-DUC, a town of France, in the department of Cote d'Or, which carries on a pretty good trade. It is seated on the Auxois, in a valley near the river Aroux. Pop. in 1846, 2331. Long. 4. 26. E. Lat. 47. 7. N.

ARNDT, John, a famous Protestant divine of Germany, born at Ballenstadt, in the duchy of Anhalt, in the year 1555. He died in 1621. His *Treatise on True Christianity* has been translated into several languages.

ARNE, Thomas Augustine, doctor of music, was born

in 1710, in King Street, Covent Garden, where his father was an upholsterer. He served three years with an attorney; but his strong propensity for music prevailed over the law, and he finally devoted himself to that science, in which he soon became so eminent as to receive the degree of doctor from the University of Oxford in 1759. He was an extensive composer, and adapted upwards of thirty musical pieces for the stage. They are characterized by a natural ease and elegance, a flow of melody, and a fulness and variety without affected or extraneous modulation. His most celebrated works are *Artaxerxes*, paraphrased from Metastasio; the *Masque of Comus;* the *Opera of Operas*, a burletta; the *Guardian Outwitted;* and the *Rose;* some of which have taken a permanent hold of the stage. Dr Arne died March 5. 1778.

ARNHEIM, a fortified town of Holland, capital of the province of Guelderland, 50 miles south-east of Amsterdam, and 35 miles E.S.E. of Utrecht, with both of which it is connected by the Dutch-Rhenish Railway. This has been selected as the point of communication between the various railways of Germany and Holland. It stands on the right bank of the Rhine, about three miles below the point where the Yssel branches off from it, and which is here crossed by a bridge of boats. It is well built, and its neighbourhood abounds with beautiful villas, parks, and gardens. It has a grammar school and several learned societies, courts of assize and commerce, a governor's palace, and extensive new barracks. The church of St Eusebius, in which the old dukes and counts of Guelderland lie buried, contains many sepulchral monuments of interest. It has a good port on the river, an active general trade, and manufactures of woollen, cotton, paper, tobacco, &c. Pop. in 1850, 18,671. Lat. 51. 58. 46. N. Long. 5. 54. 43. E.

ARNICA, a botanical genus of the natural order of Compositæ. The English name of *A. montana* is Leopard's bane. It is a powerful narcotico-acrid, and has been used in medicine, especially in chronic rheumatism, and as a diuretic in atonic dropsy.

ARNISÆUS, Henningus, a philosopher and physician of great reputation about the beginning of the seventeenth century. He was born at Halberstadt in Germany, and was professor of physic in the university of Helmstadt. His political works are much esteemed. The most remarkable of them is his book *De Autoritate Principum in Populum semper Inviolabili*, printed at Frankfort in 1612. He wrote also upon the same doctrine his three books, *De Jure Majestatis*, printed at the same place in 1610; and his *Reflectiones Politicæ*, printed at Frankfort in 1615. He went to Denmark by invitation, and was made counsellor and physician to the king. He travelled into France and England, and died at Fredricksborg in 1636. Besides the pieces already mentioned, he wrote several philosophical, medicinal, and poetical treatises.

ARNO (ancient Arnus), the celebrated river of Florence, which rises in Monte Falterona, in the Apennines, and descends into the valley of Casentino, in Upper Tuscany. It passes the town of Bibbiena into the plain of Arezzo, where it receives the Chiana as a tributary, and enters the narrow valley of Laterina. Thence it issues through the rocky defile Dell' Inferno, pours into the lovely Val D'Arno, sweeps beneath the woods of Vallombrosa, and after receiving the Sieve, enters the plain of Florence, and proudly flows through the celebrated capital of Tuscany. Ten miles below Florence, it is confined in an artificial channel, formed by the ancient Etruscans, for the purpose of draining the plain. It receives several tributaries, and enters the plain of Pisa, which it traverses; and after a further course of eight miles, falls into the Tuscan sea. Its whole winding course is about 140 miles. At Florence it is 400 feet wide, but is fordable in summer. It is liable to sudden floods, and then is impetuous, carrying down with it immense quantities of earth and stones, by which its bed is elevated; in many places requiring frequent embankment. On the banks of the upper Arno, are vast accumulations of fossil bones of the elephant, rhinoceros, hippopotamus, and bear, especially between Arezzo and Florence.

ARNOBIUS, one of the earliest apologists of Christianity in the west, was a teacher of rhetoric at Sicca (now Keff), in Numidia, towards the end of the third century. Becoming dissatisfied with his ancestral faith, and harassed with doubts, which pursued him even in his dreams, he became desirous of embracing Christianity, and for this purpose applied to the bishops for admission into the church; but his former violent hostility to the faith led them to distrust him, and, before they would consent, they insisted on some proofs of his sincerity. In compliance with this demand, he wrote against the Gentiles, refuting the absurdities of their religion, and ridiculing their false gods. In this treatise he has employed all the flowers of rhetoric, and displayed great learning; but it is defective in arrangement, and manifests but an imperfect knowledge of the Christian faith. His work bears the title *Adversus Gentes*, and there are several editions of it. The best is that of *Orelli*, Lips. 1816. 2 vols. 8vo. He wrote also a piece entitled *De Rhetoricæ Institutione*, which is not extant.

ARNOLD of Brescia (*Arnaldus*, or *Arnulphus Brixiensis*), distinguished himself in the twelfth century, as the founder of a sect which opposed the wealth and corruption of the Roman clergy. He went into France, where he studied under the celebrated Abelard. Upon his return to Italy he put on the habit of a monk, and opened his invectives in the streets of Brescia. He pointed his declamation against the bishops, the clergy, the monks, and finally against the Roman pontiff himself; to the laity only was he indulgent. In 1139 he was cited to appear before a grand council at Rome. His accusers were the bishop of Brescia, and many others whom he had ridiculed and insulted. Nor from his judges could he look for much indulgence. He was found guilty, and sentenced to perpetual silence. Upon this he left Italy, crossed the Alps, and found a refuge in Zurich. After the death of Pope Innocent II. he returned to Italy, headed an unsuccessful revolt in Rome, and was ultimately condemned to death and crucified in 1155. His name is deserving of being remembered for the boldness of his attempt to lower the power of the pope and his clergy, in an age when the papacy existed in all the plenitude of its influence. His followers were known as *Arnoldists*.

Arnold, *Benedict*, a noted officer in the war of American Independence. He was born in Connecticut in 1740; engaged with zeal in the cause of his countrymen, and rose to be a general of brigade. He was appointed, after a wound in the leg, to the command of Philadelphia, where he committed such acts of rapacity, that he was tried by a court-martial in 1779, and reprimanded. On this he resigned his commission; and appears from that time to have entered on the dishonourable scheme, for which now he is chiefly remembered, that of betraying his country to the British. These negotiations led to the death of the gallant and unfortunate Major André, while the guilty Arnold escaped to the British headquarters. He retained in the British the rank he had held in the American army, and was employed in Virginia and Connecticut; in both of which he committed great devastation, especially in his native province, where he butchered the garrison of Fort Turnbull, and burnt New London. He was taken by the French while in our service in the West Indies, but made his escape. On the peace, he retired to Britain, where he died in 1801. His duel with Lord Lauderdale, in 1792, on account of some vituperative expressions used by his Lordship at a public meeting, is well know

Arnold.

Arnold Strutthan von Winckelried, one of the heroes of Swiss independence. When Leopold Duke of Austria, in conjunction with the nobles of Switzerland, attempted in 1386 to destroy the liberty of the people, the whole force which the Swiss had to oppose a regular army of 4000 soldiers amounted but to 1400 men, undisciplined and badly armed. They met under the walls of Sempach in Lucerne, and the Swiss were about to retreat, when the fate of the day was decided by Arnold, who rushed forward, and seizing in his arms the spears pointed against his friends, received them in his bosom. The enemy was routed; Leopold and most of his noble followers being slain; and the independence of Switzerland was secured. See Switzerland.

Arnold, *Samuel*, doctor of music, was born in 1740, and was received into the royal chapel at an early age, where he was successively the pupil of Mr B. Gates and Dr Nares. In 1764, he became the composer for the orchestra of Covent Garden Theatre; and two years afterwards also had the same office at the Haymarket. He is the author of 40 musical dramas, among which are *The Maid of the Mill*, *Inkle and Yarico*, *The Son-in-law*, *The Battle of Hexham*, *The Surrender of Calais*, *The Babes in the Wood*, *The Mountaineers*, with the oratorios of *Saul*, *Abimelech*, *The Prodigal Son*, and *The Resurrection*. In 1783, he was appointed organist and composer to the king; and in 1789, conductor of the Academy of Ancient Music. We owe to him the publication of the works of Handel and Boyce. He died in 1802, and was interred in Westminster Abbey.

Arnold, *Thomas*, a clergyman of the Church of England, was born at West Cowes, in the Isle of Wight, on the 13th of June 1795. He was the son of William and Martha Arnold, the former of whom occupied the situation of collector of customs at Cowes. Deprived at an early age of his father, who died suddenly of spasm in the heart in 1801, his initiatory education was confided by his mother to her sister, Miss Delafield, who with affectionate fidelity discharged to him the office with which she had been intrusted. From her tuition he passed to that of Dr Griffiths, at Warminster, in Wiltshire, in 1803; and in 1807 he was removed to Winchester, where he remained until 1811, having entered as a commoner, and afterwards become a scholar of the college. In after life he retained a lively feeling of interest in Winchester School, and remembered with admiration and profit the regulative tact of Dr Goddard, and the preceptorial ability of Dr Gabell, who were successively head-masters during his stay there.

As a schoolboy he was not particularly distinguished by any of those attainments which usually determine the honours of the class. Beyond a very retentive memory, a love for solitary reading, and a certain precocity in the writing of English verse, he afforded but few indications of any superior power of intellect or any decided impulse towards literary pursuits. He was shy and somewhat stiff in his manners, inclined to prefer the society of persons more advanced in life to that of his schoolmates, and somewhat inordinately resolute in holding by any opinion he had formed or any purpose he had adopted. At the same time it is easy to trace in the favourite pursuits of his boyhood, and in the development of his youthful character, many of the most characteristic features of the future man. He was strong and fast in the friendships he formed amongst his fellows. He was already a careful and curious observer of character, and instinctively cleaved to the noble and the gentle, the vigorous and the pure, in whomsoever found. He was almost from infancy devotedly attached to the study of history and geography, as well as to ballad poetry. Already, however, he had begun to allot separate places in his mind to the romantic and to the real in narration; and whilst he relished both, he steadily refused to accept the one for the other. No boy had a heartier enjoyment of the myth or the ballad; but even as a boy he had begun to look with distrust upon much of the ancient history as, "if not totally false, at least scandalously exaggerated." In the stillness of these studies, and in the stream of schoolboy society, there can be little doubt that (according to "a true saying" of the great German poet) the talents and the character of the future historian of Rome and head master of Rugby, began to receive their peculiar mould.[1]

From Winchester he removed to Oxford in 1811, where he became a scholar at Corpus Christi College; in 1815 he was elected Fellow of Oriel College; and there he continued to reside till 1819. This interval was diligently devoted to the pursuit of classical and historical studies, to preparing himself for ordination, and to searching investigations, under the stimulus of continual discussion with a band of talented and congenial associates, of some of the profoundest questions in theology, ecclesiastical polity, and social philosophy. The authors he most carefully studied at this period were Thucydides and Aristotle, and for their writings he formed an attachment which remained to the close of his life, and exerted a powerful influence upon his mode of thought and opinions, as well as upon his literary occupations in subsequent years. Herodotus also came in for a considerable share of his regard, but more, apparently, as a book of recreation than one for work. In prosecuting his historical studies he adopted the plan which he afterwards recommended to his students in his lectures at Oxford, that of selecting some one period of which he made himself thoroughly master, and with reference to which he surveyed the events and persons that came under his notice either in the course of his more general reading, or as an observer of what was going on around him. In theology, his mind, accustomed freely and fearlessly to investigate whatever came before it, and swayed by an almost scrupulous dread of aught that might appear to savour of insincerity, was doomed to long and anxious hesitation upon several points of fundamental importance before arriving at a serene and settled acceptance of the great verities of Christianity. Once satisfied, however, of these, his faith remained clear and firm; and having received his religion, not by tradition from men, but as the result of an earnest, penetrating, and honest examination of the evidence on which it rests, he not only held it with a steadfast grasp, but realized it and felt it as a living and guiding power. From this time forward his life became supremely that of a *religious* man. He had not only embraced orthodox sentiments, and seen his way to an honest conformity with the ecclesiastical arrangements and worship of the church to which he belonged, but he had experienced within his own soul the renovating and transforming energy of divine truth. Christianity was no longer a something which he had taken upon him; it was a life, a nature within him. Long exercised with doubts and difficulties as to the person and claims of Jesus Christ, he had at length reached to such an intense and all-subduing conviction on these points that a continual consciousness of love and adoration, of joy and confidence towards the Redeemer, seems to have occupied his bosom. To the name of Christ he was prepared to "surrender his whole soul," and to render before it "obedience, reverence without measure, intense humility, most unreserved adoration."[2] It was his joy and consolation when lost amid the mysteries which sur-

[1] "Es bildet ein Talent sich in der stille;
Sich ein charakter in dem strom der Welt."—*Goethe.*

[2] Sermons, vol. iv. p. 210.

round the being and government of the Infinite, to remember that, "in that unknown world in which our thoughts become instantly lost, still there is one object on which our thoughts and imaginations may fasten, no less than our affections; that, amidst the light, dark from excess of brilliance, which surrounds the throne of God, we may discern the gracious form of the Son of Man."[1] This vivid realization of Christ as the centre and source of his religion, communicated peculiar animation as well as a single-hearted simplicity to his piety. To be like Christ—to please Christ—to have communion with Christ—to enjoy blessing from Christ:—these became the leading ideas and the ever-present impulses of his religion. Hence not only had all religious doubt and perplexity disappeared, but a new impulse was communicated to his whole spiritual life; his battle with evil in all its forms became more intense; his activity became more subject to a high sense of duty and an earnest desire to acquit himself well as a good soldier of Jesus Christ; and amidst the throng and bustle of this world he ever maintained a conscious sense of the spiritual state which had been revealed to him, and to which he felt himself continually drawn by his love to his Redeemer. He did not often talk about religion; he had no inclination to gossip about his experience, or dwell upon the frames and feelings through which he passed; he had not much of the accredited phraseology of piety even when he discoursed on spiritual topics. But no man could observe him for any length of time without feeling persuaded that more than most men he was directed by religious principle and feeling in all his conduct. The fountain of his piety was in his heart's core; and its streams mingled easily with all the issues of his life. As his biographer has beautifully remarked, "his natural faculties were not unclothed but clothed upon; they were at once coloured by, and gave a colour to, the belief which they received."[2]

He left Oxford in 1819 and settled at Laleham near Staines, where he was occupied chiefly in superintending the studies of seven or eight young men who were preparing for the university. His spare time was devoted to the prosecution of studies in philology and history, more particularly to the study of Thucydides, and of the new light which had been cast upon Roman history and upon historical method in general by the researches of Niebuhr. He was also occasionally engaged in preaching, and it was whilst here that he published the first volume of his sermons. Shortly after he settled at Laleham he entered into the marriage relation with Mary youngest daughter of the Rev. John Penrose, rector of Fledborough, Nottinghamshire.

Under the plastic influences of domestic life, and amid the congenial occupations which divided his time at Laleham, his character was gradually maturing, his intellectual powers were becoming more fully developed, his opinions on social and ecclesiastical questions were acquiring consolidation and precision, and he was laying up a stock of experience and forming plans which demanded a much wider sphere for their operation than such a post as that which he now occupied could present. It was not long before such a sphere opened before him. After nine years spent at Laleham, he was induced to offer himself as a candidate for the head-mastership of Rugby, which had become vacant; and though he entered somewhat late upon the contest, and though none of the electors were personally known to him, he was nevertheless successful. He was elected in December 1827; in June 1828 he received priest's orders; in April and November of the same year he took his degree of B.D. and D.D.; and in August entered on his new office.

In one of the testimonials which accompanied his application to the trustees of Rugby, the writer stated it as his conviction, that "if Mr Arnold were elected, he would change the face of education all through the public schools of England." Nobly was this somewhat hazardous pledge redeemed by him in whose name it had been given. Arnold's head-mastership at Rugby constituted a new era in the history of public education in England. By his skill, devotedness, and high moral earnestness, even more than by his scholarship or his direct tutorial influence, he completely "changed the face of education" at that great institution, and set an example which has acted upon all the educational institutions of the empire. Under his superintendence the school became not merely a place where a certain amount of classical or general learning was to be obtained, but a sphere of intellectual, moral, and religious discipline, where healthy characters were formed, and men were trained for the duties, and struggles, and responsibilities of life.

Rugby was privileged to enjoy his superintendence for nearly fourteen years. During this period his energies were chiefly devoted to the business of the school; but he found time also for much literary work, as well as for an extensive correspondence. Five volumes of sermons, an edition of Thucydides, with English notes and dissertations, a History of Rome in three vols. 8vo, besides numerous articles in reviews, journals, newspapers, and encyclopædias, are extant to attest the untiring activity of his mind, and his patient diligence during this period. His interest also in public matters was incessant, especially in such as bore upon the social welfare and moral improvement of the masses. Ecclesiastical questions occupied at all times a large share of his regards; he was earnest for church reform, and continually disposed to take a despairing view of the prospects of the hierarchy. From the outset he had watched with intense interest the progress of those opinions and tendencies at Oxford which have of late years excited so much public attention, and have issued in results which Arnold was among the first to predict.

In 1841 Dr Arnold received from Lord Melbourne, then prime minister, the offer of the chair of Modern History at Oxford, an offer which he accepted with peculiar satisfaction. The situation was one which connected him once more with the university where his own earlier studies had been conducted, and for which he ever retained the liveliest affection; its duties were not onerous, and they fell in with the course of his favourite pursuits; and it afforded him a provision against the time when he should be compelled to retire from the responsibilities of such an institution as Rugby, and seek that lettered ease to which, amidst all the distractions of his active life, he was continually looking forward as the ultimatum of his earthly ambition. On the duties of this new office he entered on 2d December 1841, by delivering his inaugural lecture, amidst circumstances which he felt to be peculiarly gratifying and flattering. Seven other lectures were delivered during the first three weeks of the Lent term of 1842; the whole have been published since his death.

A few months after the delivery of his lectures, Arnold was suddenly removed from his earthly duties and anticipated enjoyments by an attack of angina pectoris. The Midsummer vacation had arrived, and he was preparing to set out with his family to Fox How, a favourite retreat, where he had purchased some property and built a house, in Westmoreland. After a busy day spent in various duties, he retired to rest apparently in perfect health. Between five and six next morning he awoke in severe pain. All attempts to arrest the fatal malady proved fruitless. He bore with heroic fortitude and Christian resignation his sufferings,

[1] Sermons, vol. iii. p. 90.

[2] Life by Stanley, vol. i. p. 31.

until eight o'clock, when he expired. The day on which he died was Sunday, the 12th of June 1842. "What that Sunday was in Rugby," says his biographer, "it is hard fully to represent: the incredulity—the bewilderment—the agitating inquiries for every detail—the blank, more awful than sorrow, that prevailed through the vacant services of that long and dreary day—the feeling as if the very place had passed away with him who had so emphatically been in every sense its head—the sympathy which hardly dared to contemplate, and which yet could not but fix the thoughts and looks of all on the desolate house where the fatherless family were gathered round the chamber of death." His remains were interred on the following Friday in the chancel of Rugby chapel, immediately under the communion-table.

We have no space left to attempt a delineation of the separate features of Arnold's character. We can only remark in general, that the great peculiarity and charm of his nature seemed to lie in the regal supremacy of the moral and the spiritual element over his whole being and powers. His intellectual faculties were not such as to surpass those of many who were his contemporaries; in scholarship he occupied a subordinate place to several who filled situations like his; and he had not much of what is usually called tact in his dealings either with the juvenile or the adult mind. What gave him his power, and secured for him so deeply the respect and veneration of his pupils and acquaintances, was the intensely religious character of his whole life. He seemed ever to act from a severe and lofty estimate of duty. To be just, honest, and truthful, he ever held to be the first aim of his being. Amid the trials and the duties of life alike, he "endured, as seeing Him who is invisible." Like Milton, who had also been a schoolmaster, his principle seems to have been—"Were it the meanest under-service, if God, by his secretary Conscience, enjoin it, it were sad for me if I should draw back." With all this, there was intense sympathy with his fellows, the tenderest domestic affections, the most generous friendship, the most expansive benevolence. But to understand aright his claims upon our respect and homage, the history of his life must be read at large. As has been truly observed by one who seems to have known him well—"His Thucydides, his history, his sermons, his miscellaneous writings, are all proofs of his ability and goodness. Yet the story of his life is worth them all."—*Edin. Rev.*, vol. lxxxi., p. 234. His life has been most ably written by the Rev. A. P. Stanley, M.A., in two volumes, 8vo. Lond. 1845. (W. L. A.)

ARNOLDUS, Gothofredus, pastor and inspector of the churches of Perleberg, and historiographer to the king of Prussia, was born at Annaburg, in the mountains of Misnia, in 1666. He was a zealous defender of the Pietist sect, and composed a great number of religious works, particularly an *Ecclesiastical History*, which exposed him to the resentment of the divines, and another giving an account of the doctrines and manners from the first ages, in which he frequently animadverts upon Cave's *Primitive Christianity.* He died in 1714.

ARNSTADT, a town in the principality of Swartzburg, Sonderhausen, on the river Gera, 14 miles south-east of Gotha. It has a castle, four churches, a workhouse, an orphan asylum, and two hospitals; with an active corn and timber trade; and manufactures of woollen, linen, cotton, paper, leather, &c. Pop. 6000.

ARNULPH, or Ernulph, bishop of Rochester in the reign of Henry I. He was born in France, where he lived some time a monk in the monastery of St Lucien de Beauvais. The irregular lives of the monks determined him to quit their society, and on the invitation of his former prior Lanfranc, archbishop of Canterbury, he removed to England, and took up his abode in the monastery of Canterbury. After the death of Lanfranc, Arnulph was made prior of the monastery of Canterbury, and afterwards abbot of Peterborough. In 1115 he was consecrated bishop of Rochester, which see he held nine years, and died in March 1124, aged 84. Arnulph wrote in Latin an account of the foundation, endowment, charters, laws, &c., of the church of Rochester: it is known by the title of *Textus Roffensis,* and is preserved in the archives of the cathedral of Rochester. It has been printed in Thorpe's *Registrum Roffense.*

ARNWAY, John, D.D., a clergyman distinguished for his piety and exemplary charity, was descended of a good family in Shropshire, and inherited a considerable estate. He zealously espoused the cause of King Charles I.; and after suffering imprisonment and the sequestration of his estate during the civil wars, he retired, on the ruin of Charles's cause, to the Hague. There he published, in 1650, a tract entitled *Tablet, or Moderation of Charles I., Martyr, with an Alarum to the Subjects of England.* From the Hague he went to Virginia, where he died in 1653.

AROER, the name of four towns mentioned in Scripture. (1.) A town on the north side of the river Arnon, the ruins of which were found by Burckhardt, under the name of Araayr. (2.) One of the towns built, or probably rebuilt, by the tribe of Gad. Its ruins are supposed to be those of Ayra, noticed by Burckhardt. This Ayra, about seven miles south-west from Szalt, is probably the same with the *Array*-el-Emir, visited by Legh, on his way from Heshbon to Szalt, and which in Berghaus's celebrated map of Palestine is placed nine English miles W.N.W. of Rabbah. (3.) A city in the tribe of Judah. (4.) A city in the south of Judah, to which David sent presents after recovering the spoil of Ziklag. Dr Robinson supposes that he found traces of this town in the valley of Ararah, about 20 geographical miles south by west from Hebron.

AROIDEÆ, a natural order of plants, the species of which are acrid, and many of them very poisonous, as the genus *Arum;* but the poisonous principle is dissipated by heat. Some of the order give out much heat when flowering, and some at that time have an offensive smell.

ARONA, a town of the Sardinian States, province of Novara, near the southern extremity of Lake Maggiore. Lat. 45. 45. 57. N. Long. 8. 33. 6. E. It is well built; and has a strong castle, a gymnasium, several churches, a hospital, a port and dockyard on the lake, and a considerable trade. Pop. 4000. In 1697 the people of Milan erected, on an eminence in this vicinity, a colossal statue in honour of San Carlo Borromeo, a man distinguished for his piety and benevolence, who was born here in 1538, and afterwards became cardinal and archbishop of Milan, where he died in 1584. The statue stands on a granite pedestal 46 feet high, and is itself 66 feet in height. In the interior of the statue are stairs leading up to its head, which is so large that four persons can sit in it at a table.

AROO, or Arru, a group of islands in the Eastern Archipelago, lying about 80 miles south-west of Papua, between Lat. 5. 20. and 6. 55. S.; and Long 134. 10. and 134. 45. E. These islands produce pearl, mother-of-pearl, tortoiseshell, birds of paradise, edible birds'-nests, trepang, &c. The inhabitants are a mixture of the Malay and Australasian negro races. The largest of these islands is 70 miles long and 20 broad.

AROPH, a contraction of *aroma philosophorum,* a name given to saffron.

Aroph Paracelsi, a name given to a kind of chemical flowers, probably of the same nature with the Ens Veneris, elegantly prepared by sublimation from equal quantities of lapis hæmatites and sal ammoniac.

ARPINAS, or Arpino, Giuseppe Cesare, a famous painter, born in the year 1560, at the castle of Arpinas, in the kingdom of Naples. He lived in great intimacy with Pope Clement VIII. who conferred upon him the honour

of knighthood, and many other marks of friendship. His paintings of Roman history are the most esteemed of all his works. He died at Rome in 1640.

ARPINO (the ancient *Arpinum*), a town of Naples, in the province of Terra di Lavoro, pleasantly situated on an eminence 6 miles south of Sora. It has a considerable trade, and manufactures woollen cloth, leather, parchment, and paper. In the vicinity is an extensive paper mill which gives employment to 200 persons. Pop. 11,000. This was a very celebrated city of the Volsci, and afterwards came into the possession of the Samnites, from whom it was taken by the Romans in B.C. 305. During the latter period of the Roman Republic it was a flourishing municipal town; but it is chiefly distinguished as the birthplace of two of the most illustrious men in Roman history, Caius Marius, and Marcus Tullius Cicero. The latter frequently alludes to Arpinum in his letters, and describes the inhabitants as rustic and simple in their manners, but possessing many virtues. His favourite villa was situated in a plain beneath the town, on the banks of the little river Fibrenus. Remains of the walls and of the ancient city are still to be seen.

ARQUA, a market-town of Austrian Italy, among the Euganean hills, in the delegation of, and 12 miles south-west from, Padua. Pop. 1000. Here Petrarch resided during the latter years of his life, and here he died on the 19th July, 1374. "His ashes are preserved in the churchyard of the town, in a sarcophagus of red marble, raised on four pilasters on an elevated base, and preserved from an association with meaner tombs."—

"They keep his dust in Arqua where he died;
The mountain village where his latter days
Went down the vale of years; and 'tis their pride—
An honest pride—and let it be their praise,
To offer to the passing stranger's gaze
His mansion and his sepulchre; both plain
And venerably simple, such as raise
A feeling more accordant with his strain
Than if a pyramid formed his monumental fane."

"The house in which Petrarch resided is on the edge of a little knoll overlooking two descents, and commanding a view, not only of the glowing gardens in the dales immediately beneath, but of the wide plains, above whose low woods of mulberry and willow, thickened into a dark mass by festoons of vines, tall single cypresses and the spires of towers are seen in the distance which stretches to the mouth of the Po and the shores of the Adriatic. The chair in which the poet breathed his last is still shown among the precious relics of Arquà."—*Childe Harold*, canto iv. st. 31, and note 9.

ARQUES, a small decayed town of France, department of Seine Inferieure, on a navigable river of the same name, 3 miles south-east of Dieppe. It was once a very considerable place, and its castle, now in ruins, was an important stronghold in the middle ages. In the vicinity of this town Henri IV., with about 6000 or 7000 men, gained a victory over the army of the league, consisting of 30,000, commanded by the Duke of Mayenne, on the 21st Sept. 1589. The victory was severely contested, and Henri had encountered many personal dangers, when the arrival of the Count of Châtillon at the head of 500 arquebusiers decided the fate of the day.

ARRACAN, a maritime province of Eastern India. It was formerly an independent kingdom, but fell by conquest to the Burmese in 1783, and was by them ceded to the British in 1826. It is distributed into the districts of Akyab, Ramree, and Sandoway; and is bounded by the Chittagong district on the north, from which it is separated by the small river Naaf; by the Yoomadoung range of mountains on the east, dividing it from Ava and the British district of Pegu; and on the south and west by the Bay of Bengal. It lies between Lat. 16. 2. and 21. 33.; and Long. 92. 10. and 94. 50. Its length from its northern extremity to Cape Negrais is about 400 miles; its greatest breadth is in the northern part, where it falls little short of 90 miles, but it gradually diminishes towards the south, until at the extreme point it tapers to a narrow strip not more than 15 miles across. The coast is studded with several islands, the most important and fertile of which are Cheduba, Ramree, and Shapoora. The Yoomadoung Mountains, forming part of the great chain stretching southward from Assam, attain a considerable elevation, averaging in this part from 3000 to 4000 feet, while one portion of the range called the Blue Mountain, situate about Lat. 22. 37. Long. 93. 11., rises 8000 feet above the level of the sea. Over these mountains there are several passes; that called the Aeng route, which leads from the village of that name to the Burmese capital, being superior to any of the others. On the summit of the ridge by this route, and immediately on the frontier line between the British and Ava territories, the Burmese had constructed the stockade of Nariengain. The fortification was originally of little consequence, deriving its importance solely from its position, which commanded the ascent as well from the side of Ava as from that of Arracan; but during the war of 1852 the Burmese had so added to the strength of the works that the place was deemed unassailable, except by mortars and rockets. A small force, however, under the command of Captain Nuthall, accompanied by Captain Sutherland, succeeded, on the night of the 6th January 1853, in arriving unobserved within a short distance of the spot. After a brief pause the men moved silently towards the stockade, and it being ascertained that the garrison were asleep, orders were given to charge the gate in force, and the fort regarded as impregnable was thus captured by surprise.

The principal rivers of the province are the Myoo, Kuladyne or Arracan River, Leyryo, Talak, and Ayeng. A range of hills of no great height skirts the sea-shore; and the adjacent valleys are covered with thick jungle, and filled with wild animals, among which are the elephant, tiger, leopard, bison, and wild hog; but the natural history of Arracan has not received much attention, and the cursory notices of travellers afford the only existing information. Owing to the moist temperature (the periodical rains continuing from May till October, and occasionally to December) this tract of country is frequently flooded; and being much intersected by rivers and inlets of the sea, communication between the villages is generally maintained by means of boats. The soil is fertile, but the frequent rains and exhalations under the burning sun of the tropics are adverse to the European constitution. The staple produce is rice, of which the crops are represented as being the richest in India, and affording, in addition to the demand for home consumption, a large surplus for exportation. The other chief productions are sugar, cotton, tobacco, hemp, and indigo. The fruits, which are abundant and of superior quality, comprise pine-apples, plantains, mangoes, jacks, sweet limes, cocoa-nuts, and others requiring a tropical climate. The forests produce an abundance of excellent timber, the principal trees being oak and teak; but owing to the difficulty of conveyance from the hills, timber is usually imported from the district of Bassein. Salt is produced in great plenty by solar evaporation, and forms a principal article of exportation. Limestone is procured from the adjacent islands.

The aboriginal inhabitants of Arracan are termed Mughs, who with Burmans, Mussulmans, sundry hill-tribes, and immigrants from various places, constitute the population. If, as is generally believed, the increasing numbers of a people indicate a wise and benevolent government, Arracan bears testimony to the character of that under which it has been placed. At the period of its occupation by the British the population did not exceed 100,000. In 1831 it had increased

to 173,000, and in 1839 to 248,000. It is now upwards of 321,000. The Mughs follow in their religion the Bhuddist doctrines which are universally maintained throughout Burmah. The priests are selected from all classes of men, and one of their chief employments is the education of children. Instruction is consequently widely diffused, and few persons, it is said, are found in the province who are unable to read. The qualifications for entering into the priestly order are good conduct and a fair measure of learning; such conduct at least as is good, according to Bhuddish tenets, and such learning as is esteemed among their votaries. Polygamy is in general practice.

The natives of Arracan trace their history as far back as A.D. 701, and give a lineal succession of 120 native princes down to modern times. According to them their empire had at one period far wider limits, and extended over Ava, part of China, and a portion of Bengal. This extension of their empire is not, however, corroborated by any known facts in history. At different times the Moguls and Peguers carried their arms into the heart of the country. The Portuguese, during the era of their greatness in Asia, gained a temporary establishment in Arracan. But in 1783 the province was finally conquered by the Burmese; from which period until its cession to the British in 1826 under the treaty of Yandaboo, its history forms part of that of Burmah.

The old city of Arracan, formerly the capital of the province, is situate on an inferior branch of the Kuladyne River. Its remoteness from the ports and harbours of the country, combined with the extreme unhealthiness of its locality, have led to its gradual decay subsequently to the formation of the comparatively recent settlement of Akyab, which place is now the chief town of the province. Arracan is distant north-east from Akyab fifty miles; Lat. 20. 42. Long. 93. 24. (E. T.)

ARRACK. In India every kind of spirituous liquor is known under the general appellation of arrack; and hence the various accounts given of the mode of making it, and the materials used. The manufacture of arrack was formerly carried on by the Portuguese at Goa, but has been transferred for the most part from that place to Batavia. At Goa there are different kinds; single, double, and treble distilled. The double distilled, which is that commonly sent abroad, is weak compared with Batavia arrack; yet, on account of its peculiar and agreeable flavour, is preferred to all the other arracks of India. This flavour is attributed to the earthen vessels used to draw the spirit; whereas at Batavia they use copper stills.

The Pariah arrack made at Madras, and the Columbo and Quilone arrack at other places, being fiery, hot spirits, are little valued by the Europeans, though highly prized among the natives.

The Goa arrack is obtained by a double process of distillation from a vegetable juice called toddy, which flows by incision from the cocoa-nut tree. The liquor thus obtained holds but a sixth, and sometimes an eighth part of alcohol, or pure spirit.

Batavia arrack is obtained by distillation from rice and sugar. A fiery spirit called samshew, which is mixed with arrack, is imported into Batavia from China, chiefly for the use of the Chinese settlers.

ARRAGON. See ARAGON.

ARRAIGNMENT, in *Law*, the arraigning or setting a thing in order, as a person is said to arraign a writ of novel disseisin, who prepares and fits it for trial; but this term more properly denotes the calling of a person to answer in form of law upon an indictment, &c.

ARRAN, an island on the west coast of Scotland, near the mouth of the river Clyde, which forms part of the county of Bute. It is about 20 miles in length, by from 8 to 11 in breadth, and contains a superficial area of 165 square miles, or 105,814 acres, of which about 14,431 are cultivated. This island is of an extremely rugged and mountainous surface, particularly in the northern part, in which the valleys are deep and romantic. The principal mountain is Goatfell, which rises, according to accurate measurement, 2945 feet above the level of the sea, and is clothed with lichens and mosses. A few others approach to the same elevation. There are five small lakes and several streamlets in the island.

The quadrupeds are not numerous. A few red deer, the remains, it is said, of a numerous breed, still find shelter among the mountains; and wild goats are still harboured in those parts. The cattle and sheep, which were formerly small, have been improved by the introduction of a larger breed. The birds are, eagles, hooded crows, plovers, curlews, black cock, and other species of grouse, which are exceedingly numerous in the mountains. Ptarmigans, which were formerly seen, have now disappeared. Limestone, marl, and slate, are found in different parts, and there are also indications of coal; while in the mountains are found marble, jasper, agates, cairngorms, and a fine species of rock-crystal called the Arran diamond. A considerable manufacture of sulphate of baryta as a pigment has been carried on in Glen Sannox for several years. The geology of the island is an epitome of that of Scotland. The mountains of the north, especially Goatfell, consist of granite, covered on the flanks by mica slate, a red sandstone conglomerate, especially on the eastern shores, and may be traced easily around the whole island. On the eastern side carboniferous lime is found at several points, chiefly at Corrie, where several strata divided by shale, resting on a white sandstone, are quarried. In the southern part of the island an extensive trap formation is the chief visible rock. Several beds of anthracite were formerly worked on the north-east coast. This coal formation rested on the red sandstone, and was covered by white sandstone. Numerous veins of most beautiful pitchstone and pitchstone porphyry traverse the red sandstone, especially at Drimodoon, and between Brodick and Lamlash. Shoals of herring frequent the shores, and the herring fishery is prosecuted to a great extent, no fewer than 200 fishing-vessels, well-manned and properly fitted out, and belonging to the island, being employed in it. Arran has two remarkably fine harbours, Lamlash on the east, and Loch Ranza on the north-west side. Flax is cultivated in small quantities, and linens and some woollens are manufactured. About two-thirds of the island belong to the Duke of Hamilton, who takes much interest in its improvement, and has expended a considerable sum in making roads, bridges, and small harbours.

Brodick Castle, beautifully situated on an eminence surrounded by waving plantations, remained in ruins until the year 1845, when its noble proprietor, the Duke of Hamilton, completed, with great good taste, its reconstruction on the model of the ancient fortress. At the time of the memorable interregnum when Edward I. was endeavouring to crush the spirited efforts of Wallace and Bruce for the independence of their country, it was taken and held by the English under Sir John Hastings. It did not, however, remain long in their possession; "for James, Lord Douglas, who accompanied Bruce to his retreat in Rachrin, seems in the spring of 1306 to have tired of his abode there, and set out accordingly, in the phrase of the times, to see what adventure God would send him. Sir Robert Boyd accompanied him; and his knowledge of the localities of Arran appears to have directed his course thither. They landed on the island privately, and appear to have laid an ambush for Sir John Hastings, the English Governor of Brodick, and surprised a considerable supply of arms and provisions, and nearly took the castle itself. When they were joined by Bruce, it seems probable that they had gained Brodick Castle. At least tradition says that from the battlements of the tower he saw the supposed signal fire on Turnberry nook." After the settlement of the Scottish crown by Bruce, the castle of Brodick, as well as the greater part of Arran, was the property of the High Steward of Scotland, who, by failure of male-heirs to Bruce, succeeded to the throne under the title of Robert II. In 1455, it was stormed and levelled to the ground by the Earl of Ross, who had espoused the cause of the Earl of Douglas against his sovereign. Its next possessor was Sir Thomas Boyd, a court favourite, who married King James I.'s eldest sister, and received from that monarch the earldom of Arran as her marriage dowry. On the disgrace of the Boyds, Sir Thomas was divorced from his royal spouse, and the princess's hand, with her earldom of Arran, bestowed upon Lord Hamilton, in whose family, with the exception of a few interruptions, it has remained until this day.

Brodick Bay is a beautifully curved plain, girt with a beach of sand, and ornamented with neat cottages and villas, flourishing plantations, and cultivated fields, which, as they retire inwards,

are met by the wildly-contrasting valleys of Glenrosa, Glensheraig, and Glencloy. In Glencloy are the remains of an ancient fort, which tradition points out as having afforded shelter to Bruce's partizans, who had arrived in Arran before himself, while Brodick Castle was in the possession of the English; and at the head of the glen there are also the supposed remains of a Druidical circle.

About five miles from Brodick, in the middle of a beautiful semicircular bay, lies the neat little village of Lamlash. Sheltered by the Holy Island—an irregular cone 900 feet high—this bay forms an excellent harbour for the accommodation of ships of all sizes, while its surrounding scenery cannot be beheld without delight by all lovers of the picturesque.

The Holy Isle was once the site of an ancient cathedral, said to have been founded by St Molios, a disciple of St Columba, who not considering the discipline of Iona sufficiently rigid, retired for greater seclusion to this lonely isle, whence he carried the light of Christianity among the pagan inhabitants of Arran.

Behind the village of Lamlash are Glens Alaster and Meneadmar, at the head of which may be seen the remains of an ancient sepulchral cairn, measuring 200 feet in circumference. It is believed to cover the ashes of those who fell in a battle fought upon the spot; as on removing some of the stones, several stone coffins were found buried underneath. At the southerly point of the bay, about three miles from Lamlash, is King's-cross Point, whence Robert Bruce is said to have embarked for the coast of Carrick.

Near the basaltic promontory of Drimodoon, there are a number of water-worn caves, one of which, called the King's Cave, is famed for having been the residence of the patriot Bruce on his first arrival in the island. It is 114 feet long, 44 broad, and 47½ high. Some of the other caves are equally large; one is called the King's Kitchen; another his cellar; and a third his stable. The hill above the caves is called the King's Hill, from its connexion with Bruce. At the northern side of this hill, on the farm of Tormore, are the remains of a very perfect and interesting Druidical circle, called Suidhe choirr' Fhionn, or Fingal's Cauldron-seat.

Loch Ranza is about a mile in length, and, during the fishing season, is a place of great resort, 300 boats sometimes lying at anchor in the bay at the same time. The ruins of Loch Ranza Castle stand upon a small peninsula near the entrance of the Loch. This castle is not heard of until the year 1380, when it is enumerated among the royal castles, as a hunting-seat of the Scottish sovereigns. The roof having fallen in, it is now fast falling into decay.

Off the south-east point of Arran lies the low rocky islet of Pladda, with a lighthouse having two fixed lights, 130 and 77 feet above high-water, and visible 16 and 13 miles respectively, in clear weather. Lat. 55. 25. N. Long. 5. 7. W. Pop. in 1851, 8203.

ARRAN ISLES, a group of small islands off the coast of Galway in Ireland, constituting the barony of Arran. They are sometimes called South Arran, to distinguish them from the island of Arranmore or North Arran, in the county of Donegal. The three principal islands of the group are Arranmore or Inishmore, Inishmain, and Inishere. On the first is a lighthouse exhibiting a bright revolving light, 498 feet above high-water mark. Lat. 53. 7. 38. N. Long. 9. 42. 22. W. The bay of Killany, to the N. of the village of that name, is the principal harbour in the group. The inhabitants of these islands, amounting in 1851 to 3333, are employed in fishing and agriculture, and are much behind in education and improvement. The area of the whole group is 11,287 acres.

The Arran islands abound in antiquities and religious remains, and are said to have contained at one time no less than 20 churches and monastic establishments. Most of these were in the island of Inishmore, called by the natives *the Island of the Saints*. The circular fort of Dun-Angus, built of uncemented stones on a cliff overhanging the sea, is the most striking of these ancient remains. The holy wells, altars, groves, &c., are still visited by numbers of enthusiastic devotees.

ARRAS (the *Nemetacum* of the Romans), a fortified city of France, chief town of the arrondissement of the same name, and also of the department of Pas de Calais, and formerly capital of the province of Artois. It is situated on both sides of the Scarpe, where that river receives the Crinchon, 32 miles north-east of Amiens, and 100 miles N.N.E. of Paris. The town is well built, and adorned with many handsome edifices, such as the town-house, cathedral, citadel, arsenal, barracks, theatre, &c. Its fine old Gothic cathedral was utterly destroyed during the revolutionary phrenzy. It is the seat of a bishop, and of a court of assize; and has a royal society, a college, a diocesan seminary, an institution for the deaf and dumb, and schools of design and belles lettres. It has also a public library of 36,000 volumes, a picture gallery, museum, and botanical garden. Its chief manufactures are lace, woollens, hosiery, beet-root sugar, salt, soap, and earthenware; with a considerable general trade in wine, oil, grain, sugar, &c. The river Scarpe is navigable up to the town. Arras is the birthplace of the assassin Damiens, the two brothers Robespierre, and Lebon. Pop. in 1846, 24,321. Lat. 50. 17. 31. N. Long. 2. 46. 49. E.

Arras is very ancient, and was the chief town of the *Atrebates* as early as the time of Cæsar. (See ATREBATII.) In 407 it was destroyed by the Vandals, and afterwards by the Normans in 880. It gives name to a treaty concluded here between France and Burgundy in 1435, and to another in 1482, between Maximilian of Austria and Louis XI. of France, by which Burgundy and Artois were given to the Dauphin as a marriage portion. In 1493 it came again into the possession of Maximilian. In 1640 the troops of Louis XIII. took Arras; and by the peace of the Pyrenees in 1659, France was confirmed in the possession of the town.

ARRASWISE, in *Heraldry*, is used for the placing of any object of a square form in such a position as to exhibit a perspective view of its top and two of its sides.

ARRAY, in *Law*, the ranking or setting forth of a jury, or inquest of men impannelled on a cause.

ARRAYERS, ARRAGERS, or ARRAITORES, is used in some ancient statutes for such officers as had charge of the soldiers' armour, and their proper accoutrement. In some reigns commissioners were appointed for this purpose.

ARRENTATION, in the forest laws, implies the licensing the owner of lands in a forest to inclose them with a low hedge and a small ditch, in consideration of a yearly rent.

ARREOYS. Among the more singular secret societies which mankind have formed, was one in Otaheite and the neighbouring islands for the destruction of their own species, called *Arreoy*, *Arehoe*, or *Earowie*.

Whether Mendana, Quiros, and the earlier navigators of the South Pacific Ocean, discovered this society, does not appear: it was, at any rate, reserved for those of later date to unfold its principles and peculiarities, though its constitution is still enveloped in mystery, the members having been bound to the strictest secrecy.

The society of Arreoys consisted of hundreds or perhaps thousands of both sexes, who engaged to destroy their own offspring at the moment of birth. It was chiefly composed of persons distinguished by valour and merit, and hence one or more individuals of each family of the chiefs were of the number. All the men professed themselves warriors, and were in general stout and well made; the greatest trust and confidence were reposed in them; and it rather appears that the women consisted of the higher ranks only. There were different gradations in this community, which were recognized by the mode of tattooing: the more profusely the men were tattooed, the higher was their rank in society; the first were called *Ava bly areema tutowe*; 2. *Areema bly*; 3. *Ahowhoa*; 4. *Harrotea*; 5. *Eote ole*; 6, 7. *Po*; and youths training up were designed *Mo*; but the meaning of these names is not explained. By the fundamental laws of the society, the offspring must be destroyed, yet it is not known with certainty by whom or in what particular manner; the murder was always perpetrated in secret, probably by strangulation; all the attendants were excluded; for it is said, were they to witness it they would be adjudged guilty of participation, and put to death. Sometimes the mother, animated by natural affection, tried to preserve her infant, and resisted the persuasions of her husband and his brother Arreoys, who wished to consign it to destruction. But in general the enormity of the crime did not appal the females, though they are ascribed as affectionate and tender. We find a dancing girl pregnant by an Arreoy expressing herself thus to the English navigators: "Perhaps the

Arrest.

Etooa or deity of England might be offended with the practices of the Arreoys, but her own was not displeased with them. However, she promised if we would come from England for her child, she might perhaps keep it alive, provided we gave her a hatchet, a shirt, and some red feathers." That the rules of the community were very strict, may be inferred from an instance given by Captain Bligh. A chief, a member of the society, married a sister of the king of Otaheite, by whom he had eight children, and the whole were destroyed at their birth! Nor did this enormity seem to originate from any other source, as the parents afterwards adopted a nephew as their heir.

Probably the murderous practices of the Arreoys in the South Sea Islands originated in some religious principle; but it is the mission and the glory of Christianity to abolish the enormities of heathenism. Through the patient labours of Christian missionaries in Otaheite and other islands of the Pacific, many of the natives have been converted to Christianity; and such has been the influence on society at large, that the revolting practices of the Arreoys, with the monstrous and cruel rites of idolatry, have been banished from the islands which have been visited with the purifying light of the gospel.—See Ellis's *Polynesian Researches*, vol. i.

ARREST (from the French *arrester*, *arrêter*, to stop or stay), is the restraint of a man's person, for the purpose of compelling him to be obedient to the law, and is defined to be the execution of the command of some court of record or officer of justice.

Arrests are either in civil or in criminal cases.

I. *As to an arrest in civil cases.* The arrest must be by virtue of a precept or order out of some court, and must be effected by corporal seizing or touching the defendant's body, or as directed by the writ, *capias et attachias*, take and catch hold of. And if the defendant make his escape, it is a *rescous* or rescue, and attachment may be had against him, and the bailiff may then justify the breaking open of the house in which he is, to carry him away.

Arrests on mesne process, before judgment obtained, are, since the 1st and 2d Vict., c. 110, no longer allowable, except under special circumstances and under the authority of a judge's order. Such order may be obtained on an affidavit to the satisfaction of the judge that the defendant is about to leave the country.

A judgment creditor may arrest his debtor under a writ of *capias ad satisfaciendum*, but since the 7th and 8th Vict., c. 96, the debt must exceed L.20, exclusive of costs; and if the debtor does not make satisfaction he must remain in custody, until discharged under the acts for the relief of insolvent debtors.

The following persons are *privileged* from arrest: 1*st*, Peers of the realm; members of parliament, not only when the house is sitting, but for such a period before the first meeting and after the dissolution of a parliament as may enable them conveniently to come from and return to any part of the kingdom, and also for 40 days after every prorogation, and 40 days before the next appointed meeting. 2*d*, Peeresses by birth; peers of Scotland; peeresses by marriage; Irish peers; members of convocation actually attending thereon (8th Henry VI., c. 1). 3*d*, Bishops; ambassadors, or the domestic servant of an ambassador, really and *bona fide* acting in that capacity (7th Anne, c. 12); the Queen's servants, marshal, &c. 4*th*, Attorneys, witnesses subpœnaed, suitors, and all other persons, while necessarily attending the courts of justice, or going to or from the same (*eundo, morando, et redeundo*). 5*th*, Clergymen, performing divine service, and not merely staying in the church with a fraudulent design (50th Edward III., c. 5, and 1st Richard II., c. 16, as amended by 9th Geo. IV., c. 31).

The arrest of any privileged person is irregular *ab initio*, and the party may be discharged on motion. The only exception is as to indictable crimes, such as "treason, felony, and breach or surety of the peace."

There are now no longer any places where persons are privileged from arrest, such as the Mint, Savoy, Whitefriars, &c., on the ground of their being ancient palaces. See statutes 8th and 9th Will. III., c. 27, § 15; 9th Geo. I., c. 28, § 1; 11th Geo. I., c. 22; as amended by 1st Geo. IV., c. 116.

Except in cases of treason, felony, or breach of the peace, an arrest cannot be made on a Sunday, and if made it is void (29th Car. II., c. 7); but it may be made in the night as well as in the day.

II. *As to an arrest in criminal cases.* All persons whatsoever are, without distinction, equally liable to this arrest, and any man may arrest without warrant or precept, and outer doors may be broken open for that purpose.

The arrest may be made, 1*st*, by warrant; 2*d*, by an officer without warrant; 3*d*, by a private person without warrant; or, 4*th*, by a hue and cry.

1. Warrants are ordinarily granted by justices of the peace on information or complaint in writing and upon oath, and they must be indorsed when it is intended they should be executed in another county (see 11th and 12th Vict., c. 42). They are also granted in cases of treason or other offence affecting the government by the privy council, or one of the secretaries of state, and also by the chief or other justice of the court of Queen's bench in cases of felony, misdemeanour, or indictment found, or criminal information granted in that court.

2. The officers who may arrest without warrant are,—justices of the peace, for felony or breach of the peace committed in their presence; the sheriff and the coroner in their county for felony; constables for treason, felony, or breach of the peace committed in their view,—and within the metropolitan police district they have even larger powers; and watchmen from sunset to sunrise.

3. A private person is bound to arrest for a felony committed in his presence, under penalty of fine and imprisonment.

4. The arrest by hue and cry is where officers and private persons are concerned in *pursuing* felons, and such as have dangerously wounded another.

The remedy for a wrongful arrest is by an action for false imprisonment. (R. M—M.)

In Scotland the law of arrest in criminal procedure has a general constitutional analogy with that of England, though the practice differs with the varying character of the judicatories. Colloquially the word arrest is used in compulsory procedure for the recovery of debt; but the technical term applicable in that department is Caption, and the law on the subject is generically different from that of England. There never was a practice in Scottish law corresponding with the English arrest in mesne process; but by old custom a warrant for caption could be obtained where a creditor made oath that he had reason to believe his debtor meditated flight from the country, and the writ so issued is called a warrant against a person *in meditatione fugæ*. Imprisonment of old followed on ecclesiastical cursing, and by fiction of law in later times it was not the creditor's remedy, but the punishment of a refractory person denounced rebel for disobedience to the injunctions of the law requiring fulfilment of his obligation. The system was reformed and stripped of its cumbrous fictions by an act of the year 1837. Althougth the proceedings against the person could only follow on completed process, yet, by a peculiarity of the Scottish law, documents executed with certain formalities, and by special statute bills and promissory-notes, can be registered in the records of a court for execution against the person as if they were judgments of the court. In 1835 imprisonment for debts not exceeding a hundred pounds Scots or L.8, 6s. 8d. was abolished. (J. H. B.)

Arrest of Judgment.

Arrest *of Judgment* is the assigning just reason why judgment should not pass, notwithstanding verdict given, either in civil or in criminal cases, and from intrinsic causes arising on the face of the record.

Under the New Common Law Procedure Act, 15th and

16th Vict., c. 76, § 143, the omitted facts, however, may, by leave of the court, be suggested. Although these motions are not abolished altogether, they will therefore not be fatal as heretofore, but the truth of the suggested facts omitted will be tried and judgment be given thereon; and this judgment will have the same effect, under section 144, as if the suggested facts were in the original pleadings. (R. M—M.)

ARRESTMENT, in *Scottish Law*, denotes that process by which a creditor detains the goods or effects of his debtor in the hands of third parties till the debt due to him shall be paid. It is divided into two kinds,—1*st*, Arrestment in security, used when proceedings are commencing, or in other circumstances where a claim may become, but is not yet enforceable; and 2*d*, Arrestment in execution, following on the decree of a court, or on a registered document under a clause or statutory power of registration, according to the custom of Scotland. By the process of arrestment, the property covered by it is merely retained in its place—to realize it for the satisfaction of the creditor's claim a farther proceeding called Forthcoming is necessary. By old practice, alimentary funds, or those necessary for subsistence, were not liable to arrestment. By a statute of 1837, the wages of labourers and manufacturers, so far as necessary to their subsistence, are declared not to be arrestable. The question of necessity for subsistence is decided according to the discretion of the judge resorted to. This restriction was enacted on account of serious doubts whether this remedy, unknown in other parts of the empire, did not tend to foster a system of credit among the working classes, which put them at the mercy of petty dealers, and disturbed the business of their employers, in whose hands their wages were arrested. It is still a question much debated, whether the remedy—limited though it be by the act of 1837, and by an act of 1845, abolishing arrestments of wages in *dependence* in small-debt actions—is not liable to abuse. (J. H. B.)

ARRHÆ, money given by the purchaser in evidence of the completion of a bargain. Hence the Scottish term *Arles*, which, however, is not recognized in law.

ARRIA, the heroic wife of Cæcina Pætus, who, when her husband was ordered by the Emperor Claudius to destroy himself and hesitated to do so, stabbed herself, and presented the dagger to him with these words—"*Pæte, non dolet*"—(Pætus, it does not pain me).—Plin. *Ep.* iii. Dion Cass. lx.

ARRIAN (Ἀῤῥιανός), a distinguished Greek historian and philosopher, who lived in the time of the Emperors Hadrian, Antoninus Pius, and Marcus Aurelius. He was a native of Nicomedia, born about the end of the first century of our era, and was one of the most distinguished disciples of the famous Epictetus. In A.D. 124, he lived at Athens, where he made the acquaintance of the Emperor Hadrian, who was so much struck with his practical wisdom as to raise him to several high offices; and under Antoninus he obtained even the consulship. The only other event of his life of which we know anything is, that he was appointed governor of Cappadocia. Arrian himself proudly disdains giving us any information of himself; and his life, written by Dion Cassius, is lost.

History and philosophy are greatly indebted to Arrian; for, being a disciple of Epictetus, who himself did not write any work, Arrian determined to be to him what Xenophon had been to Socrates, and published his philosophical lectures in eight books, of which only the first half is extant; but the portion which has come down to us gives us a most exalted view of the ethical philosophy of Epictetus and the Stoics generally. The work bears the title Διατριβαὶ Ἐπικτήτου, and is contained in Schweighaüser's *Philosophiæ Epicteteæ Monumenta*, vol. iii. A second work, by which Arrian testified his attachment to his great master, bears the title Ἐγχειρίδιον Ἐπικτήτου, a short manual of moral philosophy, compiled from the lectures of Epictetus, which for many centuries was regarded both by Pagans and Christians as the best book on the subject. It has been published in a great many editions: the best is in the collection of Schweighaüser, mentioned above.

Among Arrian's own original works, the first and foremost is his account of the expedition of Alexander the Great in seven books. It contains the best and most authentic account of that conqueror's career, being based upon the lost works of Aristobulus and Ptolemy, the son of Lagus, both of whom accompanied the king during the expedition. Editions: J. Gronovius, Lugd. Bat. 1704, fol.; Schmieder, Lipsiæ, 1798, 8vo; Ellendt, *Regim. Pruss.* 1832, 2 vols. 8vo; Krüger, Berlin, 1835 and 1848, 2 vols. 8vo; 1851, 1 vol. 8vo; and Sinteius, Lips. 1849. Connected with this is a treatise on India, in the Ionic dialect, which he wrote separately, in order not to be obliged to interrupt the history of Alexander. Besides these, he wrote a work on the chase, a periplus of the Black Sea, and a manual of tactics; but many other works which are ascribed to him by the ancients have not come down to us. Certain descriptions of the coasts of the Sea of Azov and the Red Sea, which are ascribed to him, are probably the productions of a later period.

Arrian's style is simple, lucid, and manly; and his imitation of Xenophon is visible, not only in his style and diction, but even in the subjects on which he wrote. His language, though pure Attic, presents some peculiarities which are not found in the works of his great model. (L. S.)

ARRIAZA, JUAN BAUTISTA, a modern Spanish poet of considerable reputation, was born in 1770, at Madrid. He published his *Primicias*, an anonymous volume, in 1797. He was secretary to the Spanish embassy at London, where he wrote his *Emilia*. He then went at Paris; returned home in 1807; and became a violent partizan of the service party, attacking the Cortes and the patriots in prose and verse in his *Discursos Politicos*, and *Poesias Patrioticas*. His style is better than his subject, and his verses display harmony and expression. He died in 1837 at Madrid.

ARRIEGE. See ARIEGE.

ARRIS. See ARCHITECTURE.

ARRIS-FILLET, or *Tilting-fillet*, a triangular piece of wood used to raise the slates or lead of a roof against the shaft of a chimney or a wall, in order to throw off the rain more readily. The term arris is also applied to a wooden gutter in the form of a V.

ARROE, a small fruitful island in the Baltic, 10 miles south of Fuhnen. It is 14 miles long, averaging 5 in breadth, and has a population of 10,000. It belongs to Denmark. Lat. 54. 54. N. Long. 10. 20. E.

ARROW, a missile weapon of offence, slender pointed and sometimes barbed, to be cast or shot with a bow. See ARCHERY.

ARROW-Makers were formerly called *fletchers*, and, as well as bowyers, were persons of great consequence in the commonwealth.

ARROW, more properly ARREE, ROOT, is the name given to the farina obtained from two species of Scytaminean plants, *Maranta arundinacea*, and *M. indica*; the former coming to us from the warmer regions of the New World, the other from the East Indies. It is largely used as a food for infants, and for persons with delicate stomachs, or subject to diarrhœa. It is a pure starch, soluble in cold water, and forms a viscid, clear solution with warm water. With milk it forms an excellent pudding.

The quantity of arrowroot imported to Britain in 1852, from British possessions, was 364 cwt. 3 qr. 18 lb.; from foreign countries, 736 cwt. 3 qr. 4 lb. Till 1853 there was a duty of 6d. per cwt. on the former, and 2s. 6d. on the latter, now reduced to the uniform rate of 4½d.

ARROWSMITH, Aaron, an eminent geographer and hydrographer, born at London in 1750. He published, in 1817, a new General Atlas, 4to, and produced a great number of maps and charts. His map of the world on Mercator's projection is much esteemed. He died in 1823.

ARSACES VI., otherwise Mithridates, a king of the Parthians, spoken of in the First Book of Maccabees. He considerably enlarged the kingdom of Parthia by his good conduct and valour. There were thirty-one kings of the dynasty of the Arsacidæ. See Vaillant, *Arsacidarum imperium, sive regum Parthorum historia ad fidem numismatum accommodata.* Paris, 1725.

ARSENAL (from the Romaunt *arthenal*, a citadel), originally denoted exclusively a magazine of naval stores and warlike apparatus, giving probability to the etymology which derives the word from the Latin *arx navalis*, a naval citadel. Now, however, the term is applied to a repository of warlike stores, whether for land or sea service. The naval arsenals are, however, still the more numerous, and will be found described at length under the article Dockyards.

The great arsenal of Britain (if we except the Tower) is that of Woolwich, where all warlike stores and apparatus are not only preserved, but manufactured in the immense buildings devoted to the purpose. (See Woolwich.) Deptford, Chatham, Sheerness, Portsmouth, and Plymouth, are the great naval arsenals. In France, there are military arsenals at Paris, Strasburg, Metz, Lille, &c., and five great maritime arsenals, the chief of which are those of Brest, Toulon, and Rochefort; next to them L'Orient and Cherbourg. There are also inferior arsenals at Dunkirk, Havre, Saint Servan, Nantes, Bordeaux, and Bayonne. The other principal naval arsenals in Europe are those of Russia, at St Petersburg, Cronstadt, and Sebastopol; of Holland, at Anvers, Flushing, Helvoetsluys, and the Texel; of Prussia, at Danzig; of Hamburg; of Denmark, at Copenhagen; of Turkey, at Constantinople; of Italy, at Genoa, Villa-franca, Livorno, Spezzia, Civita Vecchia, Naples, Ancona, Venice, and Trieste; of Spain, at Cadiz, Carthagena, and Barcelona, and the British one at Gibraltar; of Portugal, at Lisbon; of Britain, at Malta and Corfu, &c. The principal naval arsenals of the United States are at New York, Boston, and Baltimore; of Brazil, at Rio Janeiro and Bahia; of La Plata, at Buenos Ayres and Monte Video; of Chili, at Valparaiso; and of Mexico, at Vera Cruz.

ARSENIC, a metal, the salts of which are deadly poisons. See Mineralogy, Medical Jurisprudence, and *Index*.

ARSENIUS, a deacon of the Roman Church, of great learning and piety. He was appointed by the pope to go to the Emperor Theodosius, as tutor to his son Arcadius. Arsenius arrived at Constantinople in the year 383. The emperor happening one day to go into the room where he was instructing Arcadius, his son was seated and the preceptor standing. At this he was exceedingly displeased, took from his son the imperial ornaments, made Arsenius sit in his place, and ordered Arcadius for the future to receive his lessons standing uncovered. Arcadius, however, profited little by his tutor's instructions, for some time after he formed a design of despatching him. The officer to whom Arcadius had applied for this purpose divulged the affair to Arsenius, who retired to the deserts of Scete, where he passed many years in exercises of devotion. He died at Troë, aged 95.

ARSINOE, mother of Ptolemy I., was a concubine of Philip of Macedon, who gave her in marriage, while pregnant, to Lagus. The name was afterwards borne by several of her descendants, and was also given to various cities. See Egypt.

ARSON is the malicious and wilful burning of the house or outhouse of another man, or wilfully setting fire to one's own house, if a neighbour's house be also burnt.

To constitute the offence, there must be an intent to injure or defraud some other person; and, therefore, if a house is fired by negligence or mischance, it does not amount to arson, but is only a trespass.

The crime of arson attaches in the following instances:—1*st*, Unlawfully and maliciously setting fire to any dwelling-house, any person being therein. For this crime the offender is liable to the punishment of death. 2*d*, Unlawfully and maliciously setting fire to any church or chapel, or to any chapel for the religious worship of persons dissenting from the united church of England and Ireland, or to any house, stable, coachhouse, outhouse, warehouse, office, shop, mill, malthouse, hopsast, barn, or granary, or to any erection used in carrying on any trade or manufacture, or any branch thereof, whether in the possession of the offender or any other person, with intent to injure or defraud any person. The punishment for this offence is transportation for life, or for not less than fifteen years, or of imprisonment not exceeding three years (7th Will. IV., and 1st Vict., c. 89, § 2). 3*d*, Unlawfully and maliciously setting fire to any hovel, shed, or fold, not attached to any house, or to any farm-building, or any building or erection used in farming land, or to any hay, straw, wood, or other vegetable produce, or to any implements of husbandry, being in any farm-house or farm-building, with intent to set fire to such farm-house or farm-building, subject to the like punishment (7th and 8th Vict., cap. 62). 4*th*, Unlawfully and maliciously setting fire to any station, or other building belonging to any railway, dock, canal, &c. For this the punishment is transportation for life, or for not less than seven years, or imprisonment, with or without hard labour, for not less than three years (14th and 15th Vict., cap. 19, § 8). 5*th*, And by the 9th and 10th Vict., cap. 25, § 7, any overt act to *attempt* to set fire, with such intent that, if the offence were complete, the offender would be guilty of felony and liable to transportation for life, shall be deemed felony, with a punishment of transportation for fifteen years, or of imprisonment for two years, although the same be not actually set on fire. And every male offender, under the statutes 7th and 8th Vict., cap. 62, and 9th and 10th Vict., cap. 25, if under the age of eighteen years, is also liable, at the discretion of the court, in addition to any other sentence, to be either publicly or privately whipped; 6*th*, Servants negligently or carelessly setting fire to houses or buildings, are, under the 14th Geo. III., cap. 78, § 84, liable to forfeit L.100, or in default, to be imprisoned for eighteen months with hard labour.

In Scotland, the offence equivalent to arson in England is known by the more expressive name of wilful fire-raising. The later statutes cited above do not apply to Scotland where the crime is punishable capitally by old consuetudinary law. The public prosecutor has the privilege, as in other such cases, of declining to demand capital punishment, and it is usual so to act when the burning has not taken place under conditions likely to endanger life. (R. M—M.)

ARSURA, a term used in ancient times for the melting of gold or silver, either to refine them or to examine their value. The method of doing this is explained in the Black Book of the Exchequer, ascribed to Gervaise, in the chapter *De Officio Militis Argentarii*, being in those days of great use, on account of the various places and different manners in which the king's money was paid.

Arsura is also used for the loss or diminution of the metal in the trial. In this sense a pound was said *tot ardere denarios*, to lose so many pennyweights.

Arsura is likewise used for the dust and sweepings of silversmiths, and others who work in silver melted down.

ART and PART, in *Scottish Law*, the aiding or abetting in the perpetration of a crime.

ARTA, a town of Albania in European Turkey, sandjak of Janina, situated on a river of the same name, and about seven miles from the Gulf of Arta. It has several mosques,

a number of Greek churches, a large cathedral, a ruined convent of the ninth century, now a caravansera; a citadel, some good houses and shops; and a fine old bridge over the river, consisting of an arch eighty feet high, and several smaller ones. It has about 8000 inhabitants, with manufactures of coarse cottons and woollens, leather, capotes, and embroidery; and the general trade is considerable. It is surrounded with gardens, orange-groves, and vineyards, and there is much wood in its vicinity. Arta occupies the site of the ancient Ambracia, and traces of its old walls are still to be seen. See AMBRACIA.

ARTA, GULF OF (the *Ambracius Sinus* of the ancients), a gulf of the Ionian Sea, in Lat. 39. N. Long. 21. E., having on the north Albania, and on the south and east Acarnania. Its length is 25, and its greatest breadth 10 miles, with a depth varying from 13 or 14 to 36 fathoms. Its entrance is only 700 yards across, outside of which is a bar composed of gravel, coarse sand, and sea-weed, with fifteen feet of water when shallowest. The north shore is for the most part low and swampy, and has encroached considerably on the water: the southern shore consists of high land with bold promontories, clothed with rich and extensive forests. It has been long celebrated for its excellent fish, of which the red and gray mullet are the most plentiful; and soles and eels also abound. The famous battle of Actium, which decided the fate of Augustus and Mark Antony, was fought near the entrance of this gulf in B.C. 31.

ARTABA, an ancient measure of capacity used by the Persians, Medes, and Egyptians. The Persian artaba is represented by Herodotus as equal to one Attic medimnus and three chœnices, or 102 Roman sextarii = about $12\frac{1}{4}$ gallons; but, according to Suidas, Hesychius, Polyænus (*Strat.* iv. 3, 32), and Epiphanius (*Pond.* 24), it only contained 1 Attic medimnus = 96 sextarii, or about $11\frac{1}{2}$ English gallons. The Egyptians used two measures of this name; the old artaba, containing $4\frac{1}{2}$ Roman modii = 72 sextarii = about $8\frac{3}{4}$ gallons, though Galen makes it exactly 5 modii; and the new artaba which contained $3\frac{1}{3}$ modii = $53\frac{1}{3}$ sextarii = about $6\frac{1}{2}$ gallons.

ARTABAZUS, the son of Pharnaces, commander of the Parthians and Chorasmians in the famous expedition of Xerxes. After the battle of Salamis he escorted his sovereign to the Hellespont with 60,000 chosen men; and after the battle of Platæa, in which Mardonius engaged in opposition to his wishes and advice, he made a noble retreat into Asia with 40,000 men under his command.

ARTAXERXES, the name of several kings of Persia. See PERSIA, and ESTHER.

ARTEDI, PETER, an eminent naturalist, was born in Sweden in the year 1705, in the province of Angermania. His parents were poor, but found means to give him a liberal education, and with this view sent him to the college of Hurnesand. Intending to embrace the ecclesiastical profession, he went in 1724 to Upsal; but he turned his attention to medicine from the strong bent of his mind for the study of natural history, in which science he made rapid progress, and soon rose to considerable eminence, particularly in the department of ichthyology, the classification of which he remodelled upon philosophical principles. This arrangement afterwards became popular over Europe. In 1728 his celebrated countryman Linnæus arrived in Upsal, and a lasting friendship was formed between these two great men. In 1732 both left Upsal; Artedi for England, and Linnæus for Lapland; but before parting, they reciprocally bequeathed to each other their manuscripts and books in the event of death. In 1735, however, they met again at Leyden, where Artedi was introduced to Seba, and employed in preparing for the press the third volume of that eminent naturalist's *Thesaurus*, which chiefly related to fishes. He intended, as soon as that work was finished, to return to his native country, and publish the fruits of his own labours: but as he was returning home from Seba's house on the evening of the 27th September 1735, the night being dark, he fell into the canal and was drowned. According to agreement, his manuscripts came into the hands of Linnæus, and his *Bibliotheca Ichthyologica* and *Philosophia Ichthyologica*, together with a life of the author, were published at Ledyen in the year 1738.

ARTEMIDORUS, a native of Ephesus, flourished, according to Reiff, in the reign of Marcus Aurelius. In his famous Treatise on the interpretation of Dreams (Ὀνειροκριτικά), he calls himself the *Daldian*, from Daldia or Daldis, the birthplace of his mother, by which name he is generally known, to distinguish him from Artemidorus the geographer, also a native of Ephesus. On this work he expended vast labour, not only possessing himself of all that had been written on the subject, but travelling for years in search of fortune-tellers, as well as corresponding with them in various parts, and collecting information on old dreams, and the events which were said to have followed them. It consists of five books, and contains some valuable observations on the maxims and customs of the ancients. The first edition is that of Aldus, 1518; the best that of Reiff, 2 vols. 8vo, Leipzig, 1805, with the notes of Rigault and Reiske. Artemidorus wrote also a treatise upon Auguries, and another upon Chiromancy, which are lost.

ARTEMIS, one of the chief divinities of Olympus, and worshipped under several forms in different parts of Greece and Asia Minor. The Ephesian Artemis was totally distinct from the Grecian goddess, and is supposed to have been originally an Asiatic divinity, the personification of the fructifying and all-nourishing powers of nature. The Romans identified Diana with the Greek Artemis. See DIANA.

ARTEMISIA, a queen of Caria, and daughter of Lygdamis, took part in person in the expedition of Xerxes against the Greeks, and distinguished herself in the sea-fight near Salamis, 480 B.C. She is said to have loved a young man named Dardanus, of Abydos; and enraged at his neglect of her, to have put out his eyes while he was asleep. The gods punished her for this, by increasing her passion; and having been advised by an oracle to go to Leucas, she is said to have taken the *lover's leap*, and to have been interred at that place. This part of her history, however, is probably fictitious.

ARTEMISIA, the sister and wife of Mausolus, king of Caria, immortalized herself by the honours which she paid to the memory of her husband. She built for him, in Halicarnassus, a very magnificent tomb, called the *Mausoleum*, which was one of the seven wonders of the world, and from which the title of *Mausoleum* was afterwards given to all tombs remarkable for their grandeur; but she died of regret and sorrow before it was finished. She appointed panegyrics to be made in honour of him, and proposed a prize of great value for the person who should compose the best. She died about 350 B.C.

ARTEMISIA, a botanical genus of the natural order of *Compositæ*; of which the best known are *A. Absinthium*, or wormwood, and *A. Abrotonum*, or southernwood.

ARTEMISIUM, in *Ancient Geography*, a promontory on the north-east of Eubœa (called *Leon* and *Cale Acte* by Ptolemy), memorable for the first sea engagements between the Greeks and Xerxes.

ARTEMON, a painter of antiquity, probably posterior to the time of Alexander the Great. Plin. xxxv. 11. There was also, in the first century after Christ, a sculptor of this name, who, with Pythodorus, adorned the palace of the Cæsars with statues. Plin. xxxvi. 5.

ARTEMON, a heretic of the second and third centuries, the founder of the sect called *Artemonites*, who applied philosophy and mathematics to the interpretation of Scripture.

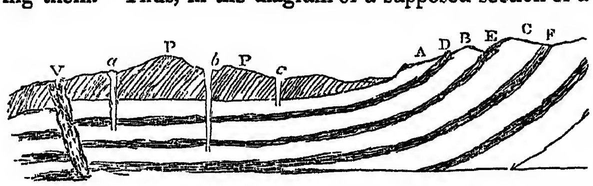
Artesian Wells.

They asserted that Christ was merely a prophet exalted by his virtues above all others, but denied his divinity. Euseb. *Hist. Ecc.* v. 28.

ARTESIAN WELLS, the name applied to artificial springs, produced by boring a small hole through strata destitute of water, into lower beds in which water is percolating in considerable quantity. On making such perforation, the water often rises forcibly to the surface, and is conveyed to a convenient receptacle by a pipe introduced by the perforation into the strata affording the water. The first place in Europe where such artificial fountains were extensively formed was in the French province of Artois, anciently *Artesium.* But there is reason to believe that the art was long before practised by the Chinese, who are very expert in the formation of such wells. They are extensively used in the Milanese, in several parts of Germany, and have also been for several years employed in the south of England, on the coast of Lincolnshire, and more lately in the vicinity of London.

An artesian well was sunk at Sheerness in 1781, to the depth of 330 feet (*Phil. Trans.* 1784). It was carried through a thick bed of *London clay*, and water, which rose nearly to the surface, was found on reaching the subjacent sand-beds. Two of better construction were carried to the same depth through similar materials at Portsmouth docks in 1828 and 1829.[1] The soil of the district on the coast of Lincoln between Lowth and the sea, rests on a thick bed of clay, which precludes the possibility of springs; but by penetrating through this, water was found in abundance in the chalk on which the clay reposed; and artesian wells there now afford a plentiful supply of this necessary element, that rises with such force through the pipes as to have obtained the local name of *blow-wells.*

The theory of artesian wells is founded on the fact that water derived from a higher level may percolate through certain strata, or pass in seams between them, and be prevented from reaching the surface by the superposition of other beds or strata impervious to water. In such circumstances a perforation through the latter allows the water, by hydrostatic pressure, to reach the surface; and it will overflow, or even gush out, with a force proportional to the difference of level of the different parts of the water-bearing strata, especially if the free course of the subterranean sheet of water be interrupted by what are termed *faults* in the strata, or the occurrence of veins of stony bodies intersecting them. Thus, in the diagram of a supposed section of a



country, let P P represent a thick bed of plastic clay, A B C strata affording water, alternating with strata D E F, impervious to water, and let V represent a vein of trap rock traversing these strata, and producing a *shift* or fault; by sinking the pipes a b c into the strata A B C respectively, we shall obtain the water derived from the more elevated portions of these strata at such artesian fountains.

The same principles are applicable to the sinking of common wells. It has sometimes happened that a well has been lost in attempts to increase its flow by a deeper excavation. Thus, if the bottom of the well was a bed of clay resting on sand, a perforation made through that clay has occasionally lost all the water; because the stratum of clay had prevented the water from escaping to a lower level, and conducted it towards the surface. The direction of the strata, as well as their nature, are essential elements for the successful formation of either common or artesian wells; which last are of great consequence in champaign countries, where natural springs are less common.

Artesian wells have been also sunk for the purpose of obtaining *warm* water. It is well ascertained that in the interior of our earth there is a source of heat, which may be reached by deep artesian perforations, so as to bring warm water to the surface. Thus Von Bruckmann of Würtemburg heated a paper manufactory at Heilbronn by water from a deep artesian well; and by the same means prevented the freezing of the water in winter round the wheels of mills. In the artesian well at Rochelle, at the depth of 370 feet, the water has a temperature 13° higher than that of the atmosphere. M. Arago was the chief promoter of the artesian well in the plain of Grenelle at Paris, which, at the depth of upwards of 1900 feet, affords water at 92° F. In the deepest artesian well yet made, that at Kissingen, the temperature of the water is also very considerable.

The instrument now used in making artesian perforations to great depths is not the old machine employed in boring for coal, &c., a series of iron rods screwed together, and forced down by repeated blows with a mallet. That was a costly and tedious operation: a Chinese instrument has lately been introduced with great effect. It consists of a heavy bar of cast iron, 6 feet long and 4 inches in diameter, armed at its lower end with a cutting chisel, surrounded by a cylindrical chamber, which, by means of simple valves, receives and retains the abraded portions of the rock. The instrument is suspended by a rope passing over a wheel. As it is wrought up and down, the torsion of the rope gives a circular movement to the bar of iron, sufficient to vary the position of the chisel at each stroke of the instrument; and when the chamber is full of the debris of the rock, it is drawn up and discharged. This mode of working has greatly diminished the labour and expense of such operations; and is applicable to many processes in mining, blasting in quarries, and the like.

An ingenious German engineer, M. Sellow, has by a similar instrument of greater size, succeeded in ventilating the mines at Saarbrück, by perforations 18 inches in diameter, and several hundred feet in depth.

The importance of artesian wells can scarcely be over-estimated. They are capable of rendering districts now scantily supplied with or destitute of potable water, convenient domiciles for man; and under an enlightened government might render habitable no small portions of the arid wastes of Africa and Arabia. In the latter, recent observations show that there are abundant subterranean sources of water, and possibly a series of artesian wells might diminish the perils of the passage of the Great Sahara.—See Hericat de Thury, *Considerations sur la cause du Jaillissement des Eaux des Puitsforés,* Paris, 1829; Von Bruckmann, *Ueber Artesische Brunnen,* Heilb. 1833; M. Arago, *Notices Scientifiques,—Annuaire du Bur. des Long. pour Annes plus.* (T. S. T.)

Artevelde.

ARTEVELDE, JAMES VAN, a brewer of Ghent, in the fourteenth century, who, by means of his enormous wealth and popular talents, acquired such an ascendancy over his countrymen that he was enabled to expel the Count of Flanders, and assume absolute power. He formed a commercial alliance with Edward III. of England, and persuaded the English to lend him assistance in his war with France. The French, however, prevailed; and Artevelde, who now began to dread the vengeance of the Count of Flanders, en-

1 The first artesian well in London was sunk in 1794. Examples of the same may be seen at the Bishop's palace at Fulham, and several in the town of Brentford.

deavoured to secure the interest of the English in his favour by transferring the sovereignty of Flanders to the Prince of Wales. This he attempted to effect by force; but the people beset his house and assassinated him. After this event, which took place in 1345, the Prince of Wales returned to England.

Philip Van Artevelde, son of the preceding, was raised to the sovereignty during a revolt of the people in 1382. He defeated the Count of Flanders, and obtained possession of Bruges; but, in November of the same year, he was defeated and slain by the count, assisted by the French, in a battle fought near Rosbecq, and his body was ignominiously hung on a tree.

ARTHRITIC, a term applied by physicians, in a restricted sense, to painful affections of the joints arising from gout. The word is derived from αρθρον, a joint.

ARTHUR, the celebrated hero of the Britons, is said to have been the son of Uthor Pendragon, king of Britain, by Igerne, the wife of the Duke of Cornwall, and to have been born in 501. His life is a continued series of wonders. It is said that he killed 470 Saxons with his own hand in one day; and, after having subdued many mighty nations, and instituted the order of the Knights of the Round Table, died A. D. 542, of wounds which he received in battle. The most particular detail of his story and his exploits is that given by Geoffroy of Monmouth; but there the probable is so blended with the marvellous and extravagant, that not only the truth of the whole, but even the reality of Arthur's existence, has been called in question. In this controversy Mr Whittaker has taken much pains, in his *History of Manchester*, to vindicate the existence, and discriminate between the real and the fabulous transactions, of the British worthy. But a severe critic might be apt to say that it requires much faith in the author's judgment, not to suspect that he sometimes allows too much scope to fancy and conjecture. According to Mr Whittaker, Arthur's principal exploits were against the northern Saxons, whilst he was only prince of the Silures, and Ambrosius was the dictator or pendragon of the Britons. "In a series probably of five campaigns, and in a succession certainly of eleven victories, this great commander had repelled the Saxons from the north of Flavia, dislodged them from all Maxima, and dispossessed them of all Valentia. And these were successes so unchequered with misfortunes, so great in themselves, and so beneficial to the public, that the name of Arthur claims the first rank in the list of military, and the better one of patriot, heroes." The twelfth battle of Arthur was fought in the south of England, after he was elected to the pendragonship, against Cerdic the Saxon. "This," says Mr Whittaker, "was a most extraordinary victory, and completes the circle of Arthur's military glories." In the author's account of this prince's conduct in peace, he asserts, that "Arthur saw that an appointment was wanted, which should at once be a more regular and more honourable signature of merit—by the certainty of the honour and the greatness of the dignity, call out all the worth of all the worthy in the nation, and collect it round the throne of the pendragon. Accordingly he established a military order. It was the first that had ever been instituted in the island; and it has since been imitated by all the nations on the Continent. By means of this association, Arthur raised among the provincials a general glow of ingenuous heroism, the first spirit of chivalry that ever appeared in Europe; that manly and honourable gallantry of soul, which has made him and his worthies the subject of romantic histories over all the west of it. By this, and this alone, could he have been what history represents him, the Revered Father of the British Heroes in general, even to the conclusion of the sixth century, and nearly the middle of the seventh. The order naturally survived its founder; and the members of it were denominated the Warriors of Arthur, though the persons were born half a century after his death."—See also Sharon Turner's *History of the Anglo-Saxons.*

Arthur's Round Table, a round enclosure near Penrith, on the banks of the streamlet Loder. It is formed by a ditch and rampart of earth, 29 yards in diameter and is supposed to be an ancient place for tilting.—See Pennant's *Scottish Tour*, vol. i. p 277.

Arthur's Seat, a hill in the immediate vicinity of Edinburgh, said to have been so called from a tradition that King Arthur surveyed the country from its summit, and also defeated the Saxons in its neighbourhood. It rises by a steep ascent till it terminates in a rocky point, 822 feet three inches above high-water mark at Leith, as given by Moffat in his Levels of Edinburgh. From its summit the traveller may survey the centre of the kingdom, and obtain a complete view of Edinburgh, the whole forming a landscape varied and beautiful in a very high degree. Its rocky summit has some curious magnetical properties.

ARTICLE, in *Grammar*. See GRAMMAR.

ARTICULATA, Cuvier's third great division of the animal kingdom; including *Crustacea, Arachnides, Millipeds* or *myriapods*, and *Insects*, all which were comprehended by Linnæus under *Insecta.*

ARTIFICER, a person who works in iron, brass, wood, &c., such as smiths, brasiers, carpenters, &c. The Roman artificers had their peculiar temples, where they assembled and chose their own patron to defend their causes; and they were exempted from all personal services. Taruntenus Paternus reckons 32 species of artificers, and Constantine 35, who enjoyed this privilege. The artificers were incorporated into divers colleges or companies, each of which had their tutelar gods, to whom they offered their worship. Several of these, when they quitted their profession, hung up their tools, as votive offerings to their gods. Artificers were held a degree below merchants and *argentarii* or money-changers, and their employment more sordid. Some deny that in the earliest ages of the Roman state artificers were ranked in the number of citizens; others, who assert their citizenship, allow that they were held in contempt, as being unfit for war, and so poor that they could scarcely pay any taxes; for which reason they were not entered among the citizens in the censor's books; the design of the census being only to see what number of persons were yearly fit to bear arms and to pay taxes towards the support of the state. It may be added, that much of the artificers' business at Rome was done by slaves and foreigners.

ARTIFICIAL HORIZON, a contrivance of great utility for enabling an observer to determine the altitude of a heavenly body, or of a terrestrial object, above the horizon of any place, when the sensible horizon is ill defined. The surface of a fluid not easily disturbed by the air, such as quicksilver, or some viscid, opaque fluid, is usually employed for this purpose, as they will adjust themselves to a plane parallel to the rational horizon. To prevent the influence of winds in the open air, the surface is usually covered by a plate of ground-glass with parallel surfaces. In fixed observations this is not necessary; and the mercury is contained in an oblong trough: for locomotive observations, a cup of three inches in diameter is the containing vessel. But as carrying about mercury is inconvenient, some have employed polished metallic or glass mirrors, adjusted by screws at the corners, and a spirit-level, to horizontality; though this is less accurate than the fluid surface. The surface of the quicksilver, or mirror so adjusted, is a plane touching the surface of the earth where the observation is made, and parallel to the rational horizon; therefore, a ray of light passing from the object to the surface of the instrument, forms an angle with that surface equal to the angular elevation of that object above the true horizon of the place, when it is corrected for parallax and refraction.

ARTILLERY.

The term artillery, in modern warfare, is applied, in a special sense, to those projectile machines which, from their magnitude and weight, cannot be made the personal weapons of a soldier; and, in a general sense, to the officers and men, that is to say, to the *personnel* as well as to the *materiel* of that branch of the army to which the care and management of such machines have been confided. The origin of artillery, in the modern and special meaning of the term, may be simply ascribed to the substitution of a chemical for a mechanical agency in the projection of missiles of war; and the great superiority of modern artillery depends on the power of conferring great velocities on the bodies to be moved, by the sudden development of gaseous bodies from materials previously in a solid form. Notwithstanding the great improvements in modern machinery, it may be safely assumed, that by no application of the property of elasticity in metallic, wooden, or other springs, could a convenient machine have been formed to propel a 32-pound shot with a velocity of 1600 feet per second, although it is highly probable that one might have been constructed to propel very large masses with a low velocity, or to produce great momenta, as was in fact the case with some of the projectile machines of the ancients. Gunpowder, or the chemical agent now used in propelling warlike missiles, is a compound of nitre, charcoal, and sulphur, three substances which, under ordinary circumstances, retain the solid form, although intimately mixed together and in contact with each other. By the application of heat amounting to about 570° of Fahrenheit, by the electric spark, or by the shock between the bodies, and that not merely of iron against flint or other very hard body, but even of copper against copper, iron against marble, lead against iron or lead, provided the force of the shock be sufficient to develop the required amount of heat, the chemical affinities between the elements of these solid substances are excited; and they are almost instantaneously transformed into gaseous bodies in a state of great compression, and therefore endowed with an enormous elastic force. This chemical change is also accompanied with a great development of heat, which further tends to expand the gases; so that, at the moment of ignition, if considered instantaneous, the gases produced would be capable of expanding to a bulk 2000 times greater than the original volume of the gunpowder, or at that moment would exercise a force capable of reducing 2000 volumes to one. Such a force, if really exerted at its maximum of intensity, would require an enormous thickness, and therefore weight of metal, to resist its expansive effect; but the ignition of gunpowder, however rapid, is not instantaneous, and the ball, therefore, is put into motion, and the resistance of the air overcome before the perfect development of the gigantic power which is thus called into action.

In gunpowder, viewed theoretically, nitrate of potash, nitre, or saltpetre, is the reservoir of oxygen; charcoal, the element which, by its combination with oxygen, should form the gaseous body carbonic acid; and sulphur, the element which should facilitate ignition, and, by its affinity for the metallic base of potash, potassium, assist in inducing the decomposition of the nitre. The chemical formula which represents a compound which after ignition should yield only sulphuret of potassium, carbonic acid, and nitrogen, is $KONO^5 + 3\,C + S$, or, nearly, nitre 74·75, charcoal 13·34, sulphur 11·87; and though the gaseous product might be increased in volume by introducing sufficient carbon to produce carbonic oxide instead of carbonic acid, the gain in volume would be more than counterbalanced by the loss of heat.

The gunpowder of various nations approximates more or less to this normal composition.

England,...	*Nitre*	75·00	*Charcoal*	15·00	*Sulphur*	10·00
France, ...		75·00	...	12·50	...	12·50
Russia.		73·78	...	13·59	...	12·63
Austria, ...		76·00	...	11·50	...	12·50
Spain, ...		76·47	...	10·78	...	12·75

China, ...		75·00	...	14·40	...	9·60

It must not, however, be imagined that the result of ignition is exactly that which, from the theoretical formula, should be expected, as the products of combustion are more varied, and include, in addition to sulphuret of potassium, carbonic acid and nitrogen, portions of carbonic oxide, sulphuretted hydrogen, carburetted hydrogen, sulphide of carbon, sulphate and carbonate of potash, cyanide of potassium, and vapour of water; these products being the results of progressive, and therefore partial, ignition and decomposition. According to Dr Ure, the gaseous products of the combustion of gunpowder are carbonic oxide, sulphurous acid, and nitrogen; and there can be no doubt that the comparatively imperfect operation of chemical affinities between the particles of its solid constituents has a tendency to introduce more or less of sulphurous acid into the results by the direct combustion of the sulphur. Some of the modifications in the composition of gunpowder adopted by various countries have most probably been directed to a correction of this evil, as both sulphurous acid and sulphuretted hydrogen exert an injurious action on the metal of guns, more especially on that of bronze guns. As general rules, however, the sulphur must not be much less than the quantity of the theoretic formula, as, if so, the rapidity of ignition, and the amount of heat will be diminished; nor must it be much more, as, if so, the production of sulphurous acid will be increased, and with it the destructive effects on the gun; and in like manner the charcoal must not be much less, as, if so, there will be a defect of carbon for forming either carbonic acid or carbonic oxide; nor much more, as the gunpowder would, in addition to other defects, be thereby made too highly absorbent of moisture. When first made, gunpowder is in the state of fine dust, which is called meal powder, but as it is then liable to cake, and from the close packing together of its grains the rapid transmission of flame would be checked, the powder is granulated under a moderate force of compression, by which the grains acquire a greater density; and this quality being aided by glazing, they retain more effectually their form, and in some measure resist moisture, whilst the passage of flame through an assemblage of such grains is comparatively easy. Nothing but experience and practice can enable the manufacturer to decide the exact amount of compression or degree of glazing, as any material excess must injure the quality of the powder, by diminishing its combustibility.

The knowledge of an explosive force equivalent, according to Professor Graham, to at least 1000 atmospheres, and the power of readily applying it to practical uses, must very soon have led to important changes in the machines of war; and it might therefore have been expected that the exact epoch of its first employment would have been easily discovered. Such, however, is not the case, and there is still considerable uncertainty in the histories of gunpowder and of cannon. Colonel Chesney has most ably followed up the researches of M. Reinaud and M. Favé on the Greek fire of the ancients, and done much to establish the correctness of their opinion, that compounds of nitre were used at a very remote epoch, not merely for ignition, but also for explosion and propulsion. Passing over the earlier instances of the mention of "incendiary projectiles," amongst the natives of China and Hindustan, Colonel Chesney, quoting the fol-

lowing passage from Chased, a Hindu bard:—"Oh! chief of Gajné, buckle on your armour, and prepare your fire-machines;" the meaning of which is explained in a following stanza, in which the bard states "that the culivers and cannons made a loud report when they were fired off, and the noise of the ball was heard at the distance of 10 coss, or nearly 1445 yards," concludes from it "that the fact of cannon balls having been propelled by means of gunpowder in India as early as A.D. 1200, the epoch of the poet, appears to be established, although the use of artillery is not mentioned by any European writer before the fourteenth century." There is no reason to believe that this was the first, or even a very early instance of the use of such projectiles in the East; and it must therefore be considered highly probable that both the knowledge and the use of the explosive properties of compounds of nitre with charcoal and sulphur were of remote origin in a country which yields as a natural product, even to this day, so large a quantity of this important military mineral. Piobert, Napoleon Buonaparte, and other writers, have collected much information on the appearance and progress of artillery in Europe; but it is satisfactory to quote such examples from the work[1] of an English officer of artillery, so highly distinguished as Colonel Chesney, who has shed so much lustre on his profession by the intrepid zeal and persevering energy of his Euphrates expedition, and his great literary and scientific acquirements. "The Moors, according to Condé, used artillery against Zaragossa in 1118; and in 1132 a culverin of 4 lb. calibre, named Salamonica, was made. In 1157, when the Spaniards took Niebla, the Moors defended themselves by machines which threw darts and stones by means of fire; and in 1156 Abd'almumen, the Moorish king, captured Mohadia, a fortified city near Bona, from the Sicilians by the same means. In 1280 artillery was used against Cordova; and in 1306 or 1308 Ferdinand IV. took Gibraltar from the Moors by means of artillery. Ibn Nason ben Bia, of Grenada, mentions that guns were adopted from the Moors, and used in Spain in the twelfth century, and that balls of iron were thrown by means of fire in 1331. These, and other examples, render it almost certain that the use of gunpowder became first known in Europe through the Moorish conquests and warfare in Spain, although the true components of gunpowder were known to Friar Bacon, and were made generally known throughout Europe by Bartholdus Schwartz in 1320. Edward III. of England used 'crakeys of war' during his campaign against the Scots in 1327. In 1339 ten cannons were prepared for the siege of Cambray by the Chevalier Cardaillac. Quesnoy was defended successfully in 1340 by cannon which flung large iron bolts. In 1343 the Moorish garrison of Algesiras, besieged by Alphonsus XI. of Castile, used long mortars, or troughs of iron which threw among their enemies thunderbolts. In 1346, an iron gun, with a square bore capable of projecting a cubical iron shot of 11 lb. weight was constructed at Bruges. In 1346 Edward III. is said to have used artillery at the battle of Cressy; but this is very doubtful, as the application of guns to field operations appears to be of later date, and no notice of them at the subsequent battle of Poictiers can be traced. In 1347 Edward did, however, use artillery in the siege of Calais, as did the Prince of Wales in 1356 in reducing the Castle of Romozantin. In 1378 Richard II. employed 400 cannons, which fired day and night, in his unsuccessful attack on St Malo; but it is unnecessary to follow further the progress of this most important arm in the attack and defence of fortified places and positions. The French, in the latter portion of the fifteenth century replaced the old cumbrous bombards by brass guns with trunnions, and the heavy stone shot by metal balls; and as the results of these changes were rapid firing and an increased impetus of shot, artillery may then be said to have first become really effective. Though portable guns had been occasionally made, from the earlier half of the fourteenth century, and had been abundantly applied in the wars of the fifteenth, they do not appear to have been reduced to a perfect system of field artillery until the reigns of Charles VIII. and Louis XII., and in 1500 the latter monarch was able to move his artillery from Pisa to Rome, a distance of about 240 miles, in five days, and possessed light pieces which were sufficiently manageable to be taken rapidly from one point to another during a battle. When he recovered Genoa in 1507, he had 60 guns of large calibre for an army of about 20,000 men, and overcame the Venetians on the Adda in 1509 by means of his artillery. Francis I. adopted a lighter construction for field-guns, and had them drawn by the best description of horses." In the defeat of the Swiss at Marignan in 1515, "the French artillery played a new and distinguished part, not only by protecting the centre of the army from the charges of the Swiss phalanxes, and causing them excessive loss, but also by rapidly taking such positions from time to time during the battle as enabled the guns to play upon the flanks of the attacking columns." These extracts, which have been principally derived by Colonel Chesney from the celebrated work of the present French emperor, who, like his illustrious uncle, was an artillery officer, go far to prove that, though the French have no right to claim the invention or even the material improvement of the bastion system in fortification, which was manifestly the work of Italian engineers, they have great reason to claim the first establishment of an efficient field artillery. In 1631 the great Gustavus Adolphus was indebted in great part to his artillery for the victory of Leipzig; and some of his guns were of the remarkable description called cannons of boiled leather, which "consisted of a thin cylinder of beaten copper screwed into a brass breech, whose chamber was strengthened by four bands of iron; the tube itself being covered with layers of mastic, over which cords were rolled firmly round its whole length, and equalized by a layer of plaster, a coating of leather boiled and varnished completing the piece." The carriage and the piece were so light that two men were sufficient to draw and serve the gun, which, however, could bear only a small charge. In the battle of Lutzen, when this truly great warrior, for he was a Christian warrior, closed in death his short but brilliant career, the Swedish artillery was again remarkable for the ease with which it was manœuvred and shifted in position, whilst the less manageable cannon of the Imperialists were comparatively immovable. Colonel Chesney observes, in respect to these two great and glorious battles of the Swedes, that they prove that the artillery of Gustavus Adolphus, although still consisting of too many calibres, was admirably organized, embracing as it did limbers, and carrying cannister shot, and other kinds of ammunition, ready for action; and that this distinguished commander was the first who fully appreciated the importance of causing the artillery to act in concentrated masses. Frederick the Great of Prussia further improved upon the system by introducing pieces of ordnance sufficiently light to take part in the most rapid manœuvres; and since that time it has been admitted by most military men that guns intended to move with an army and take part in field operations, should be divided into two sections, namely: 1st, Guns sufficiently light to move with cavalry, and hence forming what is called in the British service Horse Artillery or *Cavalry Artillery;* 2d, Guns of larger calibre and greater weight than the former, to act with infantry, but still not too heavy to allow of considerable rapidity in all the changes of position which may be required on the field of battle. These constitute what are called field batteries.

[1] *Observations on Fire-Arms*, 1852.

The great improvement of the field batteries of the British army, and the superior horses attached to them on home service, have led many able English artillerists to imagine that the distinction between the field battery and the horse or flying battery is unnecessary, and that the former may be readily brought up in speed and efficiency, even when acting with cavalry, to the latter; but it is probable that this opinion has been formed more upon the results of field days on a favourable review ground, than on the experience of practice and movement on irregular ground such as must always be met with in actual war; and has been adopted without reference to the importance of securing for the field batteries, which must frequently be required to act as artillery of position in field works, the largest calibre compatible with a reasonable facility of movement. When this subject has been more fully considered and tested by experiments, more assimilated to the varied movements of war, it is believed that the value of the horse artillery will be better appreciated, and steps taken to render it still more effective by actual experience in war, for which the East Indian service, ever pregnant with events of war, is always open. The horse artillery is indeed too valuable a branch of this most important arm to be allowed to remain idle, or to be looked upon as a mere appendage to military shows. In like manner, such considerations would probably lead to the adoption of the 12-pounder on the other branch, rather than to any further attempts to increase the speed of field batteries, or to make them rival the horse artillery in rapidity of movement.

The difference between the rude guns of early times—formed with iron bars fitted together lengthwise, and secured by iron rings—and the well-proportioned iron or bronze guns of modern times, is assuredly very great; but there can be no doubt that artillery will yet be much more improved and its range increased so as to secure for it that superiority of range over the improved musket which it has hitherto possessed over the old musket.

By the adoption of artillery, the mode of application of propellent weapons has been changed, but not the principles. In war there has always been two forms of offensive action, namely, that carried on at a distance, and that conducted foot to foot or at close quarters; and the object of the first has always been to prepare for the second. The operation, therefore, of any means of offence is analogous to that of artillery. Archelaus[1] arranged his order of battle against the Roman general Sylla in the following manner:—In front he placed chariots armed with scythes, for the purpose of making an impression on his enemy's line; in the second, the Macedonian phalanx for attack; in the third, the armed auxiliaries as a reserve; and in a fourth the light troops, to be able to deploy and skirmish in every direction, whilst his numerous cavalry occupied both wings or flanks of the army. To meet this array, Sylla strengthened his position by wide trenches, defended by forts on his flanks, so as to prevent the enemy from outflanking and taking him in reverse with his numerous cavalry; and having thus restricted the attack within the limits of his centre, he arranged his foot in three lines, broken by intervals for the ready movement of the light troops and of the horse, which, being only a small body, was held back in readiness for a decisive charge at the right moment. Sylla further ordered a portion of his troops to drive palisades into the ground, between which the charge of the armed chariots could be awaited with little risk; and then, as the chariots advanced, they were received with loud shouts, and with showers of darts from the light troops, which threw them into such confusion that they turned and carried alarm into the ranks of the Macedonian phalanx, which beginning to yield, was for a moment supported by the cavalry of Archelaus, when the Roman cavalry suddenly charged, and won the victory. In this battle the armed chariots were intended to perform the office of artillery by first breaking the Roman line before the advance of the Macedonian phalanx; and in like manner, on the Roman side, the darts were propelled in the manner of artillery on the advancing troops. The comparatively small range of darts, arrows, or the bolts of cross-bows, limited the effect of their action so much, that though it was often very destructive when directed on an enemy who was obliged to retain his position, it was soon abated when an enemy was able to advance, or so reduced that its effect corresponded to that of the fire of light infantry. The case is very different with modern artillery, as their fire, commencing at a considerable distance, will continue to be destructive, even on an advancing force, for a considerable time. The objects, however, both of ancient and modern artillery are the same, namely, to make an impression on an enemy's line, and to disturb the stability of its masses before the last effort is made by a charge to overthrow it; and in like manner to break and paralyze an advancing column, so that its shock may be weakened or rendered comparatively harmless; and these objects ought therefore to be kept in view in the distribution and arrangement of artillery.

The value of any system of field artillery may be readily estimated by reference to its efficiency for producing the desired results which have been explained. For example, in the early period of British artillery, guns were allotted to each regiment or battalion as battalion guns; but though this arrangement was so far correct, as it rested on the principle that every body of troops capable of independent action should be accompanied in the field by artillery, it was erroneous when applied to large armies, as it spread the artillery through the line, and caused it to act either against artillery, producing a mere war of guns, or against infantry at so many points as to produce no decided effect at any. It is true, indeed, that such battalion artillery might have been separated, when necessary, from their battalions, and brigaded together; but it is manifest that the movements of an aggregate of so many separate elements which had not been previously trained to act together, must have been rude, uncertain, and very difficult of control: whilst the natural and simple mode of rectifying an arrangement so defective would have been the adoption of a combination of guns based upon some element or unit which represented the least number of guns deemed capable of acting with effect in co-operation with infantry.

To determine the unit or element of battery combination, it should be remembered that the principles of defence by artillery are the same, whether the guns act openly in the field, or covertly from behind a parapet, and that the object should be in either case to secure a cross, converging, or concentrated fire on the line or column of attack, or in front of the point to be attacked. A flanking fire is therefore as essential to an army in the field as it is in a fortress; in which latter case it may be justly said, that perfection depends even more on the efficiency and right arrangement of its active defences than on the solidity and permanence of the passive; as no walls of stone or of earth can be expected to stop an enterprising enemy, unless supported by a well-directed and steadily maintained fire. To obtain such a flanking and cross fire for the smallest number of troops likely to act independently, one gun on each flank or wing is the least possible number; and hence two guns may be deemed the elementary unit of battery combination; the term battery being applied primarily to a number of guns acting together, and secondarily, to the works of defence, or parapet, thrown up to cover them. In most of the armies

[1] *Strategematicon S. Julii Frontini.*

of the present day this principle has been acted upon; and the unit having been fixed (on an average) in relation to a body of 800 men (omitting cavalry, the action of which is propulsive or analogous to that of artillery), or of 1000 men, including cavalry, the strength of a simple field battery has been made some multiple of that unit; as, for example, exclusive of howitzers, in France, 4; Bavaria, 6: Sweden, 6; Spain, 6; Holland, 8 and 6; Wurtemberg, 6; Prussia, 6; Russia, 6; Austria, 6; or, taking howitzers into consideration, in France, 6; Bavaria, 8; Sweden, 8; Holland, 8; Wurtemberg, 8; Prussia, 8; Russia, 8; Austria, 8; two howitzers having been in each case apportioned to a battery; so that, when required to be subdivided for action on the flanks of the infantry to which it is attached, each half-battery may be provided with one howitzer. In the British artillery this latter principle has not been attended to; and though the combined battery consists of six pieces, 5 are guns, and 1 a howitzer, not therefore admitting of exact division of either. The duke of Wellington appears to have been sensible of this defect in principle, as he suggested the increase of the number to 8, that is, to 6 guns and 2 howitzers, which would have assimilated the British to the Prussian, Russian, and Austrian artillery, in respect to the strength of its field batteries; the number of howitzers being one-fourth of the whole, rather than one-third, as in the French, which appears excessive.

In conforming to the necessity of so arranging artillery as to ensure a flanking defence, either to the line of troops, or to the position exposed to attack, it must of course be kept in view that the effective range of field battery guns will limit the extent of the line or position to be thus defended; and, therefore, that in long lines as many batteries must be interposed between the flanks as will ensure to each section of the whole line a sufficient artillery defence; or else that there shall be a facility of bringing up rapidly the required guns to the flanks of the actual portion of the line exposed to attack, and at once concentrating a heavy fire upon the ground in front of it. These considerations, as well as the similar necessity of supporting the movements of an attacking column by the fire of artillery on the point of the line to be attacked, and the changes which it may be found expedient to make during a battle in respect to that point, have made it manifest that artillery, to be really useful in the field, must not be too heavy; and, in consequence, the guns of field batteries (properly so called) of all European nations are now comprised between the 6 and the 12-pounder, exclusive of the still lighter ordnance for mountain service. Marshal Marmont[1] observes,—"Field artillery is required to follow the troops in all their movements, and to arrive at any given point with promptitude, so as to crush an enemy. It should therefore be light, easily transported, and so handy as to be stopped by no impediment of ground. The 6-pounder, in use throughout Europe, appears to me sufficient; it was the calibre I adopted when at the head of the French artillery; and it was that with which the wars of the empire were waged. A calibre of eight has now been adopted; and though, without doubt, its superior weight has advantages, it has the great inconvenience of increasing by one-third the weight of ammunition and stores, and of requiring more powerful means of transport, which in a war it is difficult to provide." In addition, however, to these calibres, Marmont recommends the 12-pounder as necessary in silencing the fire of an enemy's field works, in arming such works, in battering down simple walls, or in defending the passage of rivers, and even suggests a small proportion of short 24-pounders intended to be fired with diminished charges. Such are the pieces which a general so experienced in war recommends for field artillery, and the objects he assigns to each are manifestly those which must be comprised within the scope of a well-considered establishment. The calibres he names are in English weights equivalent nearly to $6\frac{1}{2}$, $8\frac{5}{8}$, 13 lb.; so that, on an average, they correspond very closely with those adopted in the British service; but though there is much to say in support of this view of the subject, and specially in favour of the lighter calibre, as possessing such facility of movement, it is time to inquire what influence is likely to be exercised on field artillery in action by the improved musket of the present day. In considering this question, it is right to remember that, whilst it is the office of artillery to act against infantry, and to prepare the way by the disturbing effects of its fire for the ultimate shock or bayonet charge, so is it the office of tirailleurs or riflemen to act against artillery, and check or even paralyze its fire. Lieutenant-Colonel the Hon. A. Gordon, in his recent work addressed to the volunteers,[2] states that "the French have not yet adopted any of the new systems (except for trial in a few special corps), nor have they, from what I can learn, any intention of doing so;" and this caution, on the part of men so fully acquainted with military science, ought to be ascribed to the real cause, namely, a conviction, as Lieutenant-Colonel Gordon observes, that the ordinary soldier, from the skill of his commander in manœuvring, and the selection of positions, will not be exposed to an enemy's fire, or at least kept standing so exposed at a great distance; and that the full advantage of muskets or rifles, which are capable of shooting with accuracy up to a range of 800 yards, can be only looked for when they are placed in the hands of men of more than ordinary nerve, coolness, activity, and skill. Napoleon, who above all generals understood the importance of a right application of artillery in the field, and who in consequence employed his guns in masses so as to concentrate upon any one point an overwhelming discharge, was also fully sensible of the services to be derived from efficient tirailleurs or riflemen in checking the fire of artillery, and that more especially when the guns were assembled together in powerful batteries. He also knew well how to use riflemen occasionally as artillery, either by directing their fire against ordinary infantry at the point to be attacked, or as a means of protecting the movements of other troops; as, for example, in the campaign of 1807, when his first bridge over the Danube was constructed under the protection of his battalions of tirailleurs, who swept the island of Lobau with their fire.

During the campaigns of Napoleon and Wellington, the rifleman was armed with a weapon possessing only a very limited range and comparatively slow in loading; but had it been otherwise, and had he possessed the modern rifle musket, which unites rapidity and precision of fire with a long range, can it be doubted that some of the most brilliant movements even of that distinguished artillery officer General Senarmont would have been impossible. On the 29th January 1807, the corps d'armée of Marshal Augereau advanced on Eylau, and took up a position in rear of that town. Senarmont at first posted the artillery of the first division, consisting of eight 8-pounders, two 4-pounders, and two howitzers on an elevated knoll; but finding that, from this exposed situation, the battery became the mark of all the enemy's batteries, arranged as they were in a line concave towards the French, and was soon, therefore, greatly cut up, he determined to move forward to some flat ground in front on a lower level, whilst the artillery of the second division took up their first position in order to divide the attack of the enemy. These two batteries were in line, and swept the space between the two armies, so that the Russian infantry and cavalry, as they successively advanced to the charge, were mowed down by the fire of the 19 combined

[1] *Esprit des Institutions Militaires.*

[2] *Remarks on National Defence*, 1853.

guns. The nearest of these batteries was about 450 yards from the Russian line, and though then tolerably secure from all but the fire of artillery, what would have been its condition had the Russians possessed the modern musket, and been able to pick off every man and every horse from a distance of 600 or even 800 yards? Again, at the battle of Friedland, June 1807, the French had suffered so much from the fire of the Russian battery on the opposite bank of the Alle, that the troops began to waver, when Senarmont collected together 36 guns from several divisions and brought them up with great rapidity to an eminence about 450 yards from the enemy, and after a few discharges pushed on to another point at only 230 yards from the Russians, when the rapid and well-directed discharge of 36 guns soon silenced the small detached batteries of the Russians, and being then turned upon the closely-packed masses of the infantry, spread destruction and confusion amongst them. The successful issue of this battle is ascribed by General Marion, the biographer of Senarmont, to the admirable manner in which that officer handled the artillery. "It was due," he says, "to the admirable feat of arms of General Senarmont, and the artillery cannot cite one more glorious. Thirty-six pieces of artillery did what Ney and Dupont with more than 20,000 men had been unable to do, and what the three reserve divisions of Victor would probably not have done. Looking at the steady courage with which the Russians, when their retreat had been cut off, resisted the attacks of the triumphant army, it may be well assumed that victory would have been impossible to any other arm than artillery; but Senarmont advanced his guns and obtained the most brilliant success." In this case the artillery acted almost as an independent body, and bold and successful as the manœuvre was, it may be fairly stated that under present circumstances the repetition of such an act of daring would be attended with the utmost peril.

If the object were to bring into one general point of view the importance of the artillery arm, as illustrated by its achievements in modern wars, numerous examples might be brought forward from the annals of the British army, both in its European and Indian branches, as well as from the exploits of the French and other armies; but at present those cited will be sufficient to point out the peculiar circumstances under which artillery have acted with overwhelming effect, and to suggest the controlling influence which must henceforth be exercised over its movements under similar circumstances. Nor is positive experience wanting on the present state of the question, as the Prussian needle gun was actually in use during the recent contests of the Prussians and Danes; and according to an eye-witness (Lieutenant-Colonel Stevens, Royal Marine Artillery), was the instrument by which the Danish artillery was effectually kept in check even at the distance of 800 yards. Such considerations should impress upon the military authorities the necessity of directing their attention to the following points:—

1*st*, The employment of the largest calibre which is consistent with a due degree of celerity of motion.

2*d*, The propriety of having 6-pounder batteries for the horse or cavalry brigade, 9-pounder batteries for the ordinary infantry or moving brigade, and 12-pounder batteries for position and reserve.

3*d*, The attainment of perfection in the use of spherical case as applicable to ranges beyond the effective fire of the new rifled musket, and the more general use of this excellent projectile.

4*th*, The formation of howitzer batteries, so as to use the largest possible shell which can be attained without an inordinate increase of weight in the gun, and yet to retain a sufficiency of range.

5*th*, To cover the artillery when possible with light entrenchments, sufficiently thick to secure the men from musketry fire, and yet such as can be rapidly opened at the crest for the guns to fire over or through.

6*th*, The improvement of rockets, and the extension of their use as auxiliaries to guns.

7*th*, The combined operation of artillery and riflemen.

8*th*, The still further extension of the principles of ordinary field-work defence to the use of artillery, by a system of supporting or flanking batteries intended to scour the ground in front of those batteries which require to be advanced in order to produce a decided effect on an enemy's line. Such a service could only be done effectually by spherical case, and therefore might be confided to howitzers.

In point of general organization, it may without hesitation be assumed, that the British artillery stands in the first rank of excellence, and yet the improvements which have raised it to a state of such perfection are the work of the present age. At the commencement of the war in 1793, the various ordnance equipments, as well as the whole composition of this branch of our military service, were of the rudest kind, and on the worst organized and most defective plan. The inefficiency of the whole system, indeed, was palpably betrayed whenever a force was required to take the field. The guns being dispersed among the infantry, at the rate of two pieces to a battalion, it was impracticable to employ them for their legitimate purpose of concentrating a powerful fire of numerous guns on any important point. They were also horsed in single team, which needlessly both lengthened the column of march and diminished the power of draught. The drivers were on foot with long whips, as were also the gunners. The ammunition was packed in large rough deal boxes; the waggons which conveyed it were heavy and ill-constructed; and the whole equipment was so cumbrous, that it was impossible for the train to move out of a foot-pace, except for a very short distance; and if increased speed were attempted before the enemy, the men came into action breathless and unable to serve their guns.[1]

But before the commencement of the Peninsular war, that active and able officer, the late Major Spearman, had entirely re-organized this branch of the service; and it is to him that the country owes the present beautiful system of field artillery. The battalion guns were abolished, and the artillery was brigaded, distinct from the infantry and cavalry with which it served, in divisions of six pieces each; so that the fire of one or more of these powerful batteries could be readily concentrated on any given point. A body of military drivers was organized, while, by an ingenious contrivance of the shafts, the power of using single draught in narrow roads, or when any of the horses were disabled, was retained. The drivers were mounted on the near horses; and the gunners themselves, in the proportion of eight to each piece, were carried on the limbers and ammunition cars. The whole of the equipment was simplified and lightened to such a degree that the batteries could move at a gallop; the ammunition, packed in boxes on the limbers and cars, was always up with the guns; and the officers and men, being all mounted or conveyed on the carriages, were sure of being brought fresh into action. Finally, a system of manœuvres for artillery in the field was introduced, which gave order and precision to their own movements, and established uniformity between them and the troops of other arms.[2]

Such was the general condition in which the artillery was

[1] *British Gunner.*

[2] *Ibid.*

Field Artillery.

then placed, and it may be fairly stated that no pains have been spared by those subsequently in authority to improve its details and increase its efficiency. Of this arm the cavalry artillery branch is in the British service more especially a horse artillery, as so many of its men are carried on horseback; whereas, in the Austrian service, the men are carried on light spring waggons. The respective merits of these two systems require to be more fully investigated, and no prejudice in favour of our own system, which is certainly the more brilliant in appearance on a field-day, should be allowed to prevent its rejection, if found on comparison inferior. The British system involves the care of a larger number of horses both in the field and in camp, and hence greater trouble and anxiety to the men; the Austrian, the chance of having the locomotive power of the whole gun detachment crippled by the destruction or injury of a single waggon. In respect merely to comparative speed, it is probable that a light spring waggon would be fully able to keep pace with the guns, and to move over any ground practicable for them.

To secure the successful employment of an artillery force, it is necessary that the whole body should be carefully trained, and that the objects to be attended to should be fully understood. General Lewis has therefore exhibited the subjects of artillery in a very simple form,[1] which, with a slight modification, is here given:—

- *Personnel*
  - Horse artillery.
  - Rocket do.
  - Foot do.
    - Field.
    - Garrison.
  - Invalid gunners.
  - Master gunners.
- *Materiel*
  - Ordnance
    - Iron
      - Guns.
      - Howitzers.
      - Mortars.
      - Carronades.
    - Brass
      - Field guns.
      - Field howitzers.
      - Mortars.
    - Rocket
      - Field.
      - Heavy.
  - Carriages
    - Travelling
      - Field.
      - Siege.
    - Standing
      - Wood.
      - Iron.
  - Platforms
    - Ground
      - Wood.
      - Stone.
    - Traversing
      - Wood.
      - Iron.
  - Ammunition
    - Powder
    - Shot and shells.
    - Case or cannister, spherical case, grape.
  - Stores in general.
- Instruction
  - Academical for Officers
    - Theoretical
      - Mathematics.
      - Fortification.
      - History and Geography.
      - Plan Drawing.
      - Landscape Drawing.
      - Languages.
    - Practical
      - Drills—both Infantry and Artillery.
      - Sword Exercise.
      - Gun and Mortar practice.
      - Repository Course.
      - Laboratory Course.
      - Foundry, Proof, and Carriage Department Courses.
  - Elementary Tactics for Non-Commissioned Officers and Gunners.
    - Theoretical
      - A Course of Elementary Instruction in the Schools.
    - Practical
      - Infantry Drill, and other exercise of Arms.
      - Field Battery Exercise.
      - Gun, Mortar, Howitzer, and Rocket practice.
      - Repository Course.
      - Partially Laboratory Course.

FIELD ARTILLERY.

When an army is to take the field, several considerations must be attended to in apportioning the number and calibre of the batteries to accompany it; as, the face, features, and general nature, mountainous or otherwise, of the country which is to form the theatre of war,—the state of its roads, and the resources which it can supply for the means of transport,—the force and description of troops composing the army,—the nature of the war, whether offensive or defensive,—and, lastly, the intended plan of operations.[2]

In carrying on offensive operations in a champaign country, with good roads and facility of transport, the artillery should consist of 9-pound batteries, to which 12-pounders, and probably a few 18 or light 24 pounders should be added, to form on occasion batteries of position. There should likewise be one or more batteries of a lighter calibre, to accompany any corps of the army that may be destined by rapid marches to intercept the enemy's convoys or detachments.[3] In mountainous or deep hilly countries, the artillery should not be composed of heavier ordnance than the 6-pounder battery; but an exact topographical acquaintance with the nature of the country is absolutely necessary, and indeed affords the only satisfactory guide for judging of the most appropriate calibres to be employed. When an army is to

[1] *Aide Memoire to the Military Sciences.*

[2] *Traité Elémentaire d'Artillerie.*

[3] D'Antoni.

Field Artillery.

remain on the defensive in a country where the roads are only tolerable, and the probability of being obliged to undertake long and rapid marches is not great, the artillery should be composed of a heavier description of batteries than would be proper to accompany an army acting offensively in the same country. But if this defensive system be carried on in a strong country, where the means of transport are attended with difficulty, and long and rapid marches may become indispensably necessary, the batteries must be so constituted as to adapt them to these several circumstances, otherwise the artillery will retard the army in its operations, instead of contributing to the attainment of the object in view.[1]

From considerations connected solely with the combined action of artillery and infantry, it has been deduced as a rule that a battery should consist of some multiple number of 2 guns, for example of 4, 6, or 8, and that howitzers should be combined with them also in pairs, making therefore a compound battery consist either of 4 guns and 2 howitzers as in France, or 6 guns and 2 howitzers as in Russia and most other European nations. The French battery has the great advantage of easy subdivision, as a half-battery would consist of 2 guns and 1 howitzer, and be therefore still complete in both natures of ordnance when called upon to act with the smallest independent force; and, at the same time, be in about due proportion to it. From the following historical examples of the relative proportions of artillery acting with various armies in different countries during the late war, it will be seen that experience has led to about the same proportions; and an officer, therefore, may, with the assistance of good topographical maps, form a tolerably accurate judgment on this important branch of military study.

The Austrian army, under the command of the archduke Charles in the campaign of Aspergne, Essling, and Wagram, consisted of about 75,000 men, to whom were attached 18 batteries of brigade, 13 of position, and 11 of horse-artillery; being nearly in the proportion of one piece of ordnance to 260 men.

The allied British and Portuguese army in the field in Spain, May 1813, consisted of 65,000 men and 102 pieces of artillery, including the reserve; being nearly in the proportion of one piece of ordnance to 622 men.

The grand French army under Napoleon for the invasion of Russia, not including the Austrian contingent, consisted of 400,000 infantry, 60,000 cavalry, and 1200 pieces of artillery; being one piece of ordnance to 383 men.

The French armies united on the Tormes in December 1812 amounted to 80,000 men and 200 pieces of artillery, being in the proportion of one gun to 400 men.

Napoleon in 1813 had 1400 pieces of artillery to 300,000 men, or one gun to 200 nearly. In 1815 his army consisted, as nearly as can be ascertained, by a comparison of several accounts of the campaign, of 130,000 infantry, 20,000 cavalry, and 300 pieces of artillery; being one piece of ordnance to 500 men.

The Prussian contingent of the grand French army for the invasion of Russia, under the command of General D'York, consisted of 20,000 men and 60 pieces of artillery; being nearly in the proportion of one piece of ordnance to 333 men.

Marshal Beresford, at the battle of Albuera, had 29,000 men and 32 pieces of artillery, or one gun to 900 men. His opponent Marshal Soult, in the same action, had 23,000 men and 40 pieces of artillery, or one gun to 575 men.

General L'Espinasse, who commanded the artillery of Buonaparte in Italy, supposes a division of an army to consist of 12,000 men, including a regiment of dragoons and another of hussars, to which he allots three batteries of horse and three of field artillery, each consisting of six pieces of ordnance. A battery of horse and another of field artillery are at all times to be up with the army; two batteries, similarly armed with the two in activity, are to remain with the park; and the remaining two, also appointed in like manner, should be in depôt in rear of the army. These proportions of artillery to infantry, L'Espinasse states, are precisely those adopted with the approbation of Buonaparte in the Italian campaigns.[2]

Positions and Movements of Field Artillery.

It has been pointed out that the principles on which the application of artillery should be regulated in the field, are the same as those which guide the engineer in the formation of his lines of intrenchments, his forts, or his fortresses. In fact the offensive action of artillery must be the same in its direction and objects, whether the guns are firing over a parapet, through an embrasure, or in the open field. The necessary exposure in the latter case may indeed render it expedient to rest satisfied with only a portion of the possible effect of the guns, so far as position is concerned, in order to gain for them greater security; but this does not invalidate the general principle.

The commanding officer of artillery, then, in order that he may choose proper positions for his field batteries, should be made acquainted with the effect intended to be produced, with the troops that are to be supported, and with the points to be attacked, that he may place his artillery so as to support, but not incommode the infantry, nor take up such situations with his guns as would be more advantageously occupied by the line; that he may not place his batteries too soon, nor in exposed situations; that he may cover his fronts and flanks by taking advantage of the ground; and that he may not venture too far out of the protection of the army, unless some very decided effect is to be obtained by so doing.

In a defensive position the guns of the largest calibre should be posted on those points from which the enemy can be discovered at the greatest distance, and from which the whole extent of his front may be seen. In an offensive position, the weakest points of the line, and those most distant from the enemy, must be strengthened by the largest calibres. Those heights on which the army, in advancing, may rest its flanks, must be occupied by guns, as also those from which the enemy may be fired upon obliquely.

Artillery should never be placed in such a situation that it can be taken by any enemy's battery obliquely, in flank, or in reverse, unless a position under these circumstances offers every prospect of producing a most decisive effect before the guns can be destroyed, or placed *hors de combat*. The most elevated positions are not the best for artillery; the greatest effects may be produced from a height of from 30 to 40 yards at the distance of 600, and from about 16 yards high at 200 yards distant. Those positions which are not likely to be shifted, but from whence an effect may be produced during the whole of an action, are to be preferred, and in such positions breastworks of two or three feet high should be thrown up to cover the carriages.

The guns must be so placed as to produce a cross-fire upon the enemy's position, and upon the ground over which he must pass to the attack. It may sometimes be necessary, in order to concentrate a cross-fire on one particular point, to subdivide the batteries, so that whilst the enemy's fire may be attracted to different objects, that of the opposing force is directed to a focus, such as the *débouché* of the enemy, the head of his advancing columns, or the ground in front of the weakest point in his own line. If the enemy's position is to be attacked, the fire of the attacking force must become direct in proportion as the troops advance, otherwise

[1] *British Gunner.*

[2] *Essai sur l'Artillerie*, par le Général L'Espinasse.

Field Artillery.

it will impede them; and when the fire can no longer be directed with safety on the point to be attacked, the guns must be directed on the collateral points.

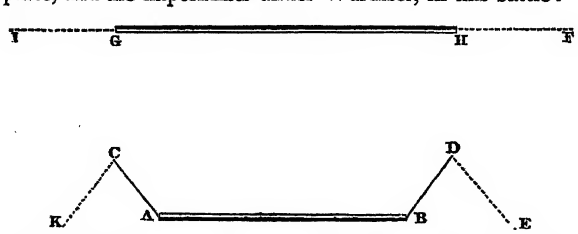
The guns should be placed as much as possible under cover. This is easily done upon heights, by keeping them so far back as that only the muzzles may be perceived over them. With proper attention, many situations may be found of which advantage may be taken for this purpose, such as banks, ditches, &c., everywhere to be met with. If an enemy's attack is expected, the guns must be posted so as to cannonade him with effect when he advances within 800 paces, and particularly in situations in which his march may be retarded by ditches, defiles, or other natural obstacles.

The position from whence the enemy is to be cannonaded should be kept concealed from him till the moment the batteries are to open. To effect this, the guns may until that time be placed in any other situation. Should there be any small elevations of earth in front of a defile through which the enemy may advance and be cannonaded, the guns must be kept under cover of them until he comes out and begins to form. The guns may also be masked by being covered by troops, particularly cavalry, until the enemy is within the range of case-shot. The covering party must then open right and left, and a brisk fire be kept up.

Artillery should very rarely be placed in front of a line of infantry, or distributed by batteries in the intervals. When the line is of great extent, it may become necessary to place a strong battery in the centre. This should be composed of the guns of the heaviest calibre; and it should be posted in the interval between the right and left wings of the army, by which means a double object is not offered to the enemy's fire. In general, an army in order of battle may be considered as a front of fortification, the infantry forming the curtain, and the lateral batteries the bastions, under the fire of which the troops may manœuvre freely, and advance with confidence to attack the enemy.

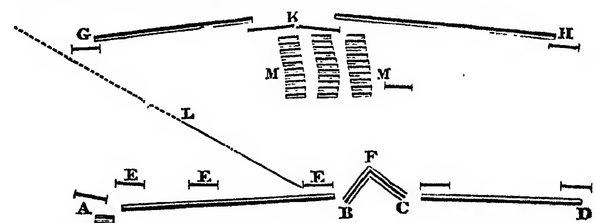
The two following examples will serve to illustrate the preceding remarks; and it may be observed in respect to the first, that had there not been heights in advance of the line of the French army which permitted the batteries to be arranged like flanks at the two ends of the line, the same effect might have been obtained by placing the guns *en echelon* along the space BE and AK of the following woodcut, and perpendicular to the lines BD and AC. This is indeed the system which the approved or official evolutions of artillery prescribe to be adopted.

Battle of Castiglione, 5th August 1796.—The following diagram shows the disposition of the French under Buonaparte, and the imperialists under Wurmser, in this battle:



A B the French army, G H the imperial army, A C a battery of 12 pieces of foot artillery, sustaining the left of the French on the heights in advance of Castiglione; B D a battery of 20 pieces of light artillery appuying on the right, which extended into the plain. The line of infantry A B being taken for the curtain, the batteries A C and B D may be considered as representing the faces of two bastions, thus forming a complete front, and crossing their fire before the curtain. The troops are consequently covered from attack, and the enemy fired upon obliquely. Wurmser having prolonged his front from G to I with the intention of outflanking the French, General L'Espinasse took some of the guns from C A, and placed them on the other face C K, until others could be drawn from the park for that purpose, thus forming a new battery destined to follow the enemy's movements. Another battery was likewise formed on the right, from D to E, in case Wurmser had prolonged his left from H to F.

Battle of Talavera, 27th and 28th July 1809.—At the commencement of the battle the British artillery were stationed, by batteries of 6 guns each, with the divisions of the army to which they were respectively attached; a temporary redoubt, unfinished, was thrown up at F, in which a battery of 3-pounders was posted; on the hill at A, the most commanding point of the position, two batteries were posted, one of heavy 6-pounders, the other of light sixes, to which two Spanish guns were afterwards added.



The French had a battery of 14 guns at K, the centre of their position; also one at each of the flanks G and H, independently of others which were brought up during the action. On the second day, when the columns at M advanced, supported by artillery, to attack the British right, which rested on the unfinished redoubt, the three batteries, E E E were formed on the oblique line L E, and thus took the advancing columns in flank, whilst the redoubt kept up a direct fire in their front.

It must here be observed, that whenever an oblique line is formed by artillery, as from L to E, it must be directed without the extremity of the enemy's flank, otherwise the guns will be exposed to his enfilading fire.

On considering the more general application of artillery, it is desirable to attend to the peculiarities in the mode of action of the several natures of ordnance, as exhibited in the following classified arrangement:—

ARTILLERY	Force produced by a sudden development of gaseous bodies in a state of high tension, by the almost momentary ignition of gunpowder.	The progressive velocity of the missiles, shot, musket-balls, fragments of shells, either entirely or mainly depending on the velocity derived from the projectile.	Guns, Carronades, Howitzers.
		Velocity of the fragments of the bursting shell, depending principally on the bursting powder of the shell itself.	Mortars.
	Force produced by a gradual development of gaseous bodies in a state of tension, by the progressive ignition of gunpowder.	... ...	Rockets.

An examination of this table shows that guns and howitzers should be used wherever it is desirable or necessary that the missile should possess a progressive movement, or a penetrating power in a progressive direction, as in firing at parapets, or in enfilading a long line of parapet; but that mortars should be used wherever it is required to act in a vertical direction, either for the destruction of a work which cannot be got at by a direct fire, or to assist the enfilade fire, when it is found, from the number of traverses, or the position of the ground on which the work stands, that the fire of the guns and howitzers has not been effectual. Keeping these points in view, we proceed to the next subject.

SIEGE ARTILLERY.

The first duty of the commanding officer of artillery, when it is intended to besiege a fortress, is to prepare an estimate of the quantity of ordnance and ammunition required for its reduction. To enable him to make this estimate with accuracy and precision, he should be master of certain data; that is to say, the commander of the forces, or general charged with the direction of the siege, should communicate to him a plan of the fortifications and environs of the place, accompanied by such profiles and remarks as may enable him, in conjunction with the commanding engineer, to ascertain which front or fronts are most assailable, with the advantages and disadvantages attending each attack, as well with respect to the works of the place as to the nature of the soil where the trenches must be opened, and the several heights and hollows of the vicinity.[1] He should also, if possible, be informed as to whether the place be amply supplied with artillery, ammunition, &c.; if the garrison be sufficiently numerous, and whether composed of veteran troops or raw levies; if the governor be in high estimation for his military talents; if the town be populous, and the inhabitants well affected to the garrison.[2] It will thus be easy to form a tolerably accurate opinion of the means of defence, and the resistance to be expected; for it is not to be presumed that any government would shut up a brave and numerous force in an ill-fortified and badly-provisioned place, at the risk of seeing such a garrison sacrificed after a short resistance.

But should it be impossible to procure information on these several points beforehand, particularly as to the strength of the garrison, the requisite proportion of ordnance and ammunition must be regulated on the general principles of attack. The officer intrusted to prepare the estimate must, therefore, endeavour to ascertain, according to the fundamental maxim of all besiegers, against which front or fronts the attack can be made with the least exposure and greatest expedition. He should examine whether the siege can be most advantageously carried on by regular approaches; by taking advantage of any defect in the situation which may enable him to break ground close to the works to be breached; or by battering them from a distance. By the aid of this investigation and the following general principles, the quantity of ordnance and ammunition required for the siege of a place may be ascertained with reasonable accuracy.

General Principles for the Attack of Fortified Places.

1. The number of batteries to be opened against the defences must depend upon the extent of the works to be embraced by the attack, *i.e.*, there must be a battery to enfilade every face that can in any way annoy or retard the besiegers in their approaches; but should this render it necessary to extend the parallels to an inconvenient distance from the actual direction of attack, the fire of the extreme faces of the enemy's works may be silenced by direct batteries.

2. The length of the epaulement of these batteries need not exceed the breadth of the terreplein of the works to be enfiladed, unless circumstances should render it necessary to place some of the guns in a situation to take the work in reverse. Each battery will only contain, therefore, five, or at most eight guns, to enfilade the face of the principal work; to which must be added two others to enfilade the branches of the opposite covered way.

3. The situation of the breaching batteries must be carefully determined, as, in a regular attack, they might sometimes interfere with the fire of the first or enfilading batteries. Should this be the case, the same artillery may be transferred from one battery to the other. It must be remembered, that though in the actual breaching batteries the guns should fire as nearly as possible perpendicular to the revetment to be battered down, it is by no means absolutely necessary to fire so nearly perpendicular when the object, as in the earlier direct batteries, is merely to ruin the earthen parapets. In this latter case, convenience may be attended to without scruple, and even some danger occasionally avoided by adopting a more oblique fire.

4. The supply of ordnance must be sufficiently liberal to enable the besiegers to keep up a fire constantly superior to that of the place. This supply therefore must be determined by the construction and extent of the fortifications of the place; taking care that, in addition to the guns required for enfilading batteries, there should be a preponderating number to act against every portion of the fortress possessed of the power of firing directly and effectively against the besiegers. The number of siege guns will therefore have a natural relation to the number adopted for defence.

5. As the *ricochet* firing may be interrupted while the sappers are completing the third parallel, a supply of royal and cœhorn mortars must be provided to harass the garrison from the second parallel, or demi-places of arms, during its cessation.[3]

Having thus ascertained the number of guns required, the following will be their calibres, and the proportions which the remaining ordnance should bear to them.

Guns—of the whole number required—suppose 60.

24-pounders.................................... $\frac{2}{3}$ or 40
12-pounders.................................... $\frac{1}{3}$ or 20

Howitzers—one for every four guns—in this case 15.

10-inch.. $\frac{1}{3}$ or 5
8-inch.. $\frac{2}{3}$ or 10

Mortars—in the proportion of one-twelfth more than the number of guns—in this case 65.

10-inch.. $\frac{2}{13}$ or 10
8-inch.. $\frac{3}{13}$ or 15
Royal.. $\frac{4}{13}$ or 20
Cœhorn .... $\frac{4}{14}$ or 20

In the above proportion of ordnance, it must be observed that the long 12-pounder is proposed instead of the 18-pounder formerly employed, as a gun of this description is conceived to be sufficiently powerful for annoyance and direct fire, to dismount the ememy's artillery, as well as for firing *en ricochet*. The diminished weight of ammunition attendant on the employment of the smaller calibre is an important advantage; but it is an arrangement which can only be admitted in cases where an adequate number of 24-pounders are provided. In all smaller equipments it would, therefore, be better that all the guns should be of the heavy calibre.[4]

The proportion of small mortars should in no case be less than that of the heavy mortars and howitzers, and this proportion ought to be increased in all equipments of less than thirty pieces of ordnance. Indeed, when sent at all, there should be at least twelve of them, to insure the necessary effect. In many cases a far greater number than is here

[1] *Traité Elémentaire d'Artillerie.* [2] *British Gunner.* [3] *Ibid.* [4] *Ibid.*

proposed could be advantageously used; but this must of course depend on the nature of the service on which they are likely to be employed. The royal and cœhorn mortars have, in the present instance, been taken in equal proportions, and it would be advisable to adhere to this arrangement in all the larger equipments, particularly when their calibres correspond with those of the guns; but in small equipments it would be more convenient to confine the arrangement to one calibre, in which case the royal mortar is the preferable, as it possesses the power of being used at a greater distance than the cœhorn. But it must at the same time be observed, that the latter, from its lightness and the small weight of its ammunition, is a more desirable implement for the more advanced parts of the attack.

The proportions per cent. of the ordnance here recommended, stand as follow:—

24-pounders	28·6	42·9	
12-pounders	14·3		
10-inch howitzers	3·6	10·7	
8-inch do.	7·1		
10-inch mortars	7·1	17·8	46·4
8-inch do.	10·7		
Royal	14·3	28·6	
Cœhorn	14·3		
	100·0		

A park of siege artillery in France consists of—

50 to 58 guns, either 24 or 16 pounders.
12 to 14 howitzers, of 8 inches.
10 to 14 mortars of heavy calibre.
6 to 8 do. of light calibre.

78 to 94 pieces:

Being, per cent.—

Guns—heavy	64·1	
Howitzers	15·4	
Mortars—heavy	12·8	20·5
Do. light	7·7	
	100·0	

giving a much larger proportion of guns and howitzers than that proposed by Captain Spearman.

In Austria the park is composed, per cent., of

Guns—24 and 16 pounders	40	47
Do. 12 pounders	7	
Howitzers	13	
Mortars—heavy	11	33
Do. light	22	
Do. stone	7	
	100	

proportions somewhat nearer to Captain Spearman's.

In Prussia the park is composed of—

Guns—24 and 18 pounders	48	58
Do. lighter calibre	10	
Howitzers	16	
Mortars—heavy	10	20
Do. light	10	
Do. stone	6	
	100	

proportions approaching more nearly to that of the French army. On the whole, it may be assumed that a satisfactory proportion might be deduced from all these, giving more guns than in Captain Spearman's, and more mortars than in the French arrangement, viz.:—

Guns	50	
Howitzers	15	
Mortars—heavy	15	35
Do. light	20	
	100	

The quantity and relative calibres of the ordnance being determined, the following will be the proportion and nature of ammunition:—

Gun ammunition.—Round shot,
24-pounder .... 1000 rounds per gun.
12-pounder .... 1200 rounds per gun.
Tier shot .... 50 rounds per gun.
Spherical case .... 100 rounds per gun.
Howitzer ammunition.—Shells,
10-inch .... 600 rounds per howitzer.
8-inch .... 300 rounds per howitzer.
Spherical case,
8-inch .... 300 rounds per howitzer.
Carcasses .... 10 rounds per howitzer.
Valenciennes composition,
10-inch ...... 100 proportions per howitzer.
Mortar ammunition.—Shells,
10-inch .... 600 per mortar.
8-inch .... 600 per mortar.
Pound shot,
10-inch... 50 rounds of 100 shot each per mortar.
Carcasses,
10-inch .... 10 per mortar.
8-inch .... 10 per mortar.
Valenciennes composition,
10-inch........ 100 proportions per mortar.

In the above proportion of ammunition there is an increase of 200 rounds in favour of the 12-pounders, as the facility of working these guns will, at an easy rate, afford the means of firing more rapidly than from 24-pounders. The proportion of one-half common shells and one-half spherical case should always be adhered to for the 8-inch howitzers.

Arrangement of Artillery at a Siege.

The first disposition of the artillery at a siege is to the different batteries raised near the first parallel. The object of the besieger in the construction of these batteries is, by a direct and enfilade fire, to dismount the artillery on the front attacked, destroy the embrasures, and harass the garrison in the several points of defence, so that they may be compelled to abandon them, or at least slacken their fire, and thereby enable the besieger to carry forward his approaches with greater expedition and less danger than he otherwise could do.[1] If these first batteries be favourably situated, the artillery may be continued in them during the whole of the siege, or until the besiegers arrive on the crest of the glacis. The garrison must be perpetually harassed along the whole front attacked, with shot and shells fired *en ricochet*. The batteries for this purpose are erected on the prolongations of the works to be enfiladed, from whence the defenders of the prolonged faces may be fired upon with great precision and effect.[2] It, however, frequently happens, from local and other circumstances, that the besiegers cannot avail themselves of the most advantagous situations for their first batteries. There are four situations from which the defences of a place may be destroyed, though not from all of them with equal facility. The best positions for the first batteries are those before described as perpendicular to the prolongations of the faces of the works to be enfiladed. If these positions cannot be attained, the next that present themselves are on those sides of the prolongations which take the faces in reverse, and under as small angles as possible. If the ground or other circumstances will not admit of either of these situations being occupied by enfilading batteries, the battery to destroy the fire of the face must be without its prolongation, so as to fire obliquely upon the outside of it: the fourth position in point of advantage is directly parallel to the face, or within that degree of obliquity which will allow a sufficient penetrative force to the shot or

[1] *Essai Générale de Fortification.*

[2] *British Gunner.*

Garrison Artillery.

shells. The guns must fire *en ricochet* from the first two positions, and from the last two with full charges.

The second batteries are generally placed on the glacis, within 15 or 18 feet of its crest; but if the foot of the revetment cannot be seen from this situation, they must be placed in the covered way, within 15 feet of the counterscarp.[1] The object of these second batteries being to effect practicable breaches in the works, they should be combined, two and two together, so that while one batters in breach, the other may play upon its defences. The breaching batteries shall commence by marking out as nearly as possible, by their fire, the extent of the breach intended to be made; first by striking out a horizontal line as near as possible to the bottom of the revetment; and next, by aiming at two others, perpendicular to and at the extremities of this first line. Then, by continuing to deepen these three cuts, and occasionally firing salvoes at the part to be brought down, the wall will in time give way in a mass. The guns must begin by firing as low as possible in the commencement of the operation, afterwards somewhat higher in the same manner as before, and so continue advancing gradually upwards till the breach is effected; for, should they fire too high at first, the rubbish would cover the lower part of the wall, retard the operation, and tend to render the breach impracticable. When the second batteries are placed on the glacis, or in the covered way, they must be sunk to such a depth that the terreplein of the one, or surface of the other, may coincide with the soles of their embrasures. They are in fact but an enlargement of the sap run for the lodgment on the glacis, or in the covered way, and should contain at least four guns each. If the space between the traverses will not admit of this number at the usual distances, the guns must be closed to distances of fifteen or twelve feet from each other.

The mortars are generally arranged at first in battery adjoining the first gun batteries, or upon the prolongations of the capitals of the works, in which situations they are certainly least exposed; and upon the establishment of the half parallels the howitzers are placed in battery, in their extremities, to enfilade the branches of the covered way. These batteries are in the most advantageous situations, if, while the one bombards the work that the besieger intends to assault and prevents the garrison from throwing up intrenchments within it, or at least retards their construction, the other directs its fire against the defences of the breach, so that the garrison may, from the continual shower of shells, &c., be compelled to abandon them, or, if they persist in remaining, be exposed to great loss. The small mortars are arranged in the third parallel, to annoy the besieged in the places of arms.

Mortars may also, as stated before, be advantageously placed opposite the prolongation of a face, on the same principle as an enfilading gun battery; and in this case they may be arranged one behind the other, being separated by traverses or epaulements.

In the establishment of all these batteries, the great object is to make such an arrangement of them, that they may not mask the fire of each other more than is unavoidable, and particularly that of the first or *ricochet* batteries. The aggravation of this inconvenience may very well be prevented till the establishment of the attack on the crest of the glacis, when it becomes in some degree unavoidable: however, even the operations of the glacis may be so arranged as not to mask the fire of the *ricochet* batteries, until the breaching batteries are in a state of great forwardness.

GARRISON ARTILLERY.

The proportion of ordnance, ammunition, and stores required for the defence of a fortified place depends not only on the particular situation of each individual fortress, and its relations with the surrounding country; the system according to which it is fortified, and the species of attack it may be possible to open against it; but likewise on innumerable minor circumstances, each of which may exert an important influence on the defence. If, for example, one or more of the fronts of a place be covered by an inundation, a marsh, or by any other impassable obstacle, it will manifestly require a much smaller proportion of artillery for its defence than if it were equally accessible on every front. On the contrary, a maritime fortress, which is susceptible of attack both by sea and land, will require a larger proportion of ordnance supplies than if it were assailable from only one of these points.[2]

It will be seen, therefore, from the above remarks and examples, how impossible it is to lay down any general rules upon this important subject. The only satisfactory guide which an officer charged with the nice and responsible trust of arming a fortified place can with security follow, is to examine attentively all parts of the works and of the surrounding country, and then to weigh every other circumstance that can in any way influence the defence. He should consider which of its fronts are most vulnerable, and what measures are best adapted for their security. To effect this with accuracy and expedition, he should, after a few days passed in reconnoitring and studying his position, devote his attention to the preparation of a sketch and profiles of the works and neighbouring country, as far at least as a mile in every direction, and upon a scale adapted to the features of the ground.

With this map and profiles before him, he should recur to those fundamental principles upon which every good attack and defence are based. He should not only be thoroughly acquainted with his own particular branch of the service in all its details, but capable of judging to the fullest extent of all operations in which the other troops of the garrison can bear their part; so that every supply may be adequate to its particular purpose, without deficiency on the one hand or superfluity on the other. Thus two extremes, equally prejudicial, will be avoided; the one, of making a provision insufficient for the defence which the fortress is capable of sustaining; the other, of providing such a quantity of supplies, that, on its capitulation, which, according to the natural order of things, must sooner or later happen, if it be not relieved, a complete arsenal would fall into the enemy's hands.[3]

These observations being held in mind, the following general maxims will be found of essential assistance.

General Maxims for arming Fortified Places.

1. The proportion of ordnance, ammunition, and stores should never exceed the quantity absolutely necessary to a brave and resolute defence.

2. Those fronts which are considered susceptible of attack should be completely armed, and the remaining fronts armed only in part.

3. There should be, for each of the faces of the bastions of such fronts as are deemed liable to attack, five or six pieces of ordnance; for each of the flanks of these bastions four pieces; and for the faces of the ravelin from five to seven pieces of ordnance. When there are lunettes, four pieces should be reckoned for each, and from two to three for each of the places of arms of the covered way. Supposing, therefore, one front to be completely armed, the following proportion of ordnance will be required

The faces of the two bastions	from 10 to 12
two interior flanks	from 6 to 8
faces of the ravelin	from 5 to 7
five places of arms	from 10 to 15

[1] *Traite d'Artillerie*, par D'Antoni; *British Gunner*.

[2] *British Gunner*.

[3] *Traité Elémentaire d'Artillerie.*

Garrison Artillery.

making a total for one front of from 33 to 42 pieces of ordnance.

4. In case of the place being liable to attack on two consecutive fronts, the above proportion should be augmented one half; and if on two detached fronts, it should be doubled. The remaining fronts should each be provided with such a proportion of their full armaments as will secure them from insult. It will appear from the above maxims, which are deduced from the best authorities on the subject, that a hexagon, having only one front exposed to attack, requires an armament of from 58 to 68 pieces of ordnance for its defence; and that for more extensive places, from six to eight, or at most ten pieces of ordnance, should be added for each additional front.[1]

The next point to be considered is the proportion which the several kinds of ordnance, and their relative calibres, should bear to each other; and here it must be remembered that the higher rates are not the only descriptions capable of being employed to advantage in the defence of a place. There are many cases in which medium guns can oppose equal resistance with the heavier calibres, and they possess the very important advantage of affording greater facility in manœuvring and transporting them from one situation to another; an operation of considerable difficulty with the higher natures of ordnance at all times, but particularly during a siege. They also consume less ammunition, and enable the besieged to keep up a more determined and incessant fire.[2]

The following are the proportions of the several kinds and calibres usually adhered to in ordinary cases.

Guns—in the proportion of two-thirds of the whole armament—suppose 60.

24-pounders	$\frac{1}{10}$ or 6
18-pounders	$\frac{2}{10}$ or 12
12-pounders	$\frac{3}{10}$ or 18
9-pounders or 6-pounders	$\frac{4}{10}$ or 24

Howitzers—one for every five guns—in this case 14.

10-inch	$\frac{1}{2}$ or 7
8-inch	$\frac{1}{2}$ or 7

Mortars—in about the same proportion as the howitzers—in this case 16.

10-inch	$\frac{1}{2}$ or 8
8-inch	$\frac{1}{2}$ or 8

The above distribution of guns, howitzers, and mortars, applies equally to all armaments of not less than 60 pieces of ordnance; and such an armament should therefore consist of 40 guns, 8 howitzers, and 12 mortars. The proportions of the several calibres of each kind, except those for the guns, are calculated on a basis of not less than 90 pieces of ordnance; and in all smaller armaments it would be advisable to confine the arrangement to two calibres of each kind only.

The preceding estimate of 68 pieces of ordnance for a hexagon must be taken as the least possible number, as it implies a very partial arming of the fronts not included in the scheme of attack, and a defence limited to a single front. To bring this up to a sufficient standard on the principles of estimate adopted, the following calculation may be given.

Faces of the centre bastion of the attack	12
Nearest faces of collateral bastions	12
Two flanks opposed to centre bastion	8
Two flanks of centre bastion	4
Adjacent faces of two adjacent ravelins	8
Remote faces of do.	4
Four adjacent places of arms	12
Two remote do.	8
	68
Armament of remote halves of two adjacent bastions	10
Armament of three other bastions at 10 pieces of ordnance for each bastion	30
	40

Colonel Timmermans gives 62 guns and howitzers, and 42 mortars, or 104 in all; besides some few stone mortars; and the Fortification Course of the Royal Military Academy 130, namely, 65 heavy guns, 13 howitzers, 39 mortars, and 13 field guns. If then the same proportion be adopted on the total number of 110 for a hexagon, the number of heavy guns will be 55, of howitzers 11, of mortars 33, and of field guns 11, which appears a very reasonable estimate for ordinary circumstances. In carrying it into effect, the number of field guns should, of course, be adopted which corresponds to the ordinary arrangements of field batteries; as, for example, 12; being two batteries of the present establishment, or $1\frac{1}{2}$ of that proposed.

In respect to the calibre of guns used in the defence of fortresses, the remarks of Colonel Timmermans deserve especial attention. He observes,

1*st*, That the superiority of attack over defence is in great measure due to the improvement of the siege artillery and operations, without a corresponding improvement in the defence, and hence that an improvement in the artillery of a fortress should tend to restore the equilibrium.

2*d*, That as the besieger is limited by the difficulty of transport to the use of guns of moderate calibre, the besieged should adopt guns of a more powerful calibre, so as to commence an effective contest with the besieger even at the earliest stage of the siege.

These remarks are just, and it would seem assuredly desirable to establish a superiority of calibre in the guns of defence whenever it is possible so to do. The present established table of ordnance exhibits the 8-inch shell gun 8 feet long, and weight 52 cwt; the 32-pounder 9 feet 6 inches long, and weight 56 cwt.; and the short 32-pounder 6 feet long, and weight 25 cwt.; which seem peculiarly fitted for the armament of fortresses, and are not so greatly different even in weight from the 24-pounder, which weighs 50 cwt., as to render their use difficult. Mortars also should be freely used in the collateral bastions, their fire being directed not against the battery nearly opposite to them, but against the battery opposite the corresponding bastion on the other side, so as to fall as nearly as possible in the direction of the parapet. Spherical case should also be freely used as a most effective missile. It may be added also as an argument in favour of heavy ordnance, that when the fortress has fallen, the guns will not be suitable for transport in the field.

The following will be the proportion and nature of ammunition for each species of ordnance.

Gun ammunition.—Round shot,

24-pounder	600 rounds per gun.
18-pounder	760 rounds per gun.
12-pounder	800 rounds per gun.
9-pounder or 6-pounder	1000 rounds per gun.

Case shot,

24-pounder	40 rounds per gun.
18-pounder	50 rounds per gun.
12-pounder	80 rounds per gun.
9-pounder or 6-pounder	100 rounds per gun.

Spherical case,

24-pounder	50 rounds per gun.
18-pounder	80 rounds per gun.
12-pounder	100 rounds per gun.
9-pounder or 6-pounder	150 rounds per gun.

Howitzer ammunition.—Shells,

10-inch	400 rounds per howitzer.
8-inch	600 rounds per howitzer.

[1] *Manuel de l'Artilleur; Traité d'Artillerie*, par D'Antoni

[2] *British Gunner.*

Garrison Artillery.

Case shot,
10-inch .... 100 rounds per howitzer.
8-inch .... 250 rounds per howitzer.
Spherical case,
8-inch .... 500 rounds per howitzer.
Light balls and carcasses,
8-inch .... 20 rounds of each per howitzer.

Mortar ammunition.—Shells,
10-inch .... 500 rounds per mortar.
8-inch .... 650 rounds per mortar.
Pound shot,
10-inch .... 500 rounds per mortar.
8-inch .... 600 rounds per mortar.
Each round of pound shot consists of 100 shot for the 10-inch, and of 80 for the 8-inch mortar.
Light balls .... 15 per mortar.

The above proportion of ordnance and ammunition for the defence of a fortified place is exclusive of one or more field batteries, which every place should contain, according to its extent, and which should be provided with a double proportion of ammunition: and it is only necessary to alter the calibre from 24 to 32, to reconcile it to the views previously expressed of the advantage of heavier ordnance.

This estimate and arrangement is founded upon the supposition that the place is unprovided with casemated batteries, the armament for which must of course form a separate estimate, calculated, however, upon the same principles as the above.

Arrangement of the Artillery during a Siege.

The instant it is ascertained that the enemy's troops are in motion towards the place,—presuming that it is amply supplied with provisions, ammunition, and stores, and that every precaution has been taken to collect from the vicinity what might fall into the enemy's hands,—the barbette batteries must be established in the flanked angles of the bastions and ravelins, and a proportion of the light guns and howitzers must be placed in the outworks and covered way. Should the body of the place have cavaliers, the heaviest guns should be mounted on them. The following arrangement is usually made for the reception of the investing corps, when it is not known from what point they may advance to commence operations.

There should be three guns mounted on the barbette of each bastion—one 24 and two 18-pounders, and three 9-pounders on the barbette of each of the ravelins. In the salient places of arms of the bastions, one 24-pounder howitzer, and in those of the ravelins two 6-pounders. The heavy mortars should be placed one in each bastion, and the remainder of the ordnance in reserve behind the curtains, ready to move on whichever side it may be required. As it is always very desirable to have as few calibres as possible, the 9-pounders might be advantageously replaced in all cases either by 12-pounders or by 6-pounders, according to the special circumstances; and the armament consist in general of the 8-inch shell gun, long 32, short 32, 12 feet and 6 feet, besides the field batteries.

By this arrangement the whole of the barbette guns, and of the guns and howitzers in the outworks and covered way, will be in readiness to act in any direction, till it is known on which side the enemy has determined to direct his attack, and, with the addition of the reserve, will enable the besieged to open a fire of thirty-five pieces of ordnance on the enemy, the very first night he begins to work upon the trenches. In the first moments of the investment, however, the artillery of the place should not endeavour, by a useless expenditure of ammunition, to disturb the besiegers in their operations; it is only when they are making permanent dispositions for their establishment that the fire of the place should be opened upon them. It is nevertheless necessary that some guns should be loaded with reduced charges to protect the retreat of the advanced posts, and mislead the enemy as to their range. This is also the moment, if the garrison be numerous, and composed of good troops, to annoy the besiegers by sorties on different points of the line of contravallation, and to retard the works necessary for establishing their communications; care must however be taken not to purchase this advantage by a loss of men and artillery, which would cripple the means of defence.

Coast Defences.

The day succeeding the night on which the trenches are opened, and the front of attack determined, a new disposition of the artillery of the place must be made as follows:—

The 24 and 18-pounders must be removed to the front attacked, and the other batteries, if necessary, supplied with 12-pounders. The barbettes of the bastions on this front must have each five guns, three 24 and two 18-pounders, and the remaining 18-pounders arranged behind the curtains,—two towards each of the extremities of the front curtain, and two at the farthest extremity of each of the collateral curtains. The howitzers in reserve should be placed two in each of the salient angles of the covered way of the bastions of this front, and two in each of those of the collateral bastions, which, with those already there, must fire *en ricochet* down the prolongations of the capitals. There should also be three 6-pounders in the salient place of arms of the ravelin of the front attacked, and three in each of those of the two collateral ravelins; these guns should fire over the palisading; and, lastly, there should be five 9-pounders on the barbette of the front ravelin. This arrangement will bring fifty-two guns and howitzers and four mortars to fire on the approaches after the first night. This, with a few variations, will be the disposition of the artillery of the place till the besiegers' first batteries are ready to open. The instant they begin to work upon these batteries, the whole fire of the place must be concentrated on them, and the mortars which had previously fired at low angles must now fire with greater elevation, but at all times sparingly.

As soon as the enemy's batteries are fairly established, the guns *en barbette* must be covered by merlons, and the embrasures occasionally masked. While this work is carrying on, the situations of the guns should be changed, and new directions given to them; as by frequently practising this manœuvre, the enemy will also be obliged to change his dispositions of attack, and time will thereby be gained by the besieged. As the enemy approaches towards the second parallel, the fire of the place must be spread over all parts of his line of operations; and with a view of contributing to this object, royal and cœhorn mortars should be disposed in the places of arms and branches of the covered-way. When the approaches are carried on from the second parallel, and the enemy is about to establish the demi-places of arms, the fire of the place must be concentrated on the *débouchés* from the parallel, and multiplied with all possible activity.

In proportion as the besieger pushes forward his approaches to the third parallel, the artillery must be withdrawn from the covered way to the ravelins, or to the ditch, if dry, or to any other favourable situation, and by degrees, as they advance, to the body of the place. During this period of the siege the embrasures must be prepared in the flanks, in the curtain which joins them, and in those parts of the faces of the bastions which command the ditch of the front ravelin. All these embrasures must be ready to open, and the heavy artillery mounted in them, the moment the enemy attempts to form a lodgment on the glacis. We have now arrived at the crisis of the siege, and every effort should be made to take advantage of this favourable moment, when the enemy, by his own works, must mask his former batteries, and before he is able to open his new ones.

COAST DEFENCES.

In a preceding paragraph, the opinion of Colonel Tim-

mermans of the Belgian artillery has been quoted in favour of the use of ordnance of high calibre in the defence of fortresses, and that of Marshal Marmont might be quoted to the same effect. "I come now," he observes, "to the artillery of Paixhaus. To fulfil their object, heavy guns should have a great range, and their missiles a great momentum. Hitherto this momentum has been obtained by the use of a moderate mass projected with a great velocity, on account of the difficulty of moving heavy ordnance; but though this reason is unanswerable in a siege where the guns must be moved in a limited time, and often under circumstances of great difficulty, it does not apply to the armament of ships, of fortresses, or of coast defences; in all of which cases such heavy artillery must possess immense advantages." In respect to coast defences the force of this reasoning has been fully admitted, as the effect even of a 32-pounder shot is small in comparison with that of an 8-inch hollow shot which weighs 56 pounds, and makes a fearful rent in a ship's side, which it would be difficult to stop up or repair.

The armament, therefore, for coast batteries, forts, or towers, includes guns of the highest calibres, viz.:—

1. 68-pounder for sweeping channels of more than ordinary length, so as to bring the ship within range as soon as possible.

2. 10-inch shell gun, to defend a point of very great importance, where a more than usually heavy fire is required.

3. 8-inch shell gun and 32-pounder of 56 cwt. as the general armament in the proportion of one shell gun to two 32-pounders. Both these guns can be used for setting fire to shipping, the one by shells and the other by red-hot shot, and therefore fulfil most of the conditions required for coast-battery guns. Lighter guns of similar calibre may be used for very short ranges, but it should always be borne in mind that as the efficiency of defence, since the application of steam as a motive power in ships, rests on the destructive effects of a few shots, and not on the repeated shocks of many, guns of a large calibre ought to have almost an exclusive preference, both from the superior precision and superior destructiveness of their fire. The 24-pounder has still been retained on the Ordnance Lists for protecting shallow beaches; but even in this case the short 32-pounder would be preferable, and the introduction of another calibre might be avoided.

EXERCISE OF ARTILLERY.

The several exercises are divided into three classes, as follows:—

1. Exercise of field artillery.
2. Exercise of garrison or siege artillery.
3. Exercise of the various machines employed in the manœuvres of garrison or siege artillery.

1. *Exercise of Field Artillery.*

The complement of men for the service of each gun or howitzer is, one non-commissioned officer and eight gunners.

Numbering and Telling off the Detachments.

The several detachments being arranged right in front, are numbered and told off by their respective non-commissioned officers in the following manner:—

The non-commissioned officer is invariably No. 1, and is responsible for the proper execution of the duties of the other numbers of his detachment. The right-hand man of the rear rank is named No. 2; his front-rank man No. 3; the second man from the right of the rear rank No. 4; and his front-rank man No. 5; and so on in succession from the right of the rear to the left of the front rank, till the numbering of the whole detachment is completed.

Formation in Order of March or for Exercise.

When detachments are formed in the order of march, or for the purpose of exercise, the even numbers are almost invariably on the right or off-side of the gun, and the odd numbers on the left or near side.

Positions of the several Numbers in Action.

No. 1 is on the left of the handspike; No. 2 outside the right wheel, in line with the muzzle; No. 3 outside the left wheel, and also in line with the muzzle; No. 4 clear of the right wheel, covering No. 2, and in line with the breech; No. 5 clear of the left wheel, covering No. 3, and also in line with the breech; No. 6 five yards in rear of and covering the left wheel; No. 7 in rear of the limber; No. 8 ten yards in rear of the gun, in line with the heads of the leading horses of the limber; and No. 9 attends the ammunition-waggon.

Duties of the several Numbers.

No. 1 points and commands; No. 2 sponges; No. 3 loads; No. 4 serves the vent and primes; No. 5 fires; No. 6 serves No. 3 with ammunition; No. 7 supplies No. 6 with ammunition, and, when firing shells, fixes the fuses; No. 8 assists No. 7, and occasionally relieves No. 2, or, when attached to $5\frac{1}{2}$ inch or 24-pounder howitzers, provides No. 3 with shells; No. 9 assists in preparing ammunition.

Limbering up, or Retiring from Action.

This manœuvre may be performed, according to circumstances, to the front, rear, right, or left. In limbering up to the front, the limber drives up to the right of the gun. No. 2 instantly passes his sponge over the axletree to No. 4, who straps on the sponge head; No. 2 and No. 3 go round to the trail; No. 4 and No. 5 man the wheels, assisted by No. 7 and No. 8 with heavy guns. The right wheel is run back, the left forward, and No. 1 and No. 6 throw the trail round in the opposite direction to that in which the limber drives up. The instant the trail is round, No. 1 unships his handspike, and No. 5 straps it on; No. 2 buckles on the rammer-head of his sponge, and the whole fall in close to the wheels. No. 6, No. 4, and No. 2 on one side, No. 5, No. 3, and No. 1 on the other; No. 7 attends the limber, and No. 8 moves up to his place. On the limber coming up square to the front, No. 1 orders, "halt, limber up," upon which No. 4 and No. 5 man the wheels, No. 2, No. 3, and No. 6, lift the trail and place it on the pintail; No. 1 then puts in the key, and the detachment mount, or fall into the order of march. The duties are precisely the same in limbering up to the rear, right, or left, except that in limbering up to the right or left, the trail and limber both go to the right or left; and in limbering up to the rear, the limber drives up rather to the right of the trail, which is not thrown round, and then reverses to the left.

Unlimbering or coming into Action.

This is precisely the reverse of the preceding manœuvre. No. 1 unkeys the pintail, No. 2 and No. 3 raise the trail, and when it is clear No. 1 gives the word, "Drive on;" upon which the limber goes off to the left about, and the trail is thrown to the right about, the other numbers assisting as they arrive, the same as in limbering up, No. 6 at the trail with heavy guns, and No. 4 and No. 5 at the wheels. As soon as the trail is down, No. 5 unbuckles the handspike, and No. 1 ships it; No. 2 unstraps the rammer-head and goes to his place; No. 4 unstraps the sponge, and passes it over to No. 2. When the limber is sufficiently to the rear, it reverses to its left, and halts ten yards in rear of and covering its gun. The ammunition-waggon also reverses to its left, goes off in front of the limber, and again reversing, to its left, halts one horse's length in rear of the gun-limber. No. 1 is responsible for the correct dressing of his gun when it comes into action; and for this purpose, immediately after the trail is in its proper direction he should place himself in line with

Exercises. the axle-tree of the gun upon which the formation is made, and dress his own gun with it. This position will enable him to see, not only that his gun is in its true *alignement*, but also that it is square to the front.

2. *Exercise of Garrison or Siege Artillery.*

This second branch of the exercises relates to the manner of working and serving guns, howitzers, carronades, and mortars, on batteries. The complement of men for the service of garrison or battery guns is, for the 42-pounder and 32-pounder, one non-commissioned officer and six gunners each; for the 24-pounder, one non-commissioned officer and five gunners; for the 18-pounder, one non-commissioned officer and four gunners; and for the 12-pounder and 9-pounder, one non-commissioned officer and three gunners each. The complement of men, duties, &c., are precisely the same for howitzers and carronades as the above for guns. The 13-inch mortar requires one non-commissioned officer and five gunners; the 10-inch mortar one non-commissioned officer and four gunners; the 8-inch mortar one non-commissioned officer and three gunners; and the royal and cœhorn mortars one non-commissioned officer and two gunners each.

All calculations for the daily service of guns on batteries, whether in garrison or at a siege, should be made in three proportions and at three reliefs.

Numbering, Telling off the Detachments, an dFormation for Exercise.

The same in every respect as for field artillery.

Positions and Duties of the Numbers.

No. 1, directly in rear of the gun, points, commands, and assists to run the gun up; No. 2, on the right of and in line with the muzzle, sponges, runs up, and elevates; No. 3, on the left of the muzzle, and also in line with it, loads, runs up, and elevates; No. 4, on the right of the gun, clear of the track, and in line with the breech, serves the vent, primes, runs up, and traverses; No. 5, in the same relative position on the left of the gun, fires, runs up, and traverses; the remaining numbers on the right and left of the embrasure, with their backs to the merlons. No. 6 serves No. 3 with ammunition, and runs up; No. 7 assists to run up. The whole of the numbers, when not immediately employed in working the gun, should range themselves in order under cover of the parapet.

In serving mortars, No. 1 is directly in rear of the mortar, and points, commands, and serves the vent; No. 2, on the right of and in line with the front of the bed, sponges, runs up, and traverses; No. 3, in the same relative position on the left of the bed, loads, runs up, and traverses; No. 4, on the right of the mortar, covering No. 2, and in line with the vent, runs up, elevates, supplies shells, primes, and traverses; No. 5, in the same relative position on the left of the mortar, runs up, supplies shells, elevates, traverses, and fires; No. 6, at the magazine, serves ammunition. No. 2 puts the shells into the 8-inch royal and cœhorn mortars, and in putting them into the 13 and 10-inch mortars is assisted by No. 3.

3. *Exercise of the various Machines employed in the Manœuvres of Heavy Artillery.*

The method of numbering, telling off, &c., is the same in every respect for this branch of the exercises as for the two preceding, except that, in the exercise of the devil-carriage, the odd numbers are posted on the right side, and the even numbers on the left.

Exercise of the Triangle Gyn.

The complement of men for a triangle gyn is usually one non-commissioned officer and ten gunners. The following are the duties in working or carrying the gyn:

Left side.	*Right side.*
No. 3 carries at the foot of the left cheek, works the left-hand lever, keys and unkeys the left-hand capsquare of the gun-carriage, and assists to run the carriage up or back.	No. 2 carries at the foot of the right cheek, works the right-hand lever, keys and unkeys the right-hand capsquare of the gun-carriage, and assists to run the carriage up or back.
No. 5 carries at the top of the left cheek, works the left centre lever, and assists to run the carriage up or back.	No. 4 carries at the top of the right cheek, works the right centre lever, and assists to run the carriage up or back,
No. 7 carries the levers and handspikes, assists No. 6 in passing the fall round the windlass, and holds on next to him.	No. 6 carries the windlass. passes the fall round it, holds on, makes it fast, and eases off and lowers the gun.
No. 9 carries at the top of the pry-pole with the slings, fid, trucks, &c., holds on the fall behind No. 8, and coils it up as it comes off.	No. 8 carries at the foot of the pry-pole with the slings, fid, trucks, &c., and holds on next to No. 7.
No. 11 Assists in carrying the blocks and fall, reeves and unreeves the triple block, assists in slinging the gun, and steadies it at the muzzle.	No. 10 assists in carrying the blocks and fall, reeves and unreeves the double block, assists in slinging the gun, and steadies it at the cascable.

Exercise of Bell's Gyn.

This is a light gyn calculated to raise about 30 cwt. When greater weights are required to be raised, the Gibraltar Gyn is used, which is calculated to raise a weight of 50 cwt. with perfect safety. The duties of the Gibraltar Gyn are nearly identical with those of Bell's Gyn, which it has now replaced in the service. The complement of men for working it is one non-commissioned officer and six gunners.

Left side.	*Right side.*
No. 3 runs the carriage up or back, assists No. 6 in slinging the gun, turns the winch, assisted by No. 5, or makes fast and hauls upon the rope which is passed round the handles of the winch.	No. 2 runs the carriage up or back, assists No. 7 in slinging the gun, turns the winch assisted by No. 4, or holds on upon the rope and makes it fast, the same as No. 3.
No. 5 runs the carriage up or back, and assists No. 3 at the winch.	No. 4 performs similar duties to No. 5 on his own side.
No. 7 slings and unslings the gun at the chace, assisted by No. 2, and steadies at the muzzle.	No. 6 slings and unslings the gun at the first reinforce, assisted by No. 3, places the bed and quoin, and steadies the gun at the cascable.

Exercise of the Sling-cart.

The complement of men for a sling-cart is one non-commissioned officer and six gunners.

Left side.	*Right side.*
No. 3 has charge of the left lever, and when necessary assists to skid the gun.	No. 2 has charge of the right lever, and when necessary assists to skid the gun.
No. 5 assists No. 3 at the lever and skidding, and when the gun is lashed assists in raising the breech.	No. 4 in like manner assists No. 2, and when the gun is lashed assists in raising the breech.
No. 7 assists No. 3 at the lever, slings and unslings the gun, and lashes it to the pry-pole.	No. 6 assists No. 2 at the lever, slings and unslings the gun, and lashes it to the pry-pole.

The non-commissioned officer puts in and takes out the pauls, and commands.

Exercise of the Devil-carriage.

The complement of men for working this carriage is one non-commissioned officer and ten gunners.

Exercises.

Left side.	*Right side.*
No. 2 has charge of a drag-rope, assists in hauling the perch up and down, assists No. 3 in bearing the muzzle down, and, when the gun and carriage are lashed on, puts up the skid.	No. 3 has charge of a drag-rope, assists in hauling the perch up and down, bears the muzzle of the gun down, and, when the breech is raised, puts the lever into the muzzle.
No. 4 steadies the gun-carriage when raised on its breast transom, and with the long guy-rope lashes its front axle-tree to the devil-carriage.	No. 5. The duties of No. 5 are in all respects the same as those of No. 4.
No. 6 slings the gun, lashes the breech to the perch, assists in limbering up and unlimbering, and slings the gun-carriage.	No. 7. The duties of No. 7 are the same as those of No. 6, only performed on his own side of the carriage.
No. 8 has charge of one of the short guys, assists in unlimbering and limbering up, and in hauling the breech of the gun up to the perch; lashes the hind axle-tree of the gun-carriage to the devil-carriage, and fixes the long guy-rope to the iron eyes at the end of the perch.	No. 9 does the same as No. 8.
No. 10 assists in unlimbering and limbering up, and in hauling the breech of the gun up to the perch; lashes with the short guy-ropes the rear-axle-tree of the gun-carriage to the devil-carriage, and fixes the short guy-ropes to the ring under the perch.	No. 11 does the same as No. 10.

The several exercises which have been here explained afford but a very faint view of the admirable course of instruction which is assiduously and regularly carried on in the Royal Repository at Woolwich, and through which every gunner and every officer must necessarily pass. When it is considered that artillery men are required to handle heavy ordnance under circumstances sometimes of peculiar difficulty, and to provide for their transport sometimes up inclined planes, and sometimes over broken bridges or other obstructions, it will be readily conceived how important it must be that they should be fully and most carefully trained to the ready and skilful application of mechanical contrivances; and it is in this excellent establishment, now presided over by Colonel Hardinge, that they are experimentally made acquainted with them. All the military machines now in use, Pontons, models of various systems of temporary bridges, including the most simple as well as the more complex, are to be seen in the grounds or in the model-room; and every operation connected with them is taught practically at the establishment. It may then be confidently asserted, that much of the efficiency of the artillery is due to this branch of its instruction.

Rockets.

As this missile, though depending for its movement on the progressive or comparatively gradual combustion of an explosive, or rather highly inflammable compound, has been classed by all modern artillerists rather with ordnance than with the musket, or other more handy weapons of personal conflict, it is necessary to make some further remarks upon its application in war. But before doing so it is right to explain the principle of its movement, as the improvement of the rocket as an efficient projectile will depend greatly on a right understanding of this principle. Mariotte and Nollet ascribed the movement of the rocket to the re-action of the gas proceeding from the combustion of the powder, produced by the resistance of the air to its escape from the vent. Desaguliers and D'Antoni reject the instrumentality of the air, and consider the movement of the rocket to be solely due to the greater re-active force of the gases on the head of the rocket than on its base. The first theory appears to have been adopted in the Woolwich School of Artillery until very recently; but the latter, which is without doubt the true theory, is now taught by the present able inspector, a professor of artillery, Captain Boxer, R.A., and is fully adequate to explain the motion of rockets, and all similar cases of motion either in animals or in machines. A very few words will make it quite intelligible, and show that motion will be produced under such circumstances *in vacuo*, as well as in air or water. Let the case of the rocket be first considered as closed on every side; in this instance the gas formed by combustion will accumulate in the case, and exercise a pressure increasing with the increase of quantity, or the degree of compression to which it is subjected; but as the pressure will be equal in all directions, the rocket will be urged backwards with the same force that it is urged forwards, and hence must remain at rest. Let it be supposed, then, that the pressure on the head, and on the base of the rocket case is each equal to $(a + b)$ lb., and that a hole be then made in the base which will relieve a portion of the pressure equivalent to b lb., by allowing the gas to escape: the pressure now, on the head, will be $(a + b)$ lb., and on the base a lb., so that the rocket being impelled forwards by a force equal to $(a + b)$ lb., and backwards by a force of a lb., will be forced into motion by a resultant force equal to b lb. This resultant force, to induce motion, must be greater than the weight of the rocket, when the projectile is intended to be fired vertically, and greater than a weight equivalent to friction and inertia, when the projectile is intended to be fired horizontally.

The rocket, as an instrument of war, is associated in the English mind with the name of Congreve, although Sir William Congreve was not its inventor. The merit of that very able officer consists in his appreciation of the value of rockets, and in his ingenuity and skill in improving them. It is not improbable, that the Greek fire of the ancients may have been sometimes projected in the manner of rockets; and it is certain that in Asia they were used with other fireworks on days of public festivals at very remote epochs. M. de Montgery[1] has collected the following recorded examples of their use in war. By the Chinese in their wars with the Tartars, at the commencement of the thirteenth century; by the Paduans and Venetians in 1379 and 1380; by the French in 1428, in the defence of Orleans; and in 1449, in the attack upon Pont-Audemer, when Dunois threw rockets into the place and took it by assault during the confusion of the conflagration which followed. In 1561, it was stated that careful descriptions of flying and destructive fuses (rockets) were found in an ancient manuscript, and that it was recommended to *make their cases of sheet-iron*, and to varnish them as a security against rust. Louis Collado, the author of a *Manuel d'Artillerie*, states, in 1586, that rockets were used to light up the vicinity of besieged places, and to throw cavalry into confusion; and recommends that *a petard should be added to them*, in order to render them more dangerous, and that they should *be projected by means of a long tube*, in order to increase their range. Towards the end of the seventeenth century, and during the eighteenth, rockets appear to have fallen into disuse as weapons of war in Europe, although some experiments were made by Ruggieri, both on fire-rockets and on grenade rockets. In Asia they continued to be used, and at the siege of Seringapatam, were

[1] *Journal de Sciences Militaires*, 1825-26.

projected against the English troops with considerable effect. They were made of sheet iron, and provided with a stick or tail of bamboo. The idea of using rockets in war first occurred to Sir W. Congreve in 1804; but as he states the fact, that in India they had been already thus used, and that General Desaguliers had some years before made experiments upon them, it is manifest he did not claim the title of inventor, but merely claimed the merit of making them of large size, and bestowing upon them a sufficiently extended range, as he certainly did when he constructed one of 32 lb. weight, having an average range of 3000 yards. In 1806, they were first used by the English fleet against Boulogne; in 1807, against Copenhagen, under the superintendence of Congreve; in 1809, in the Walcheren expedition; and subsequently, with brilliant success at Leipzig, where the rocket troop, under the gallant Captain Bogue, who fell gloriously in the battle, distinguished itself. M. de Montgery remarks justly, that the rockets now called Congreve rockets, though at present looked upon as one of the most recent inventions in artillery, are, on the contrary, one of the most ancient. But at the same time he does full justice to Sir W. Congreve; for, as he observes, "Some persons in England and in France have disputed with that active and ingenious officer the invention of war rockets; but as they had been previously employed in Europe, and were still employed in Asia, he could only reasonably claim the merit of having revived their use and perfected their construction, and that he most undoubtedly did."

Of the importance of war rockets, Sir W. Congreve had the very highest opinion. He preferred their employment with infantry as ground rockets, and pointed out the fearful effects of a shower of 1000 such rockets, ploughing up the ground as they ricocheted along, and never rising for the first 400 yards above the height of a man. He pointed out their peculiar applicability to mountain warfare, and the ease with which they might be used by cavalry and in boats. He considered that they were superior to ordinary artillery, and even to shrapnel shells; both from the ease with which they could be transported and managed, and from the greater quantity of missiles which they could discharge in a given time. And, finally, he proposed to use them, not merely in defence, but also in the battery of attack for breaching, stating, that from his experiments, he was disposed to believe that rockets weighing from half a ton to a ton might be made and projected, and that such masses inclosed in cast-iron cases would, by their weight, penetrate into the *revêtement* of a fortress, and by their subsequent explosion effectually destroy it.

Without however concurring in all the expectations of Sir W. Congreve, or undervaluing the objections which have been urged against rockets, many of which may certainly be removed by improved construction, it may be fairly urged that the time has arrived when more attention ought to be paid to the construction and improvement of this valuable description of artillery, which may assuredly be used in positions and under circumstances where no other could be applied.

For the projection of case shot and of all missiles which should possess a penetrative power as well as an explosive force, the rocket possesses an advantage in long distances over the howitzer shell, as its velocity and penetrative force then exceeds those of a shell. M. de Montgery gives the following table exhibiting the velocities and penetrative power of a howitzer shell, 6 inches in diameter, weighing 23 lb., and projected at an angle of 40°, with a velocity of 950 feet per second, as compared with a rocket 3½ inches in diameter, and weighing with its stick 42 lb. in French measure.

Distances from the point of discharge.	Calculated Velocities.		Weight of the Rocket.	Penetrations in Earth by calculation.	
	Of the Shell.	Of the Rocket.		Of the Shell.	Of the Rocket.
Toises.	Feet.	Feet.	Pounds.	Feet.	Feet.
0	950	0	42	7·0	0·0
100	850	158	37	5·5	0·9
200	760	224	34	4·4	1·7
300	680	274	32	3·5	2·4
400	608	316	30	2·8	3·0
500	544	354	28	2·3	3·8
600	486	387	27	1·8	4·0
700	435	418	26	1·4	4·8
800	389	447	25	1·2	5·2
900	357	474	24	1·0	5·4
1000	338	500	23	0·9	5·7
1100	364	530	23	1·0	6·4
1200	385	565	23	1·1	7·3
1300	414	605	23	1·3	8·4
1400	451	650	23	1·6	9·7
1500	510	700	23	2·0	11·0

This Table, founded on calculation alone, can be only considered, in the present state of knowledge on the subject, of approximative value. It appears from it, that at 700 toises, or about 1400 yards, the velocities of the two projectiles are nearly the same, whilst the penetrative power of the rocket is more than three times greater than that of the shell, so that the rocket might be employed with great advantage in enfilading from great distances. When the distance is small the advantage is on the side of the shell, but at 800 yards the velocity and penetrative power are still quite sufficient to render heavy rockets most effective projectiles for any purpose; and with the knowledge that musketry will henceforth be effective at 600 yards, it is desirable that projectiles capable of fulfilling the functions of both musket and cannon should be brought into action at about that distance. In Denmark, under the directions of the late Captain Schumacher, brother of the celebrated astronomer, numerous and careful experiments were made with rockets, and it appears that shells, grenades, and case shot were successfully projected in connection with these projectiles, and were deemed so effective that rockets became a part of the recognised armament of the gun boats, and were combined with guns and howitzers in the field artillery used for the defence of the coast of Zealand. It was from information given by Captain Schumacher to Captain Brulard that rockets were for a short time introduced into the French artillery, but they do not seem to have subsequently made much progress in that country. In Austria the manufacture of rockets has been carried to the highest perfection; and it has been considered so important that the government has formed a large establishment near Vienna, Raketendorff, for the express purpose both of making and trying rockets, four companies of artificers organized for this particular duty being regularly trained and exercised within a vast inclosure attached to the establishment, the greatest secrecy being observed, and the public rigorously excluded from the premises.

The experiments of Captain Brulard were made by order of Marshal Davoust, who would have doubtless introduced this projectile into the French artillery, had not the course of military events been changed by the downfall of Napoleon. Marmont, another high military authority, has also given the following opinions in favour of rockets.[1]

"Every day the office of artillery in war is becoming more important, not merely on account of the augmentation of the number of guns, but also from their increased mobility, which enables them to enter into almost every military combination. There is, however, a limit to this mobility, and

[1] *L'Esprit des Institutions Militaires.*

the difficulty and expense of moving guns under some circumstances must operate materially to check their use in inordinate numbers. The maximum ought not, indeed, to be placed higher than 4 pieces of ordnance for 1000 men; but rockets form an artillery the possible development of which is so unlimited that they may well form a principal and distinct arm of the service. In fact, when it is remembered that the rocket generates within itself the propelling force, and requires no propellent machine, that it offers no tangible object to an enemy's fire, that it can be fired in any position, and under any circumstances, requiring neither platforms nor other preparation, and that it may be so multiplied as to cover the front of a single regiment with a shower of shot equivalent to the fire of 100 guns, it may be assumed that nothing could resist its destructive action, and that it would be ruinous to expose to its force troops drawn up in parallel lines on the field of battle. To adapt the infantry to the use of this missile, it should be divided into two sections, one provided with rockets and the other intended to act as a covering party, so that the infantry would become a kind of infantry-artillery. This new artillery would become more especially useful in all situations unfavourable to the use of guns, such as mountainous ground, the tops of buildings and churches, producing the effect of a powerful battery without trouble, and in an instant; and it is by its fire and extended use that an overpowering effect can alone be expected, as one or two rockets fired here and there would frighten more than hurt.

"In such considerations as these it is usual that everything should move on in a routine system, and modifications or improvements be so slowly arrived at that it may be long before the real power and value of Congreve rockets will be duly appreciated; but should an able general, endowed with foresight (for example a master-general of the ordnance), take up the subject in all its bearings, and quietly organize such a rocket establishment as will enable the arm to be applied in its fullest development on the field of battle, he will ensure for his countrymen success in succeeding conflicts, which must continue to be unequal until his enemy has adopted the same means of offence.

"I repeat that rockets are destined to effect a revolution in the art of war, and that success and glory will crown the efforts of him who has the genius first to comprehend and apply the advantages to be expected from them."

These observations of so able an officer deserve consideration, and the more so as the brilliant service of the rocket troop, under the gallant Captain Bogue, appears to have been the primary cause of that marked attention which has been subsequently paid to this arm by foreign governments. M. Montgery,[1] after pointing out the various objects which might be embraced in the use of rockets—and in doing so, he falls little, if at all, short of the expectations of Sir W. Congreve—combats the prejudices of his countrymen in the following terms:—"It is no longer a question as to the adoption of an arm of doubtful utility, as rockets have now been so much improved by the hands of foreigners, that they have acquired incontestibly an advantage over guns, carronades, howitzers, mortars, and ordinary projectiles, and it would be an extreme of fatuity not to make use of them. Great obstacles, however, are likely to be thrown in the way of their general introduction into our armies and fleets, as the soldiers and sailors likely to be consulted on such a subject are high in rank and grown old in a course of service where such projectiles were nearly unknown, and can scarcely be expected to abandon their prejudices against untried novelties, or to recommend their use." Let another result be hoped for the British army, and as Sir W. Congreve revived the use of the rocket in Europe, so let some other British artillery officer—and there are many of them possessed of scientific knowledge sufficient to undertake the task—undertake the further improvement of so important a projectile, and place it in its proper rank in British artillery.

An examination of the following table of iron ordnance, will show, that a great advance has been made in one material element of improvement, namely, simplification; as the number of calibres has been diminished by the abandonment of the 56, 42, and 9 pounder iron guns. Including the 10-inch and 8-inch guns, the number of calibres has been thus reduced to 8, and the wants of the marine service met, by adopting a variation in length and width to suit the capabilities of vessels, rather than a variety of calibre. Many, however, of the pieces which still appear on the list may be considered experimental, and will be hereafter replaced by others so adjusted as to meet all contingencies, and yet considerably reduce the number. As a general principle, the rule already laid down should be adhered to, namely, that for long ranges, where great precision of fire is the main object, a long and heavy gun is necessary; and for short ranges, where rapidity of fire becomes indispensable, a short and lighter gun; and, consequently, that the same calibre should be represented in both long and short guns.

A simplification of a different kind has been proposed by Colonel Timmermans, in the artillery of defence, the object of which is to do away with the distinction of gun and howitzer, by the introduction of a gun-howitzer, the calibre being regulated in reference to the size of the shells. He thus proposes for the armament of a fortress six pieces, namely:—

				Cwt.	Lb.
Mortars of 29 centimetres,	or $11\frac{1}{2}$ in. calibre,	and weighing		23	64
Light do. of 29 do.	or $11\frac{1}{2}$ in.	...	...	4	102
Howitzers of 20 ...	or $7\frac{9}{10}$ in.	...	...	58	104
Short do. of 20 ...	or $7\frac{9}{10}$ in.	...	...	23	64

Gun-howitzers of $13\frac{3}{4}$ centimetres, or $5\frac{4}{10}$, being the calibre of an 18-pounder; and weighing 22 cwt. 66 lb., or about the same as an iron 18-pounder of 7 feet in length.

Mortar of $13\frac{3}{4}$ centimetres, or $5\frac{4}{10}$, and weighing 0 cwt. 77 lb.; this latter piece being about the calibre of the British cohorn, with the weight of a royal, or $4\frac{2}{5}$ calibre mortar.

These are all bronze pieces, and would reduce the calibres to three, namely, $11\frac{4}{10}$, $7\frac{9}{10}$, $5\frac{4}{10}$, but the system requires the test of experiment; and as it does not include the guns of attack, nor even those guns which would secure the long range necessary for early coast defence, it can only be looked upon as suggestive. In like manner, the Emperor of the French has proposed a gun-howitzer for the field, and General Lewis[2] makes a suggestion in the same direction, when he remarks on one of the inconveniences of the howitzer construction,—"Difficulties," he says, "occur in siege batteries when the howitzer is used, in consequence of the muzzle not entering into the throat of the embrasure; the cheeks are then blown away, and the men exposed after a few rounds are fired. Two expedients might be adopted to remedy this inconvenience; either to provide for mounting the 8-inch howitzer on garrison carriages, or to *lengthen the piece* to 8 calibres, corresponding with the 68-pounder carronade; but this last plan would involve difficulties in building a travelling carriage of sufficient strength."

The lightness, also, of Colonel Timmermans' guns would produce a very powerful action on the carriages, and lead to an excessive recoil, when fired with tolerable charges; but this evil he proposes to diminish, by using a less rapidly igniting powder; and it may be observed that it does not enter into his scheme to fire with charges exceeding from $\frac{1}{4}$th to $\frac{1}{5}$th, or to attain initial velocities beyond 1300 feet for the solid shot of his $7\frac{9}{10}$ gun-howitzer, or 1381 feet for his $5\frac{4}{10}$ gun-howitzer; the principle he advocates being great momentum rather than great velocity.

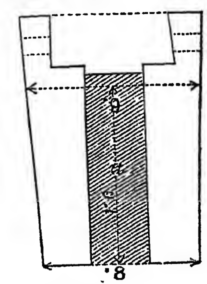
The improvement of the projectiles used is the next object of importance. The use of solid shot cannot be dispensed with, even when the action of artillery is directed against infantry, as the moral effect of its ravages is very great upon the soldier. Many modes, therefore, of increasing the precision of fire with such projectiles have been proposed, such as rifling the guns, covering the balls with lead or combining that metal with the iron in some other way so as to facilitate the rifling process, oval balls, &c.; and experiments are still in progress for the same purpose. But allowing every possible weight to the effects of solid shot, the shrapnel shell appears to be the most important and destructive projectile which has hitherto been invented for the purposes of war, as it combines the action of small shot with the extensive range of a cannon-ball or shell; and in the larger calibres, the moral effect of the cannon-ball might be secured in combination with its wide-spread action, by such a modification of the shell as would allow the use of large iron balls as in common case. At present, the effect of such projectiles may be understood from a consideration of the number of balls projected in each shell; thus—68-pounder, and 8-inch gun or howitzer, 377; 32-pounder, 204; 24-pounder, 128; 18-pounder, 90; 12-pounder, 63; 6-pounder, 27. One difficulty, however, attends the use of the shrapnel hitherto constructed; namely, the frequent ignition of the bursting powder, from the heat generated by friction between the balls; and the necessity, therefore, of using a diminished charge, with a corresponding loss in the extent of range. This evil it has been attempted to remedy by placing the powder in the centre of the balls; but the result of this arrangement is, that the balls receive an impulse from the bursting powder which may deflect them from their course, or even stop their further progress by neutralizing their remaining velocity. The most natural mode would appear to be a separation of the powder from the balls; a plan which was suggested about four years ago by Captain Boxer, R.A., but not then adopted by the artillery committee, who considered that a reduced charge was the simplest mode of lessening the chance of premature explosion, and did not, at that time, appear to think a great range so essential as it manifestly is. On the continent this plan has also been proposed; and the indefatigable inventor of it in this country has, by perseverance and skill, at length produced a shrapnel shell which may be fired with any amount of charge, and will be effective at any range. By its construction this shell will admit of the use of at least 1-lb. iron balls, and, as it may be fired even from mortars, the vertical fire of Carnot will no longer be an illusion, but will realize in its destructive effects the expectations of that author.

A shell, it will be observed, depends, as to the time of bursting, on the length of the fuse attached to it. The fuse is a short wooden pipe, somewhat like the wooden tap of a beer-barrel, being cylindrical within and slightly conical without; it is filled with a peculiar composition, and being driven or fixed into the fuse-hole of the shell, the priming ignites when the gun is fired, and on the composition burning through, the flame is communicated to the bursting powder within the shell, which then explodes. The time of bursting, therefore, depending on the length of fuse to be burnt, used to be regulated either by cutting the fuse to the required length in the field, or by boring out a portion of the composition; but these very rude systems will now be replaced by the simple but excellent fuse called Boxer's fuse, being another invention of that able and scientific officer. The beauty and simplicity of Captain Boxer's improvement of the fuse will be readily understood from the annexed woodcuts, the first of which represents the common shrapnel fuse, in which the time of burning has to be regulated by boring out a portion of the composition from the bottom of the fuse, and thus reducing the quantity to be burnt, and therefore the time of burning; the second, Boxer's fuse, in which a communication is made between the burning fuse composition and the bursting powder through the auxiliary tube *c*, by boring through the intervening side of the fuse (which is very easily done) at the proper opening *f*, corresponding to the required range, and marked on the external covering of the fuse. In this latter arrangement there can be no mistake, no chance of boring too much or too little, and no necessity of wasting time in guessing the quantity.

COMMON SHRAPNEL FUSE.

(*a*) Fuse composition which has to be bored out from the bottom for any particular range.



BOXER'S SHRAPNEL FUSE.

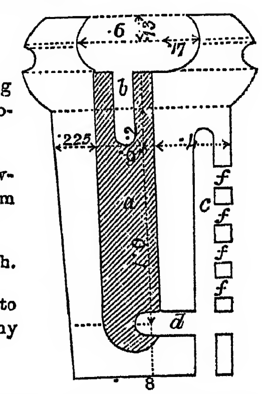
(*a*) Fuse composition.

(*b*) Small hole drilled through priming and composition, to insure the proper ignition of the fuse.

(*c*) Channel filled with fine grain-powder to communicate the fire from the fuse to the bursting powder.

(*d*) Side-hole containing quick-match.

(*f*, *f*, *f*) Side-holes to be continued into the composition in the field for any particular range.



Combining the improvement of the shrapnel shell and the improvement of the fuse, it may be reasonably expected that bursting in the gun or just beyond the muzzle, bursting at uncertain distances, and blind shells or shells bursting not at all, will cease to be the ordinary accidents of artillery practice.

On referring to the table of brass or bronze ordnance, it will be observed that the number of pieces is still considerable, being at least 12, and indeed sometimes reckoned as 13, whilst the number of calibres is 9, or may be reduced to 7 by classing together those of which the difference is small, and which may therefore be considered applicable for the propulsion of the same projectiles, with different degrees of windage. Such an arrangement renders it necessary to class together guns and howitzers of different calibre in the same battery, a system which, though now unavoidable, must be considered defective; the 24-pounder howitzer being classed with the 9-pounder in the field batteries, the 12-pounder howitzer with the 6-pounder in the horse or cavalry batteries, and the 32-pounder howitzer with the 12-pounder in batteries of position, so that the ammunition, case-shot, &c., of one cannot be used with the other. The present Emperor of the French has, indeed, in reference to these defects, proposed the adoption of a 12-pounder howitzer-gun as the single calibre to be used in the field; the weight being 11 cwt. 18 lb., or 2 cwt. 38 lb. less than the weight of the British 9-pounder. This howitzer-gun, mounted on the carriage of a French 8-pounder, corresponding nearly to a 9-pounder English, would, on account of its lightness, require to be fired

Artillery.

with a charge of one-fourth instead of one-third. The simplification thus effected would indeed be very important; but those who are well acquainted with the destructive effects on the carriage of firing from light guns, will at least require very careful preliminary experiments. As yet, in the British service, such experiments have not been considered favourable to the use of guns of diminished weight; but it may be possible that a howitzer-gun in weight between the 9-pounder and 12-pounder, and of the calibre of the 12-pounder, would be found efficient, with a reduced charge, for any service or range required in the field, or in movements of combined infantry and artillery.

Artillery.

In a preceding paragraph, the necessity of securing artillery from the effects of the fire at long ranges of the improved musket, by causing the guns to co-operate with riflemen, or with troops armed with this musket, has been strongly urged; and whilst in the press, the system of manœuvring artillery and infantry together, making the infantry the adjunct of the artillery, and not as heretofore the artillery the adjunct of the infantry, has been tried on a large scale at Vincennes; batteries having been thus formed in combined squares with the infantry, so that the latter could at once support the artillery and be supported by it. Such an experiment is an argument for securing an amount of speed or facility of movement equal to the most rapid movements of infantry, but not for going beyond that speed at the sacrifice of weight of metal; and it is equally an argument for obtaining a large calibre for the efficient use of spherical case. These conditions would probably be satisfied by a gun intermediate between the 9 and 12 pounder; as, for example, an 11-pounder, the calibre of which would be 4·5, therefore but little less than the calibre of a 12-pounder or a 10-pounder, the calibre of which would be about 4·35. Before closing these remarks, it may be well to reiterate the principles which have been already laid down as a guide in every attempt to improve field artillery; namely, 1*st*, that in the field or infantry batteries, the highest calibre consistent with a moderate degree of mobility; and, 2*d*, that in horse or cavalry artillery, the greatest speed consistent with a reasonable calibre—should be the objects sought for. All attempts to confound these principles together, will only lead to imperfect designs and ultimate failures in the field of actual service. It has, for example, been again proposed to replace the 6-pounder as a gun for the horse artillery by the 9-pounder; but the propriety of such an arrangement is at least very doubtful, as may be judged from the following considerations:—The weight of the 6-pounder with its limber, ammunition, and stores, is 28 cwt. 23 lb., and that of the 9-pounder, 38 cwt. 65 lb., being 10 cwt. 42 lb. more than the 6-pounder; or, as the weight of the two men carried on the limber will be common to both, the aggregate weights may be stated at 31 cwt. 23 lb. and 41 cwt. 65 lb.; the 9-pounder, therefore, exceeding the 6-pounder by about one-third of the whole weight of the former. At first sight it may be supposed that the addition of two horses (the number becoming six) will more than counterbalance this increase of weight, the power being in fact augmented by one-half instead of one-third; and unquestionably, on moderately level ground such as the common at Woolwich it would do so; but results of this kind are delusive when applied to other circumstances. Over rough ground the shocks to the carriage would be greatly increased by the additional weight, and in bad roads would so add to the strain on the horses that speed would often be impracticable. In passing over, also, such ground as must be frequently embraced by military operations, the traction will often fall entirely on the four rear horses, and sometimes even on the last two; and in such cases what must be the result of the increase of weight! Nor is this all, as the more the number of horses is increased, the more must the chances of being crippled by the loss of one or more horses be increased also; and it would, therefore, be better, were it possible to do so, to diminish the number of horses actually attached to the gun, and to keep more in reserve. In the ammunition waggons, also, that of the 9-pounder exceeds by about 5 cwt. that of the 6-pounder; and finally, it may be observed, that though an increase in the number of horses may under some circumstances keep up the required speed with a heavier gun; as a general rule, it will be found that the same analogy exists between the heavy and light gun as between the heavy and light coach, and that additional weight will therefore be moved either with a less velocity, or at the expense of frequent injury and destruction of both carriages and horses.

It is hoped that the perusal of this essay, though addressed rather to the general reader than to the more trained artillerist, will leave an impression on the mind of the great national importance of the arm of the service to which it relates, and of the necessity, as so strongly urged by one of its able members, Lieut. Jervis, in his work on *Tactics*, of establishing the training of its officers and men on a sound scientific basis. In all nations this has been felt, and schools of artillery and engineering have been established for the purpose of such training; a task confided in this country to the Royal Military Academy at Wool-

wich. On such a subject it might be supposed there could be little difference of opinion; but such is not the case, as some officers form a high estimate of the necessary qualifications of an artillery officer, looking not merely to the ordinary details of a parade or of a field-day, but to the knowledge which must be often called for in the many combinations and applications of so powerful an instrument of war; whilst others lower the standard of qualification, and because they have got through much rough work with honour, and yet with little science, maintain that the artillery officer may be made perfect without much theoretical knowledge. The true medium is between these extremes; for whilst the officer should not become too speculative, but be accustomed at every step of his theoretical education to refer his science to its practical application, he should never be allowed to think that ignorance of the science of his profession can be tolerated in the officer of such a corps. Let it also be remembered, that the great establishments of the arsenal, such as that of the inspector of artillery, of the royal carriage manufacture, and of the royal laboratory, are presided over by artillery officers, and yet are in their very essence eminently theoretical. The construction of a gun or of a carriage, and the manufacture of a rocket, of a fuse, or of a tube, are closely connected with theoretical questions of much delicacy; and it would be a mockery to expect that the departments under which they are conducted should keep pace with the progress of an age so distinguished for mechanical invention, unless presided over by men who add to their practical experience sound theoretical knowledge. Experiments may, indeed, be proposed and performed, alterations may be suggested and made, but few and far between will be the real improvements effected; and the British artillerist will be contented to follow where he ought to lead in the advancement of his profession. There is an academy, there are most able masters, there is every possible appliance of instruction, and at every half-yearly examination some few at least talented and well-instructed officers are poured into the regiment of artillery; but can it be said that any one of them who has distinguished himself for mathematical, mechanical, or chemical acquirements can speculate on becoming inspector or assistant-inspector of artillery, director of the laboratory, or fire-master? Here is the great mistake! ambition, as a natural stimulus to excel in those studies which have been partially mastered at the academy, and the hope of presiding over departments dependent upon them, are not applied; and too often a cold chill comes over the mind, and the pursuit of knowledge is abandoned as leading to no certain future distinction. Reverse this arrangement, and whilst a due amount of honour and reward is freely granted to the old and distinguished soldier, let none be appointed to scientific establishments who are not themselves scientific; and it will soon be found that the academy at Woolwich is fully able to raise up men who will do honour to their country, not only as brave and skilful gunners, but as sound theoretical artillerists. How long, indeed, would the service have struggled against the defects of the old fuse and the imperfections of the old shrapnel, had not an able scientific officer applied his mind and talents to the study of artillery in all its branches, and thus acquired the power of pointing out the mode of remedying them; and is it chimerical to anticipate far greater inventions, when the minds of many such officers shall have been directed to the same studies, and been encouraged to pursue them, to the ultimate benefit and perfection of their professional science?

(J. M. S.) (J. E. P.)

ARTILLERY was formerly applied in a collective sense to all kinds of offensive weapons; but this use of the word is now generally restricted to poetry.—See 1 *Samuel* xx. 40.

ARTILLERY Park. This term, introduced into military science, has been derived from the French verb *parquer*, to *separate from others, and keep together in an inclosure.* The great number and variety of carriages, horses, and stores of all kinds which must be connected with the equipment of artillery, render it necessary that they should be kept together, and not confusedly mixed up either with the troops or with the stores of other arms of the service; and this expressive term, therefore, at once states a fact, and explains the reason of it. Following up the analogy with a park for cattle or for deer, the artillery park has been sometimes inclosed with a rope-fence; and when in a dangerous position, not entirely free from the chance of surprise or of attack from cavalry, by a row of waggons united together by their drag-chains, or indeed by any other description of protective fence. In a large army the greater proportion of the ammunition and stores, the pontoon establishment, and even the artillery of reserve, may be best brought together in one large depôt or park, called the grand park, which should be located in the vicinity of proper roads, and so placed as to be protected on all sides from attack; its natural position is therefore either between the main body of the army and the reserve, or in the reserve itself. From this locality the artillery of reserve, or the pontoons, can be despatched to the division or divisions selected for any forward movement. If the army be of such magnitude as to include several aggregates of divisions, or corps d'armée, the grand park will be located in the rear, so as to minister to the wants of all; and a park of reserve will be formed with each. This park will be located with the reserve of the corps it accompanies, and should comprise a considerable body of reserve artillery, in addition to reserves of every description from the artillery of each separate division. A complete veterinary establishment and a pontoon train should be connected with it, and an ample establishment of artificers. In the grand park, and in parks of reserve, should the army continue stationary for any length of time, every care should be taken to secure the horses from the weather, and a proper infirmary established to receive sick horses from the divisions, or from the corps in advance.

In respect to the divisions of the army, each should be accompanied by two complete field batteries, and at least half a horse battery, provided the division be constituted of 10 battalions of 800 men each, and is supported in its independent movement by a due proportion of cavalry. If not acting independently, the division of infantry will have the two batteries, and the division of cavalry at least one battery. But in addition to the batteries acting in the field with the infantry, there ought to be artillery of reserve with each division. The French system was to divide their artillery into three sections, viz., the guns of the advanced guard, composed of 4-pounders ($4\frac{1}{4}$ English); the guns of the field of battle, composed of 8-pounders ($8\frac{3}{4}$ English); and guns of reserve, 12-pounders (13 pounders English); and as in the English service the light 6-pounder of the horse artillery may be considered a representative of the French 4, it may be supposed that the horse artillery, supported by cavalry, will move with the advance, and that the 12-pounder will act with the reserve. On this supposition, if two 12-pounders were added to each field battery, making the total number eight, as suggested under the article ARTILLERY, a field battery would consist of four 9-pounders, two 24-pounder howitzers, and two 12-pounders, of which the two 12-pounders ought to be in the divisional park of reserve. This park, placed sufficiently in rear of the division not to be incommoded by the enemy's fire, will contain not only the two reserve 12-pounders of each battery, or four 12-pounders in all, but also the spare ammunition waggons, spare carriages

and wheels, &c., the forge-cart of each battery, spare horses, and the pontoon train if the division be expected to move forward independently. In the artillery parks of reserve of each denomination the spare ammunition for the infantry should also be lodged; and, for the regulation of all the proceedings connected with the care and issue of such various stores and ammunition, the park is presided over by a regular staff, and should be provided with storekeepers, artificers, and labourers, in each separate department.

It will be observed, that the pontoon train is here supposed to be attached to the artillery as it is in the French army; in the British service it is attached to the engineer department, but the propriety of this latter arrangement is at least doubtful, for although every engineer officer, and every sapper and miner, should be well trained in the construction of pontoon, as well as of all other temporary or service bridges, it is manifest that the transport and care of the pontoons may be best confided to the artillery. In fact, it is very desirable that the pontoons should be put upon a proper footing as to horses and conductors; and that the horses and men connected with them should have been trained to guns, so that on an emergency both men and horses might take their places with the guns, and thus postpone as long as possible any diminution in the efficiency of that most important arm of the service. The pontoon horses could at any time be replaced by ordinary draught horses, but not so the artillery horses in the field. The engineer officer and the sapper and miner might still direct and assist in the construction of bridges, but the gunners and drivers attached to the pontoons should be men fully acquainted with all the details of every operation connected with it, from practical experience gained in the repository course.

The field-park or encampment is the last to be considered, and this should conform to the following general principles of encamping:—

1. The different regiments or corps are encamped in the same order as they are intended to fight, whether in the centre or the flanks, the first or second line.

2. The front of the encampment of each regiment or corps should occupy the space which it will require in battle; or, in other words, the line of tents of all the regiments or corps should cover the line of battle, so that on any necessity or alarm, whether by night or day, the troops, when forming in front of their tents, may find themselves in their proper places in the line of battle.

Now, as the relative positions in the field of battle of the troops of different arms must depend on the distinctive peculiarities of the ground to be occupied, the sites of the parks of artillery can only be determined after a careful examination or reconnaissance of that ground; but as a rule to be rigidly observed, it should be stated that artillery should never depend for its protection against surprise on its own men, and therefore should not be placed on the extreme flank. In ordinary ground, the battery or batteries attached to a division, with one ammunition waggon to each gun (the remaining waggons being sent to the park of reserve), should take up their position in rear of the division, each being opposite the interval between two brigades, so that the guns may be moved to the front at a moment's warning.

Several systems of parking have been adopted—1*st*, Parking to the rear or behind the guns: thus, guns at full distance, as in action, in front row; ammunition-waggons in second; horses picketed in the third; tents, one to each subdivision, in the fourth; tents of subaltern officers in the fifth; and captain's tent in the rear. 2*d*, Parking to the flanks: guns at half distance in front; horses for the guns picketed in the second row; waggons in the third, and horses for them in the fourth row,—the subdivision and other tents being placed on the flanks in files from front to rear. 3*d*, Parking to the front and flank, as sometimes practised in the French army, when the tents of the gunners are pitched in front of the guns, so that the men form a guard to the guns, and the tents of the drivers on the flanks. Again, the horses have sometimes been picketed on the flanks; but, generally speaking, all other systems may be considered modifications of the above. In the park of reserve the same rules should be followed, though occasional modification, as to a greater or lesser frontage, may be allowed, provided a due regularity in the classification of stores be preserved.

Between the brigades, or halves of brigades, an interval of about 110 or 120 yards should be preserved, as the proper per-centage for a six-gun battery; and, if possible, the battery should be covered on its flank by at least half a brigade. (J. E. P.)

Artillery Train, a certain number of pieces of ordnance mounted on carriages, with all their furniture fit for marching.

ARTIST, in a general sense, a person skilled in some art. Mr Harris defines an artist to be "a person possessing an habitual power of becoming the cause of some effect, according to a system of various and well-approved precepts." It is generally applied to an individual who practises the liberal arts as a profession.

ARTOCARPIÆ, a sub-order, established by Robert Brown, under the URTICEÆ. It contains the bread-fruit tree, *Artocarpus incisa*. See BOTANY.

ARTOIS, the name of an old province of France, of which Arras was the capital. With part of Picardy it now forms the department of Pas de Calais.

ARTOTYRITES (from ἄρτος, *bread*, and τυρός, *cheese*), a Christian sect in the primitive church, who celebrated the eucharist with bread and cheese, on the ground that the first oblations of men were not only of the fruits of the earth, but of their flocks. The Artotyrites admitted women to the priesthood and episcopacy; and Epiphanius tells us it was a common thing to see seven girls at once enter into their church, robed in white and holding a torch in their hand, where they wept and bewailed the wretchedness of human nature and the miseries of this life.

ARTS.

ART is defined by Lord Bacon as a proper disposal of the things of nature by human thought and experience, so as to answer the several purposes of mankind; in which sense *art* stands opposed to *nature*.

Art is principally used for a system of rules serving to facilitate the performance of certain actions; in which sense it stands opposed to *science*, or a system of speculative principles.

Arts are commonly divided into useful or mechanic, fine or liberal. The former are those wherein the hand and body are more concerned than the mind; of which kind are most of those which furnish us with the necessaries of life, and are popularly known by the name of trades. The latter are such as depend more on the labour of the mind than of the hand; they are the produce of imagination and taste, and their end is pleasure.

USEFUL ARTS.

Some useful arts must be nearly coeval with the human race; for food, clothing, and habitation, even in their original simplicity, require some art. Many other arts are of such antiquity as to place the inventors beyond the

Useful Arts.

reach of tradition. Several have gradually crept into the world without an inventor. The busy mind, however, accustomed to a beginning in things, cannot rest till it finds or imagines a beginning to every art. The most probable conjectures of this nature the reader may see in the historical introductions to the different articles. Lord Kames, in his *Sketches of the History of Man*, has given some curious illustrations of the progress of the arts.

In all countries where the people are barbarous and illiterate, the progress of arts is extremely slow. It is vouched by an old French poem, that the virtues of the loadstone were known in France before the year 1180. The mariner's compass was exhibited at Venice anno 1260, by Paulus Venetus, as his own invention. John Goya of Amalfi was the first who, many years afterwards, used it in navigation, and also passed for being the inventor. Though it was used in China for navigation long before it was known in Europe, yet to this day it is not so perfect as in Europe. Instead of suspending it in order to make it act freely, it is placed upon a bed of sand, in which position every motion of the ship disturbs its operation. Handmills, termed *querns*, were early used for grinding corn; and when corn came to be raised in greater quantity, horse-mills succeeded. Water-mills for grinding corn are described by Vitruvius. Wind-mills were known in Greece and in Arabia as early as the 7th century, and yet no mention is made of them in Italy till the 14th. That they were not known in England till the reign of Henry VIII. appears from a household book of an earl of Northumberland, contemporary with that king, stating an allowance for three mill-horses, "two to draw in the mill, and one to carry stuff to and from the mill." Water-mills for corn must in England have been of a later date. The ancients had mirror-glasses, and employed glass to imitate crystal vases and goblets; yet they never thought of using it in windows. In the 13th century the Venetians were the only people who had the art of making crystal glass for mirrors. A clock that strikes the hours was unknown in Europe till the end of the 12th century; and hence the custom of employing men to proclaim the hours during night. Galileo was the first who conceived an idea that a pendulum might be used for measuring time; and Huygens was the first who put the idea in execution, by making a pendulum clock. Hooke, in the year 1660, invented a spiral spring for a watch, though a watch was far from being a new invention. Paper was made no earlier than the 14th century; and the invention of printing was a century later. Silk manufactures were long established in Greece before silk-worms were introduced there. The manufacturers were provided with raw silk from Persia; but that commerce being frequently interrupted by war, two monks, in the reign of Justinian, brought eggs of the silk-worm from Hindostan, and taught their countrymen the method of managing them. The art of reading made a very slow progress: to encourage that art in England, the capital punishment for murder was remitted if the criminal could but read, which in law language is termed *benefit of clergy*. One would imagine that the arts must have made a very rapid progress when so greatly favoured: but there is a signal proof of the contrary; for so small an edition of the Bible as 600 copies, translated into English in the reign of Henry VIII., was not wholly sold off in three years.

The discoveries of the Portuguese on the west coast of Africa is a remarkable instance of the slow progress of arts. In the beginning of the 15th century they were totally ignorant of that coast beyond Cape Non, 28 degrees north latitude. In 1410 the celebrated Prince Henry of Portugal fitted out a fleet for discoveries, which proceeded along the coast to Cape Bajadore, in 28 degrees, but had not courage to double it. In 1418 Tristan Vaz discovered the island Porto Santo; and the year after the island Madeira was discovered. In 1439 a Portuguese captain doubled Cape Bajadore; and the next year the Portuguese reached Cape Blanco, lat. 20 degrees. In 1446 Nuna Tristan doubled Cape de Verde, lat. 14. 40. In 1448 Don Gonzallo Vallo took possession of the Azores. In 1449 the islands of Cape de Verde were discovered for Don Henry. In 1471 Pedro d'Escovar discovered the island St Thomas and Prince's Island. In 1484 Diego Cam discovered the kingdom of Congo. In 1486 Bartholomew Diaz, employed by John II. of Portugal, doubled the Cape of Good Hope, which he called *Cabo Tormentoso*, from the tempestuous weather he found in the passage.

The progress of art seldom fails to be rapid when a people happen to be roused out of a torpid state by some fortunate change of circumstances. Prosperity, contrasted with former abasement, gives to the mind a spring, which is vigorously exerted in every new pursuit. The Athenians made but a mean figure under the tyranny of Pisistratus, but upon regaining freedom and independence they were converted into heroes. Miletus, a Greek city of Ionia, being destroyed by the king of Persia, and the inhabitants made slaves, the Athenians, deeply affected with the misery of their brethren, boldly attacked the king in his own dominions, and burnt the city of Sardis. In less than ten years after, they gained a signal victory at Marathon; and, under Themistocles, made head against that prodigious army with which Xerxes threatened utter ruin to Greece. Such prosperity produced its usual effects: arts flourished with arms, and Athens became the chief theatre for sciences, as well as for fine arts. The reign of Augustus Cæsar, which put an end to the rancour of civil war, and restored peace to Rome, with the comforts of society, proved an auspicious era for literature, and produced a cloud of Latin historians, poets, and philosophers, to whom the moderns are indebted for their taste and talents. One who makes a figure rouses emulation in all: one catches fire from another, and the national spirit is everywhere triumphant; classical works are composed, and useful discoveries made in every art and science. With regard to Rome, it is true that the Roman government under Augustus was in effect despotic; but despotism in that single instance made no obstruction to literature, it having been the policy of that reign to hide power as much as possible. A similar revolution happened in Tuscany about three centuries ago. That country having been divided into a number of small republics, the people, excited by mutual hatred between small nations in close neighbourhood, became ferocious and bloody, flaming with revenge for the slightest offence. These republics being united under the great duke of Tuscany, enjoyed the sweets of peace in a mild government. That comfortable revolution, which made the deeper impression by a retrospect of recent calamities, roused the national spirit, and produced ardent application to arts and literature. The restoration of the royal family in England, which put an end to a cruel and envenomed civil war, promoted improvements of every kind; arts and industry made a rapid progress among the people, though left to themselves by a weak and fluctuating administration. Had the nation, upon that favourable turn of fortune, been blessed with a succession of able and virtuous princes, to what a height might not arts and sciences have been carried!

Another cause of activity and animation is the being engaged in some important action of doubtful issue,—a struggle for liberty, the resisting a potent invader, or the like. Greece, divided into small states frequently at war with each other, advanced literature and the fine arts to

unrivalled perfection. The Corsicans, while engaged in a perilous war for defence of their liberties, exerted a vigorous national spirit; they founded a university for arts and sciences, a public library, and a public bank. After a long stupor during the dark ages of Christianity, arts and literature revived among the turbulent states of Italy. The Royal Society in London, and the Academy of Sciences in Paris, were both of them instituted after civil wars that had animated the people and roused their activity.

In a country thinly peopled, where even necessary arts want hands, it is common to see one person exercising more arts than one. In every populous country, even simple arts are split into parts, and each part has an artist appropriated to it. In the large towns of ancient Egypt a physician was confined to a single disease. In mechanic arts that method is excellent. As a hand confined to a single operation becomes both expert and expeditious, a mechanic art is perfected by having its different operations distributed among the greatest number of hands: many hands are employed in making a watch, and a still greater number in manufacturing a web of woollen cloth. Various arts or operations carried on by the same man invigorate his mind, because they exercise different faculties; and as he cannot be equally expert in every art or operation, he is frequently reduced to supply want of skill by thought and invention. Constant application, on the contrary, to a single operation, confines the mind to a single object, and excludes all thought and invention. In such a train of life the operator becomes dull and stupid, like a beast of burden. The difference is visible in the manners of the people. In a country where, from want of hands, several occupations must be carried on by the same person, the people are knowing and conversable: in a populous country, where manufactures flourish, they are ignorant and unsociable. The same effect is equally visible in countries where an art or manufacture is confined to a certain class of men. It is visible in Hindostan, where the people are divided into castes, which never mix even by marriage, and where every man follows his father's trade. The Dutch lint-boors are a similar instance: the same family carries on the trade from generation to generation, and are accordingly ignorant and brutish even beyond other Dutch peasants.

Useful arts pave the way to fine arts. Men upon whom the former had bestowed every convenience, turned their thoughts to the latter. Beauty was studied in objects of sight; and men of taste attached themselves to the fine arts, which multiplied their enjoyments and improved their benevolence. Sculpture and painting made an early figure in Greece, which afforded plenty of beautiful originals to be copied in these imitative arts. Statuary, a more simple imitation than painting, was sooner brought to perfection. The statue of Jupiter by Phidias, and of Juno by Polycletes, though the admiration of all the world, were executed long before the art of light and shade was known. Apollodorus, and Zeuxis his disciple, who flourished in the 95th olympiad, were the first who figured in that art. Another cause concurred to advance statuary before painting in Greece, viz. a great demand for statues of their gods. Architecture, as a fine art, made a slower progress. Proportions, upon which its elegance chiefly depends, cannot be accurately ascertained, but by an infinity of trials in great buildings. A model cannot be relied on; for a large and a small building, even of the same form, require different proportions.

FINE ARTS.

The term Fine Arts may be viewed as embracing all those arts in which the powers of imitation or invention are exerted, chiefly with a view to the production of pleasure by the immediate impression which they make on the mind. But the phrase has of late, we think, been restricted to a narrower and more technical signification; namely, to painting, sculpture, engraving, and architecture, which appeal to the eye as the medium of pleasure; and, by way of eminence, to the two first of these arts. In the following observations we shall adopt this limited sense of the term; and shall endeavour to develope the principles upon which the great masters have proceeded, and also to inquire, in a more particular manner, into the state and prospects of these arts in this country.

The great works of art at present extant, and which may be regarded as models of perfection in their several kinds, are the remains of classic art, consisting chiefly of sculpture—the pictures of the celebrated Italian masters—those of the old German and the Dutch and Flemish schools—to which we may add the comic productions of our own countryman Hogarth. These all stand unrivalled in the history of art; and they owe their pre-eminence and perfection to one and the same principle,—*the immediate imitation of nature.* This principle predominated equally in the classical forms of the antique and in the grotesque figures of Hogarth: the perfection of art in each arose from the truth and identity of the imitation with the reality; the difference was in the subjects—there was none in the mode of imitation. Yet the advocates for the *ideal system of art* would persuade their disciples, that the difference between Hogarth and the antique does not consist in the different forms of nature which they imitated, but in this, that the one is like and the other unlike nature. This is an error the most detrimental perhaps of all others, both to the theory and practice of art. As, however, the prejudice is very strong and general, and supported by the highest authority, it will be necessary to go somewhat elaborately into the question in order to produce an impression on the other side.

What has given rise to the common notion of the *ideal*, as something quite distinct from *actual* nature, is probably the perfection of the Greek statues. Not seeing among ourselves any thing to correspond in beauty and grandeur, either with the features or form of the limbs in these exquisite remains of antiquity, it was an obvious, but a superficial conclusion, that they must have been created from the idea existing in the artist's mind, and could not have been copied from any thing existing in nature. The contrary, however, is the fact. The general form, both of the face and figure, which we observe in the old statues, is not an ideal abstraction, is not a fanciful invention of the sculptor, but is as completely local and national (though it happens to be more beautiful) as the figures on a Chinese screen, or a copperplate engraving of a negro chieftain in a book of travels. It will not be denied that there is a difference of physiognomy as well as of complexion in different races of men. The Greek form appears to have been naturally beautiful, and they had, besides, every advantage of climate, of dress, of exercise, and modes of life to improve it. The artist had also every facility afforded him in the study and knowledge of the human form; and their religious and public institutions gave him every encouragement in the prosecution of this art. All these causes contributed to the perfection of these noble productions; but we should be inclined principally to attribute the superior symmetry of form common to the Greek statues, in the first place, to the superior symmetry of the models in nature; and in the second, to the more constant opportunities for studying them. If we allow, also, for the superior genius of the people, we shall not be wrong; but this superiority consisted in their peculiar susceptibility to the impres-

sions of what is beautiful and grand in nature. It may be thought an objection to what has just been said, that the antique figures of animals, &c., are as fine, and proceed on the same principles, as their statues of gods or men. But all that follows from this seems to be, that their art had been perfected in the study of the human form, the test and proof of power and skill; and was then transferred easily to the general imitation of all other objects, according to their true characters, proportions, and appearances. As a confirmation of these remarks, the antique portraits of individuals were often superior even to the personifications of their gods. We think that no unprejudiced spectator of real taste can hesitate for a moment in preferring the head of the Antinous, for example, to that of the Apollo. And in general it may be laid down as a rule, that the most perfect of the antiques are the most simple,—those which affect the least action, or violence of passion,—which repose the most on natural beauty of form, and a certain expression of sweetness and dignity, that is, which remain most nearly in that state in which they could be copied from nature without straining the limbs or features of the individual, or racking the invention of the artist. This tendency of Greek art to repose has indeed been reproached with insipidity by those who had not a true feeling of beauty and sentiment. We, however, prefer these models of habitual grace or internal grandeur to the violent distortions of suffering in the Laocoon, or even to the supercilious air of the Apollo. The Niobe, more than any other antique head, combines truth and beauty with deep passion. But here the passion is fixed, intense, habitual;—it is not a sudden or violent gesticulation, but a settled mould of features; the grief it expresses is such as might almost turn the human countenance itself *into marble!*

In general, then, we would be understood to maintain, that the beauty and grandeur so much admired in the Greek statues were not a voluntary fiction of the brain of the artist, but existed substantially in the forms from which they were copied, and by which the artist was surrounded. A striking authority in support of these observations, which has in some measure been lately discovered, is to be found in the *Elgin marbles*, taken from the Acropolis at Athens, and now universally admitted to be the work of Phidias. The process of fastidious refinement and indefinite abstraction is certainly not visible there. The figures have all the ease, the simplicity, and variety, of individual nature. Even the details of the subordinate parts, the loose hanging folds in the skin, the veins under the belly or on the sides of the horses, more or less swelled as the animal is more or less in action, are given with scrupulous exactness. This is true nature and true art. In a word, these invaluable remains of antiquity are precisely like casts taken from life. The *ideal* is not the preference of that which exists only in the mind to that which exists in nature; but the preference of that which is fine in nature to that which is less so. There is nothing fine in art but what is taken almost immediately, and, as it were, in the mass, from what is finer in nature. Where there have been the finest models in nature, there have been the finest works of art.

As the Greek statues were copied from Greek forms, so Raphael's expressions were taken from Italian faces; and we have heard it remarked, that the women in the streets at Rome seem to have walked out of his pictures in the Vatican.

Sir Joshua Reynolds constantly refers to Raphael as the highest example in modern times (at least with one exception) of the grand or ideal style; and yet he makes the essence of that style to consist in the embodying of an abstract or general idea, formed in the mind of the artist by rejecting the peculiarities of individuals, and retaining only what is common to the species. Nothing can be more inconsistent than the style of Raphael with this definition. In his Cartoons, and in his groupes in the Vatican, there is hardly a face or figure which is any thing more than fine individual nature finely disposed and copied. The painter Barry, who could not be suspected of prejudice on this side of the question, speaks thus of them: "In Raphael's pictures (at the Vatican) of the *Dispute of the Sacrament*, and the *School of Athens*, one sees all the heads to be entirely copied from particular characters in nature, nearly proper for the persons and situations which he adapts them to; and he seems to me only to add and take away what may answer his purpose in little parts, features, &c.; conceiving, while he had the head before him, ideal characters and expressions, which he adapts these features and peculiarities of face to. This attention to the particulars which distinguish all the different faces, persons, and characters, the one from the other, gives his pictures quite the verity and unaffected dignity of nature, which stamp the distinguishing differences betwixt one man's face and body and another's."

If any thing is wanting to the conclusiveness of this testimony, it is only to look at the pictures themselves; particularly the *Miracle of the Conversion*, and the *Assembly of Saints*, which are little else than a collection of divine portraits, in natural and expressive attitudes, full of the loftiest thought and feeling, and as varied as they are fine. It is this reliance on the power of nature which has produced those masterpieces by the prince of painters, in which expression is all in all;—where one spirit—that of truth—pervades every part, brings down heaven to earth, mingles cardinals and popes with angels and apostles,—and yet blends and harmonizes the whole by the true touches and intense feeling of what is beautiful and grand in nature. It is no wonder that Sir Joshua, when he first saw Raphael's pictures in the Vatican, was at a loss to discover any great excellence in them, if he was looking out for his theory of the *ideal*,—of neutral character and middle forms.

There is more an appearance of abstract grandeur of form in Michael Angelo. He has followed up, has enforced, and expanded, as it were, a preconceived idea, till he sometimes seems to tread on the verge of caricature. His forms, however, are not *middle*, but *extreme* forms, massy, gigantic, supernatural. They convey the idea of the greatest size and strength in the figure, and in all the parts of the figure. Every muscle is swollen and turgid. This tendency to exaggeration would have been avoided if Michael Angelo had recurred more constantly to nature, and had proceeded less on a scientific knowledge of the structure of the human body; for science gives only the positive form of the different parts, which the imagination may afterwards magnify as it pleases; but it is nature alone which combines them with perfect truth and delicacy, in all the varieties of motion and expression. It is fortunate that we can refer, in illustration of our doctrine, to the fragment of the Theseus in the British Museum, which shows the possibility of uniting the grand and natural style in the highest degree. The form of the limbs, as affected by pressure or action, and the general sway of the body, are preserved with the most consummate mastery. We should prefer this statue as a model for forming the style of the student to the Apollo, which strikes us as having something of a theatrical appearance; or to the Hercules, in which there is an ostentatious and over-laboured display of anatomy. This last figure is so overloaded with sinews, that it has been suggested as a doubt, whether, if life could be put into it, it would be able to move. Grandeur of conception, truth of nature, and pu-

rity of taste, seem to have been at their height when the masterpieces which adorned the Temple of Minerva at Athens, of which we have only these imperfect fragments, were produced. Compared with these, the later Greek statues display a more elaborate workmanship, more of the artifices of style. The several parts are more uniformly balanced, made more to tally like modern periods; each muscle is more equally brought out, and more highly finished as a part, but not with the same subordination of each part to the whole. If some of these wonderful productions have a fault, it is the want of that entire and naked simplicity which pervades the whole of the *Elgin marbles*.

Works of the Grecian and Italian artists.

Having spoken here of the Greek statues, and of the works of Raphael and Michael Angelo, as far as relates to the imitation of nature, we shall attempt to point out, to the best of our ability, and as concisely as possible, what we conceive to be their general and characteristic excellences. The ancients excelled in beauty of form; Michael Angelo in grandeur of conception; Raphael in expression. In Raphael's faces, particularly his women, the expression is very superior to the form; in the ancient statues the form is the principal thing. The interest which the latter excite is in a manner external; it depends on a certain grace and lightness of appearance, joined with exquisite symmetry and refined susceptibility to voluptuous emotions; but there is in general a want of pathos. In their looks we do not read the workings of the heart; by their beauty they seem raised above the sufferings of humanity; by their beauty they are deified. The pathos which they exhibit is rather that of present and physical distress, than of deep internal sentiment. What has been remarked of Lionardo da Vinci, is also true of Raphael, that there is an angelic sweetness and tenderness in his faces, in which human frailty and passion are purified by the sanctity of religion. The ancient statues are finer objects for the eye to contemplate; they represent a more perfect race of physical beings, but we have little sympathy with them. In Raphael, all our natural sensibilities are heightened and refined by the sentiments of faith and hope, pointing mysteriously to the interests of another world. The same intensity of passion appears also to distinguish Raphael from Michael Angelo. Michael Angelo's forms are grander, but they are not so informed with expression. Raphael's, however ordinary in themselves, are full of expression, " even to o'erflowing;" every nerve and muscle is impregnated with feeling,—bursting with meaning. In Michael Angelo, on the contrary, the powers of body and mind appear superior to any events that can happen to them; the capacity of thought and feeling is never full, never strained or tasked to the extremity of what it will bear. All is in a lofty repose and solitary grandeur, which no human interest can shake or disturb. It has been said that Michael Angelo painted *man*, and Raphael *men*; that the one was an epic, the other a dramatic painter. But the distinction we have stated is, perhaps, truer and more intelligible, viz., that the one aimed at greater dignity of form, and the other gave greater force and refinement of expression. Michael Angelo, in fact, formed his ideas on classic art, in favour of which an enthusiastic feeling had arisen in his time, many of the finest specimens of the works of the ancients having been then first brought to light; his style, therefore, is based very much on sculpture, and is characterized by grandeur and severity—nevertheless his works possess much that is picturesque. The whole figure of his *Jeremiah* droops and hangs down like a majestic tree surcharged with showers. His drawing of the human form has the characteristic freedom and boldness of Titian's landscapes.

After Michael Angelo and Raphael, there is no doubt that Lionardo da Vinci and Coreggio are the two painters, in modern times, who have carried historical expression to the highest ideal perfection; and yet it is equally certain that their heads are carefully copied from faces and expressions in nature. Lionardo excelled principally in his women and children. We find, in his female heads, a peculiar charm of expression; a character of natural sweetness and tender playfulness, mixed up with the pride of conscious intellect and the graceful reserve of personal dignity. He blends purity with voluptuousness; and the expression of his women is equally characteristic of " the mistress or the saint." His pictures are worked up to the height of the idea he had conceived, with an elaborate felicity; but this idea was evidently first suggested, and afterwards religiously compared with nature. This was his excellence. His fault is, that his style of execution is too mathematical; that is, his pencil does not follow the graceful variety of the details of objects, but substitutes certain refined gradations, both of form and colour, producing equal changes in equal distances, with a mechanical uniformity. Lionardo was a man of profound learning as well as genius, and perhaps transferred too much of the formality of science to his favourite art.

The masterpieces of Coreggio have the same identity with nature, the same stamp of truth. He has indeed given to his pictures the utmost softness and refinement of outline and expression; but this idea, at which he constantly aimed, is filled up with all the details and varieties which such heads would have in nature. So far from any thing like a naked abstract idea, or middle form, the *individuality* of his faces has something peculiar in it, even approaching the grotesque. He has endeavoured to impress habitually on the countenance those undulating outlines which rapture or tenderness leave there, and has chosen for this purpose those forms and proportions which most obviously assisted his design.

As to the colouring of Coreggio, it is nature itself. Not only is the general tone perfectly true, but every speck and particle is varied in colour, in relief, in texture, with a care, a felicity, and an effect, which is almost magical. His light and shade are equally admirable. No one else, perhaps, ever gave the same harmony and roundness to his compositions. So true are his shadows,—equally free from coldness, opacity, or false glare;—so clear, so broken, so airy, and yet so deep, that if you hold your hand so as to cast a shadow on any part of the flesh which is in the light, this part, so shaded, will present exactly the same appearance which the painter has given to the shadowed part of the picture. Coreggio, indeed, possessed a greater variety of excellences in the different departments of his art than any other painter; and yet it is remarkable, that the impression which his pictures leave upon the mind of the common spectator is monotonous and comparatively feeble. His style is in some degree mannered and confined. For instance, he is without the force, passion, and grandeur of Raphael, who, however, possessed his softness of expression, but of expression only; and in colour, in light and shade, and some other qualities, was perhaps not equal to Coreggio. We may, perhaps, solve this apparent contradiction by saying, that he applied the power of his mind to a greater variety of objects than others; but that this power was still of the same character; consisting in a certain exquisite sense of the harmonious, the soft and graceful in form, colour, and sentiment, but with a deficiency of strength, and a tendency to effeminacy in all these.

It was at one time the fashion after Raphael and Coreggio to mention Guido, whose female faces are exceedingly beautiful and ideal, but altogether commonplace and vapid compared with those of Raphael or Coreggio; and

for no other reason but that the general idea they convey is not enriched and strengthened by an intense contemplation of nature. For the same reason, we can conceive nothing more unlike the antique than the figures of Nicholas Poussin, except as to the preservation of the costume; and it is perhaps chiefly owing to the habit of studying his art at second-hand, or by means of scientific rules, that the great merits of that able painter, whose understanding and genius are unquestionable, are confined to his choice of subjects for his pictures, and his manner of telling the story. His landscapes, which he probably took from nature, are superior as paintings to his historical pieces. The faces of Poussin want natural expression, as his figures want grace; but the back-grounds of his historical compositions can scarcely be surpassed. In his *Plague of Athens*, the very buildings seem stiff with horror. His giants, seated on the top of their fabled mountains, and playing on their Pan pipes, are as familiar and natural as if they were the ordinary inhabitants of the scene. The finest of his landscapes is his picture of the *Deluge*. The sun is just seen, wan and drooping in his course. The sky is bowed down with a weight of waters, and heaven and earth seem mingling together.

Titian is at the head of the Venetian school. He is the first of all colourists. In delicacy and purity Coreggio is equal to him, but his colouring has not the same warmth and gusto in it. Titian's flesh-colour partakes of the glowing nature of the climate, and of the luxuriousness of the manners of his country. He represents objects not through a merely lucid medium, but as if tinged with a golden light. Yet it is wonderful in how low a tone of local colouring his pictures are painted,—how rigidly his means are husbanded. His most gorgeous effects are produced, not less by keeping down than by heightening his colours; the fineness of his gradations adds to their variety and force; and, with him, truth is the same thing as splendour. Every thing is done by the severity of his eye, by the patience of his touch. He is enabled to keep pace with nature by never hurrying on before her; and as he forms the broadest masses out of innumerable varying parts and minute strokes of the pencil, so he unites and harmonizes the strongest contrasts by the most imperceptible transitions. Every distinction is relieved and broken by some other intermediate distinction, like half-notes in music; and yet all this accumulation of endless variety is so managed as only to produce the majestic simplicity of nature, so that to a common eye there is nothing extraordinary in his pictures, any more than in nature itself. It is, we believe, owing to what has been here stated, that Titian is, of all painters, at once the easiest and the most difficult to copy. He is the most difficult to copy perfectly, for the artifice of his colouring and execution is hid in its apparent simplicity; and yet the knowledge of nature, and the arrangement of the forms and masses in his pictures, are so masterly, that any copy made from them, even the rudest outline or sketch, can hardly fail to have a look of high art. Because he was the greatest colourist in the world, this, which was his most prominent, has, for shortness, been considered as his only excellence; and he has been said to have been ignorant of drawing. What he was, generally speaking, deficient in, was invention or composition, though even this appears to have been more from habit than want of power; but his drawing of actual forms, where they were not to be put into momentary action, or adapted to a particular expression, was as fine as possible. His drawing of the forms of inanimate objects is unrivalled. His trees have a marked character and physiognomy of their own, and exhibit an appearance of strength or flexibility, solidity or lightness, as if they were endued with conscious power and purposes. Character was another excellence which Titian possessed in the highest degree. It is scarcely speaking too highly of his portraits to say, that they have as much expression, that is, convey as fine an idea of intellect and feeling, as the historical heads of Raphael. The chief difference appears to be, that the expression in Raphael is more imaginary and contemplative, and in Titian more personal and constitutional. The heads of the one seem thinking more of some event or subject, those of the other to be thinking more of themselves. In the portraits of Titian, as might be expected, the Italian character always predominates; there is a look of piercing sagacity, of commanding intellect, of acute sensibility, which it would be in vain to seek for in any other portraits. The daring spirit and irritable passions of the age and country are distinctly stamped upon their countenances, and can be as little mistaken as the costume which they wear. The portraits of Raphael, though full of profound thought and feeling, have more of common humanity about them. Titian's portraits are the most historical that ever were painted; and they are so for this reason, that they have most consistency of form and expression. His portraits of Hippolito de' Medici, and of a young Neapolitan nobleman, lately in the gallery of the Louvre, are a striking contrast in this respect. All the lines of the face in the one, the eye-brows, the nose, the corners of the mouth, the contour of the face, present the same sharp angles, the same acute, edgy, contracted, violent expression. The other portrait has the finest expansion of feature and outline, and conveys the most exquisite idea possible of mild, thoughtful sentiment. The consistency of the expression constitutes as great a charm in Titian's portraits as the harmony of the colouring. The similarity sometimes objected to his heads is partly national, and partly arises from the class of persons whom he painted. He painted only Italians; and in his time it rarely happened that any but persons of the highest rank, senators or cardinals, sat for their pictures. The similarity of costume of the dress, the beard, &c. also adds to the similarity of their appearance. It adds at the same time to their picturesque effect; and the alteration in this respect is one circumstance among others that has been injurious, not to say fatal, to modern art. This observation is not confined to portrait; for the hired dresses with which our historical painters clothe their figures sit no more easily on the imagination of the artist, than they do gracefully on the lay-figures over which they are thrown.

Giorgione, Paul Veronese, and Tintoret, are the remaining great names of the Venetian school. Their excellence consisted in bold, masterly and striking imitation of nature. Giorgione takes the first place among them; for he was the fellow-pupil and rival of Titian, whereas the others were only his disciples. His works, besides, are highly valued for their grandeur and dignity and for their poetical treatment, generally involving some deep allegorical meaning. The Caraccis, Domenichino, Guido, Guercino, and Albani, who established, after the decline of Italian art, what is generally styled the Bolognese school, formed themselves on the principle of combining the excellences of the Roman and Venetian painters; they flourished for a time, but at last degenerated into absolute insignificance, in proportion as they departed from nature, or the great masters who had copied her, to mould their works on academic rules, and the phantoms of abstract perfection.

Flemish and Dutch painters.

Rubens is the prince of the Flemish painters. Of all the great painters, he is perhaps the most artificial,—the one who painted most from his own imagination,—and, what was almost the inevitable consequence, the most of a mannerist. He had neither the Greek forms to study

from, nor the Roman expression, nor the high character, picturesque costume, and sun-burnt hues which the Venetian painters had immediately before them. He took, however, what circumstances presented to him,—a fresher and more blooming tone of complexion, arising from moister air and a colder climate. To this he added the congenial splendour of reflected lights and shadows cast from rich drapery; and he made what amends he could for the want of expression, by the richness of his compositions, and the fantastic variety of his allegorical groups. Both his colouring and his drawing were, however, ideal exaggerations. But both had particular qualities of the highest value. He has given to his flesh greater transparency and freshness than any other painter; and this excellence he had from nature. One of the finest instances will be found in his *Peasant Family going to Market*, in which the figures have all the bloom of health upon their countenances; and the very air of the surrounding landscape strikes sharp and wholesome on the sense. Rubens had another excellence; he has given all that relates to the expression of motion in his allegorical figures, in his children, his animals, even in his trees, to a degree which no one else has equalled, or indeed approached. His drawing is often deficient in proportion, in knowledge, and in elegance, but it is always picturesque. The drawing of N. Poussin, on the contrary, which has been much cried up, is merely learned and anatomical: he has a knowledge of the structure and measurements of the human body, but very little feeling of the grand, or beautiful, or striking in form. All Rubens' forms have ease, freedom, and excessive elasticity. In the grotesque style of history,—as in the groups of satyrs, nymphs, bacchanals, and animals, where striking contrasts of form are combined with every kind of rapid and irregular movement,—he has not a rival. Witness his Silenus at Blenheim, where the lines seem drunk and staggering; and his procession of Cupids riding on animals at Whitehall, with that adventurous leader of the infantine crew, who, with a spear, is urging a lion, on which he is mounted, over the edge of the world; for beyond we only see a precipice of clouds and sky. Rubens' power of expressing motion perhaps arose from the facility of his pencil, and his habitually trusting a good deal to memory and imagination in his compositions; for this quality can be given in no other way. It is to be regretted that he so seldom painted portraits, as those he executed (and in the gallery at Munich there are some fine specimens) possess very high qualities. His landscapes are often delightful, being generally truthful representations of Flemish scenery.

It remains to speak of Vandyck and Rembrandt, the one the disciple of Rubens, the other the entire founder of his own school. It is not possible for two painters to be more opposite. The characteristic merits of the former are very happily summed up in a single line of a poetical critic, where he speaks of "The soft precision of the clear Vandyck."

The general object of this analysis of the works of the great masters has been to show that their pre-eminence has constantly depended, not on the creation of a fantastic, abstract excellence, existing nowhere but in their own minds, but in their selecting and embodying some one view of nature, which came immediately under their habitual observation, and which their particular genius led them to study and imitate with success. This is certainly the case with Vandyck. His portraits, mostly of English women, in the collection in the Louvre, have a cool refreshing air about them, a look of simplicity and modesty even in the very tone, which forms a fine contrast to the voluptuous glow and mellow golden lustre of Titian's Italian women. There is a quality of flesh-colour in Vandyck which is to be found in no other painter, and which exactly conveys the idea of the soft, smooth, sliding, continuous, delicately varied surface of the skin. The objects in his pictures have the least possible difference of light and shade, and are presented to the eye without passing through any indirect medium. It is this extreme purity and silvery clearness of tone, together with the facility and precision of his particular forms, and a certain air of fashionable elegance, characteristic of the age in which he flourished, that places Vandyck in the first rank of portrait painters.

Rembrandt is peculiarly distinguished by the extreme originality of his style. He may be said to have created a medium of his own, through which he saw all objects. He was the grossest and the least vulgar, that is to say, the least common-place in his grossness, of all men. He was the most downright, the least fastidious of the imitators of nature. He took any object, he cared not what, how mean soever in form, colour, and expression; and from the light and shade which he threw upon it, it came out gorgeous from his hands. As Vandyck made use of the smallest contrasts of light and shade, and painted as if in the open air, Rembrandt used the most violent and abrupt contrasts in this respect, and painted his objects as if in a dungeon. His pictures may be said to be "bright with excessive darkness." His vision had acquired a lynx-eyed sharpness from the artificial obscurity to which he had accustomed himself. "Mystery and silence hung upon his pencil." Yet he could pass rapidly from one extreme to another, and dip his colours with equal success in the gloom of night or in the blaze of the noon-day sun. In surrounding different objects with a medium of imagination, solemn or dazzling, he was a true poet; in all the rest he was a mere painter, but a painter of no common stamp. The powers of his hand were equal to those of his eye; and indeed he could not have attempted the subjects he did, without an execution as masterly as his knowledge was profound. His colours are sometimes dropped in lumps on the canvass; at other times they are laid on as smooth as glass; and he not unfrequently painted with the handle of his brush. He had an eye for all objects as far as he had seen them. His history and landscapes are equally fine in their way. His landscapes we could look at for ever, though there is nothing in them. But "they are of the earth, earthy." It seems as if he had dug them out of nature. Every thing is so true, so real, so full of all the feelings and associations which the eye can suggest to the other senses, that we immediately take as strong an affection to them as if they were our home—the very place where we were brought up. No length of time could add to the intensity of the impression they convey. Rembrandt is the least classical and the most romantic of all painters. His *Jacob's Ladder* is more like a dream than any other picture that ever was painted. The figure of Jacob himself is thrown in one corner of the picture like a bundle of clothes, while the angels hover above the darkness in the shape of airy wings.

It would be needless to prove that the generality of the Dutch painters copied from actual objects. They have become almost a bye-word for carrying this principle into its abuse, by copying every thing they saw, and having no choice or preference of one thing to another, unless that they preferred that which was most obvious and common. We forgive them. They perhaps did better in faithfully and skilfully imitating what they had seen, than in imagining what they had not seen. Their pictures at least show that there is nothing in nature, however mean or trivial, that has not its beauty, and some interest belonging to it, if truly represented. We prefer Vangoyen's views on the borders of a canal, the yellow-

Fine Arts.

tufted bank and passing sail, or Ruysdael's woods and sparkling water-falls, to the most classical or epic compositions which they could have invented out of nothing; and we think that Teniers' boors, old women, and children, are very superior to the little carved ivory Venuses in the pictures of Vanderneer; just as we think Hogarth's *Marriage à la Mode* is better than his *Sigismunda*, or, as Wilkie's *Card-Players* is better than his *Alfred*. We should not assuredly prefer a *Dutch Fair* by Teniers to a *Cartoon* by Raphael; but we suspect we should prefer a *Dutch Fair* by Teniers to a *Cartoon* by the same master; or we should prefer truth and nature in the simplest dress, to affectation and inanity in the most pompous disguise. Whatever is genuine in art must proceed from the impulse of nature and individual genius.

French and Spanish painters.

In the French school there are but two names of high and established reputation, N. Poussin and Claude Lorraine. Of the former we have already spoken; of the latter we shall give our opinion when we come to speak of our own Wilson. We ought not to pass over the names of Murillo and Velasquez, those admirable Spanish painters. It is difficult to characterize their peculiar excellences as distinct from those of the Italian and Dutch schools. They may be said to hold a middle rank between the painters of mind and body. They express not so much thought and sentiment, nor yet the mere exterior, as the life and spirit of the man. Murillo is probably at the head of that class of painters who have treated subjects of common life. After making the colours on the canvass feel and think, the next best thing is to make them breathe and live. But there is in Murillo's pictures of this kind a look of real life, a cordial flow of native animal spirits, which we find nowhere else. We might here refer particularly to his picture of the *Two Spanish Beggar Boys*, in the collection at Dulwich College, which cannot easily be forgotten by those who have ever seen it.

Progress of art in Britain.

We come now to treat of the progress of art in Britain. We shall speak first of Hogarth, both as he is the first name in the order of time that we have to boast of, and as he is the greatest comic painter of any age or country. His pictures are not imitations of still life, or mere transcripts of incidental scenes or customs; but powerful moral satires, exposing vice and folly in their most ludicrous points of view, and, with a profound insight into the weak sides of character and manners, in all their tendencies, combinations, and contrasts. There is not a single picture of his, containing a representation of merely natural or domestic scenery. His object is not so much "to hold the mirror up to nature," as "to show vice her own feature, scorn her own image." Folly is there seen at the height—the moon is at the full—it is the very error of the time. There is a perpetual collision of eccentricities, a tilt and tournament of absurdities, pampered into all sorts of affectation, airy, extravagant, and ostentatious! Yet he is as little a caricaturist as he is a painter of still life. Criticism has not done him justice, though public opinion has. His works have received a sanction which it would be vain to dispute, in the universal delight and admiration with which they have been regarded, from their first appearance to the present moment. If the quantity of amusement, or of matter for reflection, which they have afforded, is that by which we are to judge of precedence among the intellectual benefactors of mankind, there are perhaps few persons who can put in a stronger claim to our gratitude than Hogarth. The wonderful knowledge which he possessed of human life and manners is only to be surpassed (if it can be) by the powers of invention with which he has arranged his materials, and by the mastery of execution with which he has embodied and made tangible the very thoughts and passing movements of the mind. Some persons object to the style of Hogarth's pictures, or the class to which they belong. First, Hogarth belongs to no class, or, if he belongs to any, it is to the same class as Fielding, Smollett, Vanbrugh, and Molière. Besides, the merit of his pictures does not depend on the nature of his subjects, but on the knowledge displayed of them, on the number of ideas, on the fund of observation and amusement contained in them. Make what deductions you please for the vulgarity of the subjects—yet in the research, the profundity, the absolute truth and precision of the delineation of character,—in the invention of incident, in wit and humour, in life and motion, in everlasting variety and originality,—they never have been, and probably never will be, surpassed. They stimulate the faculties, as well as amuse them. "Other pictures we see, Hogarth's we read!"[1]

There is one error which has been frequently entertained on this subject, and which we wish to correct, namely, that Hogarth's genius was confined to the imitation of the coarse humours and broad farce of the lowest life. But he excelled quite as much in exhibiting the vices, the folly, and frivolity of the fashionable manners of his time. His fine ladies do not yield the palm of ridicule to his waiting-maids, and his lords and his porters are on a very respectable footing of equality. He is quite at home, either in St Giles's or St James's. There is no want, for example, in his *Marriage à la Mode*, or his *Taste in High Life*, of affectation verging into idiotcy, or of languid sensibility that might

Die of a rose in aromatic pain.

Many of Hogarth's characters would form admirable illustrations of Pope's Satires, who was contemporary with him. In short, Hogarth was a painter of real, not of low life. He was, as we have said, a satirist, and consequently his pencil did not dwell on the grand and beautiful, but it glanced with equal success at the absurdities and peculiarities of high or low life, "of the great vulgar and the small."

To this it must be added, that he was as great a master of passion as of humour. He succeeded in low tragedy as much as in low or genteel comedy, and had an absolute power in moving the affections and rending the hearts of the spectators, by depicting the effects of the most dreadful calamities of human life on common minds and common countenances. Of this the *Rake's Progress*, particularly the bedlam scene, and many others, are unanswerable proofs. Hogarth's merits as a mere artist are not confined to his prints. In general, indeed, this is the case. But when he chose to take pains, he could add the delicacies of execution and colouring in the highest degree to those of character and composition; as is evident in his series of pictures, all equally well painted, of the *Marriage à la Mode*.

We shall next speak of Wilson, whose pictures may be divided into three classes,—his Italian landscapes, or imitations of the manner of Claude,—his copies of English scenery,—and his historical compositions. The first of these are, in our opinion, by much the best; and we appeal, in support of this opinion, to the *Apollo and the Seasons*, and to the *Phaeton*. The figures are of course out of the question (these being as uncouth and slovenly as Claude's are insipid and finical); but the landscape in both pictures is delightful. In looking at them we breathe the air which the scene inspires, and feel the genius of the place present to us.

[1] See an admirable essay on the genius of Hogarth, by Charles Lamb, in a periodical work called *The Reflector*.

In general, Wilson's views of English scenery want almost everything that ought to recommend them. The subjects he has chosen are not well fitted for the landscape painter, and there is nothing in the execution to redeem them. Ill-shaped mountains, or great heaps of earth,—trees that grow against them without character or elegance—motionless waterfalls,—a want of relief, of transparency and distance, without the imposing grandeur of real magnitude (which it is scarcely within the province of art to give), are the chief features and defects of this class of his pictures.

His historical landscapes, his *Niobe, Celadon, and Amelia,* &c., do not, in our estimation, display either true taste or fine imagination, but are affected and violent exaggerations of clumsy common nature. They are made up mechanically of the same stock of materials,—an overhanging rock, bare shattered trees, black rolling clouds, and forked lightning. The figures in the most celebrated of these are not, like the children of Niobe, punished by the gods, but like a group of rustics crouching from a hail-storm. We agree with Sir Joshua Reynolds, that Wilson's mind was not, like N. Poussin's, sufficiently imbued with the knowledge of antiquity to transport the imagination 3000 years back, to give natural objects a sympathy with preternatural events, and to inform rocks, and trees, and mountains, with the presence of a God. To sum up his general character, we may observe, that, besides his excellence in aërial perspective, Wilson had great truth, harmony, and depth of local colouring. He had a fine feeling of the proportions and conduct of light and shade, and also an eye for graceful form, as far as regards the bold and varying outlines of indefinite objects, as may be seen in his foregrounds, &c., where the artist is not tied down to an imitation of characteristic and articulate forms. In his figures, trees, cattle, and in everything having a determinate and regular form, his pencil was not only deficient in accuracy of outline, but even in perspective and actual relief. His trees, in particular, frequently seem pasted on the canvas, like botanical specimens. In fine, we cannot subscribe to the opinion of those who assert that Wilson was superior to Claude as a man of genius; nor can we discern any other grounds for this opinion than what would lead to the general conclusion,—that the more slovenly the performance the finer the picture, and that that which is imperfect is superior to that which is perfect. It might be said, on the same principle, that the coarsest sign-painting is better than the reflection of a landscape in a mirror; and the objection that is sometimes made to the mere imitation of nature cannot be made to the landscapes of Claude, for in them the graces themselves have, with their own hands, assisted in selecting and disposing every object. Is the general effect in *his* pictures injured by the details? Is the truth inconsistent with the beauty of the imitation? Does the perpetual profusion of objects and scenery, all perfect in themselves, interfere with the simple grandeur and comprehensive magnificence of the whole? Does the precision with which a plant is marked in the foreground take away from the air-drawn distinctions of the blue glimmering horizon? Is there any want of that endless airy space, where the eye wanders at liberty under the open sky, explores distant objects, and returns back as from a delightful journey? There is no comparison between Claude and Wilson. Sir Joshua Reynolds used to say that there would be another Raphael before there would be another Claude. His landscapes have all that is exquisite and refined in art and nature. Everything is moulded into grace and harmony; and, at the touch of his pencil, shepherds with their flocks, temples and groves, and winding glades and scattered hamlets, rise up in never-ending succession, under the azure sky and the resplendent sun, while

> Universal Pan
> Knit with the graces, and the hours in dance,
> Leads on the eternal spring.——

Michael Angelo has left, in one of his sonnets, a fine apostrophe to the earliest poet of Italy:

> Fain would I, to be what our Dante was,
> Forego the happiest fortunes of mankind.

What landscape painter does not feel this of Claude.[1]

We have heard an anecdote connected with the reputation of Gainsborough's pictures, which rests on pretty good authority. Sir Joshua Reynolds, at one of the academy dinners, speaking of Gainsborough, said to a friend, "He is undoubtedly the best English landscape painter." "No," said Wilson, who overheard the conversation; "he is not the best landscape painter, but he is the best portrait painter in England." They were both wrong; but the story is creditable to the versatility of Gainsborough's talents.

Those of his portraits which we have seen are not in the first rank. They are, in a good measure, imitations of Vandyck, and have more an air of gentility than of nature. His landscapes are of two classes or periods, his early and his later pictures. The former are minute imitations of nature, or of painters who imitated nature, such as Ruysdael, &c., some of which have great truth and clearness. His later pictures are flimsy caricatures of Rubens, who himself carried inattention to the details to the utmost limit that it would bear. Many of Gainsborough's later landscapes may be compared to bad water-colour drawings, washed in by mechanical movements of the hand, without any communication with the eye. The truth seems to be, that Gainsborough found there was something wanting in his *early manner*, that is, something beyond the literal imitation of the details of natural objects; and he appears to have concluded rather hastily, that the way to arrive at that *something more* was to discard truth and nature altogether. His fame rests principally, at present, on his fancy pieces, cottage children, shepherd boys, &c. These have often great truth, great sweetness, and the subjects are often chosen with great felicity. We too often find, however, even in his happiest efforts, a consciousness in the turn of the limbs, and a pensive languor in the expression, which is not taken from nature. We think the gloss of art is never so ill bestowed as on such subjects, the essence of which is simplicity. It is, perhaps, the general fault of Gainsborough, that he presents us with an ideal common life, of which we have had a surfeit in poetry and romance. His subjects are softened and sentimentalized too much; it is not simple unaffected nature that we see, but nature sitting for her picture.

Our artist, we suspect, led the way to that masquerade style, which piques itself on giving the air of an Adonis to the driver of a hay cart, and models the features of a milkmaid on the principles of the antique. His *Woodman's Head* is admirable. Nor can too much praise be given to his *Shepherd Boy in a Storm*, in which the unconscious simplicity of the boy's expression, looking up with his hands folded and with timid wonder,—the noisy chattering of a magpie perched above,—and the rustling of the coming storm in the branches of the trees,—produce a most delightful and romantic impression on the mind.

Gainsborough was to be considered, perhaps, rather as a man of delicate taste, and of an elegant and feeling mind, than as a man of genius; as a lover of the art rather than an artist. He devoted himself to it with a view to amuse and soothe his mind, with the ease of a gentleman, not with

[1] Claude left sketches of all the pictures he had painted, in a book which he denominated *Liber Veritatis.* By reference to this he avoided repetitions of his subjects; and it has served in aftertimes to ascertain the originality of his reputed productions. On the back of these drawings he wrote the names of the individuals by whom the pictures were purchased. That volume is now in the possession of the Duke of Devonshire.

the severity of a professional student. He wished to make his pictures, like himself, amiable; but a too constant desire to please almost unavoidably leads to affectation and effeminacy. He wanted that vigour of intellect which perceives the beauty of truth; and thought that painting was to be gained, like other mistresses, by flattery and smiles. It was an error which we are disposed to forgive in one around whose memory, both as an artist and a man, many fond recollections, many vain regrets, must always linger.[1]

The authority of Sir Joshua Reynolds, both from his example and instructions, has had, and still continues to have, a considerable influence on the state of art in this country. That influence has been, on the whole, unquestionably beneficial in itself, as well as highly creditable to the rare talents and elegant mind of Sir Joshua; for it has raised the art of painting from the lowest state of degradation,—of dry, meagre, lifeless inanity,—to something at least respectable, and bearing an affinity to the rough strength and bold spirit of the national character. Whether the same implicit deference to his authority, which has helped to advance the art thus far, may not, among other causes, limit and retard its future progress,—whether there are not certain original errors, both in his principles and practice, which, the farther they are proceeded in, the farther they will lead us from the truth,—whether there is not a systematic bias from the right line, by which alone we can arrive at the goal of the highest perfection,—are questions well worth considering.

We shall begin with Sir Joshua's merits as an artist. There is one error which we wish to correct at setting out, because we think it important. There is not a greater or more unaccountable mistake than the supposition that Sir Joshua Reynolds owed his success or excellence in his profession to his having been the first who introduced into this country more general principles of the art, and who raised portrait to the dignity of history, from the low drudgery of copying the peculiarities, meannesses, and details of individual nature, which was all that had been attempted by his immediate predecessors. This is so far from being true, that the very reverse is the fact. If Sir Joshua did not give these details and peculiarities so much as might be wished, those who went before him did not give them at all. Those pretended general principles of the art, which, it is said, "alone give value and dignity to it," had been pushed to their extremest absurdity before his time; and it was in getting rid of the mechanical systematic monotony and *middle forms*, by the help of which Lely, Kneller, Hudson, the French painters, and others, carried on their manufactories of history and face painting, and in returning (as far as he did return) to the truth and force of individual nature, that the secret both of his fame and fortune lay. The pedantic servile race of artists whom Reynolds superseded had carried the abstract principle of improving on nature to such a degree of refinement that they left it out altogether, and confounded all the varieties and irregularities of form, feature, character, expression, or attitude, in the same artificial mould of fancied grace and fashionable insipidity. The portraits of Kneller, for example, seem all to have been turned in a machine; the eye-brows are arched as if by a compass, the mouth curled, and the chin dimpled; the head turned on one side, and the hands placed in the same affected position. The portraits of this mannerist, therefore, are as like one another as the dresses which were then in fashion, and have the same "dignity and value" as the full-bottomed wigs which graced their originals. The superiority of Reynolds consisted in his being varied and natural, instead of being artificial and uniform. The spirit, grace, or dignity, which he added to his portraits, he borrowed from nature, and not from the ambiguous quackery of rules. His feeling of truth and nature was too strong to permit him to adopt the unmeaning style of Kneller and Hudson; but his logical acuteness was not such as to enable him to detect the verbal fallacies and speculative absurdities which he had learned from Richardson and Coypel; and from some defects in his own practice, he was led to confound negligence with grandeur. But of this hereafter.

Sir Joshua Reynolds owed his vast superiority over his contemporaries to incessant practice and habitual attention to nature, to quick organic sensibility, to considerable power of observation, and still greater taste in perceiving and availing himself of those excellencies of others which lay within his own walk of art. We can by no means look upon Sir Joshua as having a claim to the first rank of genius. He would hardly have been a great painter if other greater painters had not lived before him. He would not have given a first impulse to the art; nor did he advance any part of it beyond the point where he found it. He did not present any new view of nature, nor is he to be placed in the same class with those who did. Even in colour, his pallet was spread for him by the old masters; and his eye imbibed its full perception of depth and harmony of tone from the Dutch and Venetian schools rather than from nature. His early pictures are poor and flimsy. He indeed learned to see the finer qualities of nature through the works of art, which he, perhaps, might never have discovered in nature itself. He became rich by the accumulation of borrowed wealth; and his genius was the offspring of taste. He combined and applied the materials of others to his own purpose with admirable success; he was an industrious compiler or skilful translator, not an original inventor, in art. The art would remain, in all its essential elements, just where it is if Sir Joshua had never lived. He has supplied the industry of future plagiarists with no new materials. But it has been well observed, that the value of every work of art, as well as the genius of the artist, depends not more on the degree of excellence than on the degree of originality displayed in it. Sir Joshua, however, was perhaps the most original imitator that ever appeared in the world; and the reason of this, in a great measure, was, that he was compelled to combine what he saw in art with what he saw in nature, which was constantly before him. The portrait painter is, in this respect, much less liable than the historical painter to deviate into the extremes of manner and affectation; for he cannot discard nature altogether under the excuse that *she only puts him out*. He must meet her face to face; and if he is not incorrigible, he will see something there that cannot fail to be of service to him. Another circumstance which must have been favourable to Sir Joshua was, that though not the originator *in point of time*, he was the first Englishman who transplanted the higher excellencies of his profession into his own country, and had the merit, if not of an inventor, of a reformer of the art. His mode of painting had the graces of novelty in the age and country in which he lived; and he had, therefore, all the stimulus to exertion which arose from the enthusiastic applause of his contemporaries, and from a desire to expand and refine the taste of the public.

To an eye for colour, and for effects of light and shade, Sir Joshua united a strong perception of individual character—a lively feeling of the quaint and grotesque in expression, and great mastery of execution. He had comparatively little knowledge of drawing, either as it regarded proportion or form. The beauty of some of his female faces and figures arises almost entirely from their softness and fleshiness. His pencil wanted firmness and precision. The expression, even of his best portraits, seldom implies either lofty or impassioned intellect or delicate sensibility. He

[1] The idea of the necessity of improving upon nature, and giving what was called a *flattering likeness*, was universal in this country seventy years ago, so that Gainsborough is not to be so much blamed for tampering with his subjects.

also wanted grace, if grace requires simplicity. The mere negation of stiffness and formality is not grace; for looseness and distortion are not grace. His favourite attitudes are not easy and natural, but the affectation of ease and nature. They are violent deviations from a right line. Many of the figures in his fancy pieces are placed in postures in which they could not remain for an instant without extreme difficulty and awkwardness. We might instance the *Girl Drawing with a Pencil*, and some others. His portraits are his best pictures. He had a selection of fine subjects, and the great advantage, as far as practice went, in painting a number of persons of every rank and description. Some of the finest and most interesting are those of Dr Johnson, Goldsmith (which is, however, too much a mere sketch), Baretti, Dr Burney, John Hunter, and the inimitable portrait of Bishop Newton. The elegant simplicity of character, expression, and drawing, preserved throughout the last picture, even to the attitude and mode of handling, discover the true genius of a painter. We also remember to have seen a print of Thomas Warton, than which nothing could be more characteristic or more natural. These were all Reynolds' intimate acquaintances, and it could not be said of them that they were men of "no mark or likelihood." Their traits had probably sunk deep into the artist's mind; he painted them as pure studies from nature, copying the real image existing before him, with all its known characteristic peculiarities; and, with as much wisdom as good-nature, sacrificing the graces on the altar of friendship. They are downright portraits and nothing more, and they are valuable in proportion. In his portraits of women, Sir Joshua had to contend with, and often to modify—and this, probably, was one of the reasons of his generalizing so much—the barbarous costume of his time, yet he has done so with such success, and imparted so much grace and elegance to to his portraits of ladies, that an accomplished writer (Lady Eastlake) has lately attempted to prove by reference to his portraits that the costume of Sir Joshua's day is preferable to that of any other period.

The arch simplicity of expression, and the grotesque character which he has given to the heads of his children, though striking and beautiful, are borrowed from Correggio, and are rather overdone. His *Puck* is the most masterly of all these; and the colouring, execution, and character are alike exquisite. The single figure of the *Infant Hercules* is also admirable. Many of those to which his friends have suggested historical titles are mere common portraits or casual studies. Thus, the *Infant Samuel* is an innocent little child saying its prayers at the bed's feet: it has nothing to do with the story of the Hebrew prophet. The same objection will apply to many of his fancy pieces and historical compositions. There is often no connection between the picture and the subject but the name. Even his celebrated Iphigenia, beautiful as she is, and prodigal of her charms, does not answer to the idea of the story. In drawing the naked figure, Sir Joshua's want of truth and firmness of outline became more apparent; and his mode of laying on his colours, which in the face and extremities was relieved and broken by the abrupt inequalities of surface and variety of tints in each part, produced a degree of heaviness and opacity in the larger masses of flesh-colour, which can, indeed, only be avoided by extreme delicacy or extreme lightness of execution.

Shall we speak the truth at once? In our opinion, Sir Joshua did not possess either that high imagination, or those strong feelings, without which no painter can become a poet in his art. His larger historical compositions have been generally allowed to be most liable to objection in a critical point of view. We shall not attempt to judge them by scientific or technical rules, but make one or two observations on the character and feeling displayed in them. The highest subject which Sir Joshua has attempted was the *Count Ugolino*, and it was, as might be expected from the circumstances, a total failure. He had, it seems, painted a study of an old beggar-man's head; and some person, who must have known as little of painting as of poetry, persuaded the unsuspecting artist that it was the exact expression of Dante's Count Ugolino, one of the most grand, terrific, and appalling characters in modern fiction. Reynolds, who knew nothing of the matter but what he was told, took his good fortune for granted, and only extended his canvass to admit the rest of the figures. The attitude and expression of Count Ugolino himself are what the artist intended them to be, till they were pampered into something else by the officious vanity of friends—those of a common mendicant at the corner of a street, waiting patiently for some charitable donation. The imagination of the painter took refuge in a parish workhouse, instead of ascending the steps of the Tower of Famine. The hero of Dante is a lofty, high-minded, and unprincipled Italian nobleman, who had betrayed his country to the enemy, and who, as a punishment for this crime, is shut up with his four sons in the dungeon of the citadel, where he shortly finds the doors barred against him, and food withheld. He in vain watches with eager feverish eye the opening of the door at the accustomed hour, and his looks turn to stone; his children one by one drop down dead at his feet; he is seized with blindness, and, in the agony of his despair, he gropes on his knees after them,

> ....Calling each by name
> For three days after they were dead.

Even in the other world he is represented with the same fierce, dauntless, unrelenting character, "gnawing the skull of his adversary, his fell repast." The subject of the *Laocoon* is scarcely equal to that described by Dante. The horror *there* is physical and momentary; in the other, the imagination fills up the long, obscure, dreary void of despair, and joins its unutterable pangs to the loud cries of nature. What is there in the picture to convey the ghastly horrors of the scene, or the mighty energy of soul with which they are borne? His picture of *Macbeth* is full of wild and grotesque images; and the apparatus of the witches contains a very elaborate and well-arranged inventory of dreadful objects. His Cardinal Beaufort is a fine display of rich mellow colouring; and there is something gentlemanly and Shakspearian in the king and the attendant nobleman. At the same time we think the expression of the cardinal himself is too much one of physical horror, a canine gnashing of the teeth, like a man strangled. This is not the best style of history. Mrs Siddons as the *Tragic Muse* is neither the tragic muse nor Mrs Siddons; and we have still stronger objections to *Garrick between Tragedy and Comedy*.

In his historical works in particular there is a striking similarity between Sir Joshua Reynolds' theory and his practice; and as each of these has been appealed to in support of the other, it is necessary that we should examine both. Sir Joshua's practice was generally confined to the illustration of that part of his theory which relates to the more immediate imitation of nature; and it is to what he says on this subject that we shall chiefly direct our observations at present.

He lays it down as a general and invariable rule, that "*the great style in art, and the most* PERFECT IMITATION OF NATURE, *consists in avoiding the details and peculiarities of particular objects.*" This sweeping principle he applies almost indiscriminately to *portrait, history,* and *landscape;* and he appears to have been led to the conclusion itself, from supposing the imitation of particulars to be inconsistent with general rule and effect. It appears to us that the highest perfection of the art depends, not on separating, but on uniting general truth and effect with individual distinctness and accuracy.

First, It is said that the great style in painting, as it relates to the immediate imitation of external nature, consists in avoiding the details of particular objects. It consists

neither in giving nor avoiding them, but in something quite different from both. Any one may avoid the details. So far there is no difference between the *Cartoons* and a common sign painting. Greatness consists in giving the larger masses and proportions with truth;—this does not prevent giving the smaller ones too. The utmost grandeur of outline, and the broadest masses of light and shade, are perfectly compatible with the utmost minuteness and delicacy of detail, as may be seen in nature. It is not, indeed, common to see both qualities combined in the imitations of nature, any more than the combination of other excellences; nor are we here saying to which the principal attention of the artist should be directed; but we deny that, considered in themselves, the absence of the one quality is necessary or sufficient to the production of the other.

If, for example, the form of the eye-brow is correctly given, it will be perfectly indifferent to the truth or grandeur of the design, whether it consists of one broad mark, or is composed of a number of hair-lines arranged in the same order. So, if the lights and shades are disposed in fine and large masses, the *breadth* of the picture, as it is called, cannot possibly be affected by the filling up of those masses with the details, that is, with the subordinate distinctions which appear in nature. The anatomical details in Michael Angelo, the ever-varying outline of Raphael, the perfect execution of the Greek statues, do not destroy their symmetry or dignity of form; and in the finest specimens of the composition of colour we may observe the largest masses combined with the greatest variety in the parts of which those masses are composed.

The *gross* style consists in giving no details, the *finical* in giving nothing else. Nature contains both large and small parts, both masses and details; and the same may be said of the most perfect works of art. The union of both kinds of excellence, of strength with delicacy, as far as the limits of human capacity and the shortness of human life would permit, is that which has established the reputation of the most successful imitators of nature. Farther, their most finished works are their best. The predominance, indeed, of either excellence in the best masters has varied according to their opinion of the relative value of these qualities,—the labour they had the time or the patience to bestow on their works,—the skill of the artist,—or the nature and extent of his subject. But if the rule here objected to, that the careful imitation of the parts injures the effect of the whole, be once admitted, slovenliness would become another name for genius, and the most unfinished performance be the best. That such has been the confused impression left on the mind by the perusal of Sir Joshua Reynolds' *Discourses*, is evident from the practice as well as conversation of many (even eminent) artists. The late Mr Opie proceeded entirely on this principle. He left many admirable studies of portraits, particularly in what relates to the disposition and effect of light and shade; but he never finished any of the parts, thinking them beneath the attention of a great artist. He went over the whole head the second day as he had done the first, and therefore made no progress. The picture at last, having neither the lightness of a sketch nor the accuracy of a finished work, looked coarse, laboured, and heavy. Titian is an excellent example of high finishing united with breadth. In him the details are engrafted on the most profound knowledge of effect, and attention to the character of what he represented. His pictures have the exact look of nature, the very tone and texture of flesh. The variety of his tints is blended into the greatest simplicity. There is a proper degree both of solidity and transparency. All the parts hang together; every stroke tells, and adds to the effect of the rest. Sir Joshua seems to deny that Titian finished much, and says that he produced, by two or three strokes of his pencil, effects which the most laborious copyist would in vain attempt to equal. It is true, he availed himself in some degree of what is called *execution*, to facilitate his imitation of the details and peculiarities of nature; but it was to facilitate, not to supersede it. There can be nothing more distinct than execution and daubing. Titian, however, made a very moderate, though a very admirable, use of this power; and those who copy his pictures will find that the simplicity is in the results, not in the details. To conclude our observations on this head, we will only add, that while the artist thinks there is anything to be done, either to the whole or to the parts of his picture, which can give it still more the look of nature, if he is willing to proceed, we would not advise him to desist. This rule is the more necessary to the young student, for he will be apt to relax in his attention as he grows older.

Secondly, With regard to the imitation of expression, we can hardly agree with Sir Joshua, that "the perfection of portrait painting consists in giving the general idea or character without the individual peculiarities." No doubt, if we were to choose between the general character and the peculiarities of feature, we ought to prefer the former. But they are so far from being incompatible with, that they are not without some difficulty distinguishable from, each other. There is a general look of the face, a predominant expression arising from the correspondence and connection of the different parts, which it is of the first and last importance to give, and without which no elaboration of detached parts, or marking of the peculiarities of single features, is worth anything; but which, at the same time, is not destroyed, but assisted, by the careful finishing, and still more by giving the exact outline, of each part.

Till within these few years it was on this point that the modern French and English schools differed, and, in our opinion, were both wrong. The English seemed generally to suppose, that if they only left out the subordinate parts, they were sure of the general result. The French, on the contrary, as erroneously imagined that, by attending successively to each separate part, they would infallibly arrive at a correct whole; not considering that, besides the parts, there is their relation to each other, and the general expression stamped upon them by the character of the individual, which to be seen must be felt; for it is demonstrable, that all character and expression, to be adequately represented, must be perceived by the mind, and not by the eye only. The French painters gave only lines and precise differences, the English only general masses and strong effects. But sounder ideas and a more correct practice now prevail in both countries.

Much has been said of *historical portrait;* and we have no objection to this phrase, if properly understood. The giving historical truth to a portrait means, then, the representing the individual under one consistent, probable, and striking view; or showing the different features, muscles, &c., in one action, and modified by one principle. A portrait thus painted may be said to be *historical;* that is, it carries internal evidence of truth and propriety with it; and the number of individual peculiarities, as long as they are true to nature, cannot lessen, but must add to, the strength of the general impression.

It might be shown, if there were room in this place, that Sir Joshua has constructed his theory of the *ideal* in art upon the same mistaken principle of the negation or abstraction of *particular nature.* The *ideal* is not a negative, but a positive thing. The leaving out the details or peculiarities of an individual face does not make it one jot more ideal. To paint history, is to paint nature as answering to a general, predominant, or preconceived idea in the mind, of strength, beauty, action, passion, thought, &c.: but the way to do this is not to leave out the details, but to incorporate the general idea with the details; that is, to show the same expression actuating and modifying every movement of the muscles, and the same character preserved consistently through every part of the body. Grandeur does not consist in omitting the parts, but in connecting all the

parts into a whole, and in giving their combined and varied action: abstract truth or ideal perfection does not consist in rejecting the peculiarities of form, but in rejecting all those which are not consistent with the character intended to be given, and in following up the same *general idea* of softness, voluptuousness, strength, activity, or any combination of these, through every ramification of the frame. But these modifications of form or expression can only be learnt from nature, and therefore the perfection of art must always be sought in nature. The ideal properly applies as much to the *idea* of ugliness, weakness, folly, meanness, vice, as of beauty, strength, wisdom, magnanimity, or virtue. The antique heads of fauns and satyrs, of Pan or Silenus, are quite as ideal as those of the Apollo or Bacchus; and Hogarth adhered to an idea of humour in his faces, as Raphael did to an idea of sentiment. But Raphael found the character of sentiment in nature as much as Hogarth did that of humour, otherwise neither of them would have given one or the other with such perfect truth, purity, force, and keeping. Sir Joshua Reynolds' *ideal*, as consisting in a mere negation of individuality, bears just the same relation to real beauty or grandeur as caricature does to true comic character.

Writers on art have long been in the habit of complaining that the English are hitherto without any painter of serious historical subjects, who can be placed in the first rank of genius;—that although many of the pictures of modern artists have shown a capacity for correct and happy delineation of actual objects and domestic incidents, only inferior to the masterpieces of the Dutch School—and in landscape Turner and others have depicted the effects of air and of powerful relief in objects in a way which was never surpassed; yet in the highest walk of art—in giving the movements of the finer or loftier passions of the mind, this country has not produced a single painter who has made even a faint approach to the excellence of the great Italian painters;—and the pictures of Barry, Northcote, West, Fuseli, and Haydon have been instanced in proof of this assertion. But such complaints are most unjustly made: for how should works be expected of a class and quality for which there is neither demand, encouragement, sympathy, nor appreciation? Though it be undoubtedly true that the province of art as well as of literature is to lead and instruct the public mind, yet it is not less certain that both are acted on by, and reflect the feelings, tastes, and habits of, the people; and though for a long time various causes combined to check the progress of art in Britain, since the establishment of the English school its artists have not only energetically kept pace with, but often greatly aided in advancing, the spirit of the age.

When we consider the deplorable state of art when the English school was founded, we cannot admire too much the energy of the movement, and the success with which it was crowned. The eighteenth century was the period in history when art was most debased. All of art that remained to the world was the mannered and tawdry school of Louis XIV., then almost in a state of imbecility; and about the middle of the century when the English school was founded, there was no corresponding movement elsewhere, and bad taste had to be opposed in every direction. The modern French school dates from the end of last century, and at first it was anything but successful. A political bias inclined art to the same walk that literature had taken, namely, the classic, which emanated from the ancient republican states; and as sculpture is the chief expositor of that kind of art, painting was made entirely sculpturesque, and its powers and capabilities were confined within limits and forced in a direction at variance with its proper functions. Within the last thirty years, however, the French school has made great advances, and is now in a flourishing condition.

The modern school of Germany was not founded till the beginning of this century. It arose under most favourable circumstances; for peace had been established in Europe, and the nations required repose after a long and ruinous war, which, however, had dispersed the treasures of art in the various royal galleries, shown the public the value and importance attached to such works, and made their study more generally available. All these movements have combined to improve and elevate taste generally, and in this country in particular, abounding as it does in wealth and energy, they have been eagerly taken advantage of; so that the British school is rapidly attaining the high position that will fit it in every way to respond to the requirements of the greatest and wealthiest nation in the world.

It is now above a hundred years since Hogarth painted his *March to Finchley*. At that period art had fallen low indeed—the glorious schools of Italy and Germany had long passed away, as also had what is styled the revival in Bologna, an attempt that has in general been estimated too favourably, as it did more to injure art than to revive it—the lights of the Spanish, the Flemish, and the Dutch schools were extinguished, and all that remained was the baneful example of the French school of Louis XIV., and even it was in decadence. In Germany, French art as well as French literature alone prevailed, and in England a national school was scarcely hoped for. When Hogarth produced those wonderful works which so powerfully embody English character, he adopted, to a certain extent, in technical treatment, the style of Watteau, the painter, however, of whom France has most reason to boast as a genuine national artist. Thornhill was executing huge sprawling allegories in emulation of De la Fosse and other French painters, portrait painting was chiefly in the hands of foreigners, and landscape painting was almost unknown. Thus we find art everywhere paralyzed at the time when Hogarth and Reynolds arose to revive it—the productions of the former exceeding in humour every previous effort in art, the portraits of the latter ranking with those of Velasquez, Vandyck, and Rembrandt, while the works of their contemporaries, Wilson, Gainsborough, Bacon, &c., are deservedly held in high esteem. There is one striking peculiarity in the English school—it has not like others commenced timidly, risen to a certain point, and then fallen. No greater works have been produced in the English school than those of its founders Hogarth and Reynolds, in their peculiar walks. It has not, however, declined since the days of Reynolds; on the contrary, it has risen much higher. The explanation seems to be this, that the English school was the last that arose in Europe, having been instituted only in the middle of the eighteenth century, and the general revival of art over the greater part of Europe took place before there was any perceptible decadence in Britain. Though that revival therefore affected in the most striking manner the schools of France and Germany, where art was either in utter decay or had long passed away, and was therefore loudly called for and eagerly welcomed, the movement in England is to be viewed less in the light of a revival, than merely as aiding in bringing forth a rich harvest of increased motives and facilities of improvement, for the further sustenance and gradual development and increase of a healthy and vigorous system. Thus, for example, though we have not had a portrait painter superior to Reynolds, yet, admirable though that great painter's works are, increased knowledge has produced an appreciation of art that demands, and doubtless will soon call forth, a higher and purer style, uniting to the force of Reynolds more careful drawing, greater individuality of expression, and higher finish. And though Hogarth has never been excelled for broad humour, still the *Distraining for Rent—Reading the Will—The Penny Wedding*, and *The Chelsea Pensioners* of Wilkie, are higher works than any of Hogarth's, as they combine a greater number of the qualities essential to a complete work of art, and the expression is brought out with greater delicacy and

more artistic skill. The painters also of history and *genre* subjects of the present time go far beyond those who practised in the early period of the school. What works of that day would stand in comparison with those of Etty? In landscape the superiority is even more striking. Turner far surpassed Wilson and Gainsborough,—and Bonnington, Calcott, Collins, P. Nasmyth, Müller, and many others (we avoid names of living artists, and refer only to those lately deceased), may be successfully opposed to them; while our school of water-colour painters, which is of purely English origin, is looked up to and imitated all over Europe.

Besides the revival of art on the continent, a new influence has been brought to bear on British art, by the introduction of an element till lately unknown in this country, namely, government patronage. It was often made a subject of complaint, that while the governments of France and Germany gave liberal encouragement to the arts, the government of our country was noted for neglecting them. But the decoration of the new houses of parliament was at length taken advantage of as affording a fitting opportunity for employing native artists on national works; and about ten years ago competitions were instituted, and prizes offered, both in money and commissions for pictures. The amount of talent called forth in this way far exceeded expectation; and accordingly, several important commissions were awarded for pictures in fresco and in oil, though chiefly in the former style, as a species of painting not hitherto practised in England, and from its being thought best adapted for combining with architectural decoration. Several sculptors, too, —and the English school reckons at present many eminent names in that high walk of art—were employed by government. These commissions, so far as executed, satisfactorily demonstrate the high capabilities of the artists employed; but it is doubtful whether a demand for large works, especially when executed on walls, will become general in this country. There seem many reasons against it: the domestic habits of the people lead them to seek for enjoyment in their private dwellings, and there to collect around them what they prize most; works of large dimensions, therefore, can seldom be accommodated. Besides, largeness of style is in no degree dependent on dimensions of canvas; in a mercantile community too, large sums are seldom laid out without a calculation that it may be necessary at some future time to convert into money the property on which the expenditure was made, and moderately-sized pictures are generally preferred as an investment; and, indeed, extensive mansions adorned with fresco paintings are not now considered, as they were in former times, the means of adding importance to and handing down a family to posterity. Even in Germany, although art was there first fostered by government patronage, artists are turning their attention to private sales as the most lasting source from which art is to be supported. The King of Bavaria built churches principally with the view of encouraging fresco painting, but these have now become so numerous that there is scarcely a pretext for erecting one more; and his palaces, rebuilt or extended for the same purpose, are larger than he can occupy. In France a like feeling is gradually arising, and it has lately been strengthened by the following occurrence. The exiled Duchess of Orleans, in spring of the present year (1853), brought to public sale the gallery of modern French paintings which had been formed by the late duke, and a larger sum was realized than had been expended on the collection. In place of purchasing or commissioning easel pictures, had the duke employed the different artists to execute frescoes in some of his chateaux, they would never have formed a resource for his family in adversity, nor in any way benefited himself or others, as they would probably have been obliterated to make way for compositions illustrative of the deeds of the new dynasty.

Government has also taken up strenuously a plan which, it is strongly hoped, will improve the taste of the people, that, namely, of art tuition in design, particularly with reference to manufactures. With this view a number of schools have been instituted in London, in Edinburgh, and in the principal cities of the kingdom. These have been in operation for several years, most of them having been founded at the same time that government proposed competitions at Westminster Hall with the view of encouraging the fine arts. This latter plan seems, however, to have been discontinued, at least it is being but feebly carried out, while the schools of design are receiving the particular attention of government. On this legislative procedure, public opinion is much divided, many holding that, in place of forming schools where an inferior kind of art is taught, government should encourage only the highest, as that would involve improvement in all the inferior branches; others again—and among these many of the principal manufacturers—think that such schools now attempt too much, the plan having lately been tried, of communicating a practical knowledge of the particular trade or manufacture for which the designs are made. They hold that the education imparted should be limited to drawing and modelling, it being left to the employers and the master-designers in their establishments, to instruct the pupils in the kind of design that can be practically applied to the particular trade they engage in; as the attempt by these schools to turn out practical designers perfected in their profession is hopeless; and the little practical knowledge they can learn at the schools, serving only to puzzle them, must be all unlearned in the manufactory. There can be no doubt, however, that every step taken in disseminating education should be hailed with satisfaction,—that drawing, the medium by which knowledge is directly communicated to the mind through the eye, should be made a part of education as well as letters, and that galleries of art should be acquired by the nation, and be made available to the people in the same way as public libraries are. For it is in vain to educate men to execute fine designs, unless the people who are to purchase those designs are also sufficiently educated to be able to appreciate them.

Much has been written on the subject of artists forming themselves into societies or academies, and it has been alleged that all such institutions are injurious to art. This is surely very unreasonable. Artists are equally entitled to form societies for their mutual benefit and for advancing their profession generally, as members of the legal or medical profession. And if such combinations were injurious to art, it is reasonable to suppose that the artists themselves would be the first to make the discovery, seeing that whatever is detrimental to art must be hurtful to them; and it is surely natural that they should take a deep interest in art-education, and desire that a flourishing school of artists should succeed them, to maintain worthily and to perpetuate that profession to which all their energies have been devoted. The occasional outcry made against government assistance to academies is no good indication of a love of art. The support of that kind that this country has hitherto afforded to academies of art is of the most limited description, and immeasurably disproportionate to the sums expended in the endowment in universities of chairs in the various branches of literature and science, besides the numerous annual grants to learned bodies.

Art in France is perhaps, at present, in a more healthy state than it has been in any former period; for though entitled to claim, on the ground of birth, many eminent artists who flourished in past ages, the only really national French school was that of Louis Quatorze, which sprung up in an age when the standard of taste was extremely low. This school, when almost exhausted, was swept away at the Revolution; and the hard and exaggerated imitations of classic art then substituted, have not only been now much modified, but many of the artists of the French school have en-

tered on several other walks of art, in which they have displayed great talent. We shall enumerate some of the chief French artists of the present day, and note generally their distinguishing styles.

Horace Vernet is celebrated for his pictures of the various battles in which the French have been engaged. These are mostly executed on a large scale, and are remarkable for truth and power. He has also painted a variety of subjects from sacred history, treated in a very original manner, by assuming that the Arabian costume has undergone little change since the time of the patriarchs, whom accordingly he has dressed like Arabs; and by introducing in his backgrounds truthful delineations of Eastern scenery. The novelty of this style, and the forcible manner in which Vernet has carried it out, has made it popular in France. Many able artists have adopted it, and it is as much the characteristic of the French school now, as the classic was at the commencement of this century.

The classic school founded by David, but much modified and improved, is at present represented by Ingres, and his works are highly estimated in France.

Delaroche holds, perhaps, as high a position as any French artist; his subjects are historical, and range from the medieval period to modern times; his works are characterized by good drawing, carefully studied expression, and correct costume and accessories. He is one of the chief artists of what is styled the romantic, in contradistinction to the classic school, of which, as before stated, Ingres is now the leader.

Airy Scheffer also belongs to the romantic school, his subjects are almost entirely medieval, and his style partakes of German feeling to a greater extent than that of any other French artist.

Delacroix belongs to a department of the romantic school in which the attempt to introduce into it something of the rich colouring of the Venetian school has been made with much success. This fascinating style of art was introduced into France by the English artist Bonnington.

The *genre* subjects of Meissonier, which are of small dimensions and exquisitely finished, are highly valued.

Did our space permit, we could, in addition, enumerate many men of high ability, whose works, while they never fail to prove that our neighbours possess great readiness and facility in drawing, often display an amount of talent and originality highly creditable to French art.

The modern school of Germany deservedly holds a high rank, and in purity and elevation of style is superior to that of France. It is not older than the present century; and though in former ages there was a celebrated German school, of which there are many admirable examples extant, and it might be supposed that there would be a national bias in favour of this ancient school, still it can scarcely be called a revival of German art, as the founders of the modern school seem to have modelled their style not so much on old German as on early Italian art. They probably wished to adopt the purest model, and imagining that Italian art best afforded this, they resolved to be guided chiefly by its light. Many of the most distinguished German artists have sprung from the school of Dusseldorf. In this city there was at one time a celebrated gallery of pictures consisting chiefly of the *chef d'œuvres* of Rubens; but it so happened that one consequence of the various state partitions in Napoleon's time, was the transference of the Dusseldorf gallery to Munich the capital of Bavaria. But this spoliation, which at the time was looked upon by the Dusseldorfers as a heavy blow to their city, was the most fortunate thing for it that could have happened. German patriotism and talent more than made up for the loss, and the modern school that was founded in place of the Rubens gallery has produced a band of artists whose talents have made Dusseldorf celebrated all over Europe. German art owes much to state patronage; all the most eminent artists have been employed on important works by the kings of Bavaria, Prussia, and Saxony, and other German princes. Though the German artists adopted Italian art as the basis of their style, yet different artists chose the art of different epochs as their examples. Overbeck, whose pencil is chiefly devoted to religious subjects, studied the works of Fra Angelico, a painter who flourished about a century before Raphael, and whose style is distinguished by deep feeling and simplicity; while Cornelius, whose range is more extensive, embracing both classical and religious subjects, has been influenced by the works of M. Angelo, and the art of the cinquecento period. Kaulbach is more German in feeling: his *Battle of the Huns* and the *Taking of Jerusalem* are grand compositions. The frescoes executed by Bendeman at Dresden; by Cornelius, Schnor, and Hess at Munich; by Viet at Frankfort; by Stienle at Cologne; and at Dusseldorf, Elberfeld, Rheinstein, &c., by Sättegast, Müche, Deger, and others; and the easel pictures of Schadow, Müller, Rethel, Hildebrandt, Sohn, Lessing, Köhler, Riedel, one of the best colourists of the German school, Achenbach, Calame, and Schermer, landscape painters, and many others, have raised modern German art to a very high position, higher, indeed, in the opinion of many, than that of any other country at present.

Of course this pre-eminence is not generally admitted either by the artists of France or England. Many, however, of the most celebrated French artists (Airy Scheffer, for example) have evidently profited by studying German art; and there can be no doubt that good examples of art are more generally diffused among the people in Germany than in England or France. Even in their story and song books, although for the sake of cheapness the illustrations are roughly executed on wood, and printed on coarse paper, the drawing and composition evince the highest artistic feeling. In this country, again, we have cheap publications for the people, excelling those of every other nation in the literary department, and, in so far as paper, printing, and the mechanical skill of the wood-cutting are involved, far superior to the German publications. But the designs have not their purity of drawing and artistic feeling; and the dashing cleverness of execution in the English woodcuts, is rather to be blamed than praised, as indicative of a rashness and presumption requiring to be checked and kept in proper bounds by judgment formed on cultivated taste. The position of engraving, too, affords a fair criterion of the state of taste, and that is admitted to be higher in Germany at present than anywhere else. Line engraving, which alone can express the true feeling of good art, has some able professors in France, but in this country the aid of machinery, by which manual labour is saved, and a straining at effect, and what by engravers is called colour, has lowered the art, and line has been almost superseded by the inferior styles of mezzotinto and stipple engraving.

But let us refrain from farther comparisons; those we have indicated being made solely with the view of still farther exciting honourable emulation; and this, there can be no doubt, has been lately aroused by the great facilities of intercourse among nations, and the national exhibitions. The purity of design of the German school, and the variety and dexterity displayed in that of France, are qualities now generally admitted by the artists of this country, and anxiously noted with feelings of respect, and not slightingly as in former times; while the Germans and French, by their efforts, prove daily that they admire, and are anxious to infuse into their works, the brilliant colouring and truth to nature which have long been characteristics of the British school. (W. H—Z—T.) (W. B. J.)

Arts, *Degrees in*. See Universities.

ARUNDEL, a borough and market town in the county of Sussex, 57 miles from London. It is situated on the declivity of a hill, on the north bank of the river Arun, which is navigable for vessels of 200 tons, and consists of two principal streets, containing several houses of a superior class. Adjoining to it is the magnificent castle of the dukes of Norfolk. The municipal government is vested in a mayor, four aldermen, and twelve councillors. It returns one member to parliament. Its chief trade is in corn and timber. Pop. in 1851, 2748.

Arundel, *Thomas*, archbishop of Canterbury, born in 1353, was the second son of Robert, Earl of Arundel and Warren. At 22 years of age he was raised to the bishopric of Ely, to the church and palace of which he was a great benefactor. In 1386 he was appointed lord chancellor of England; two years after he was translated to the see of York, and in 1396 was advanced to the primacy of Canterbury, when he resigned the chancellorship. This was the first instance of the translation of an archbishop of York to the see of Canterbury. Scarcely was he fixed in this see, when he had a contest with the university of Oxford about the right of visitation. The affair was referred to the king, Richard II., who determined it in favour of the archbishop. At his visitation in London, he revived an old constitution, by which the inhabitants of the respective parishes were obliged to pay to their rector one halfpenny in the pound out of the rent of their houses. In 1398, in the parliament held at London, the Commons, with the king's leave, impeached the archbishop, together with his brother Richard Earl of Arundel, and the Duke of Gloucester, of high treason. He was sentenced to be banished, and within forty days to depart the kingdom on pain of death. He retired, first to France, and then to the Court of Rome, where Pope Boniface IX. gave him a kind reception, and nominated him to the Scottish archbishopric of St Andrews. He was engaged in the plot to depose Richard, and place the Duke of Lancaster on the throne; and returning to England along with him, he was restored to his see on Henry's accession. Two years after, the Commons moved that the revenues of the church might be applied to the public service; but Arundel opposed the measure with such vigour that it was thrown aside. In the year 1408 his zeal for the suppression of heresy was directed against the followers of Wickliffe. The most eminent victim of his persecution was Sir John Oldcastle, Lord Cobham. He also procured a synodical constitution, which prohibited the translation of the Scriptures into the vulgar tongue. This prelate died at Canterbury on the 20th February 1413, of an inflammation in his throat, with which he was seized, as affirmed by the Lollards, while pronouncing sentence upon Lord Cobham.

ARUNDELIAN or Oxford Marbles. These interesting relics of antiquity, which include the famous Parian Chronicle, derive their name from Thomas Earl of Arundel, or from his grandson the Hon. Henry Howard, (afterwards Duke of Norfolk) who presented the collection to the University of Oxford in the year 1667. They were purchased for the first proprietor in 1624 by Mr William Petty, an able antiquary employed by the Earl of Arundel to collect marbles, books, statues, and other curiosities in Italy, Greece, and Asia Minor. On their arrival in London in the year 1627 they were placed in the gardens of Arundel House, the site of which is now occupied by Arundel, Norfolk, Surrey, and Howard Streets in the Strand.

The Parian Chronicle, or Marmor Chronicon, was, when found, a large oblong slab of Parian marble, on which was engraved in capital letters a chronological compendium of the principal events of Greece during a series of 1318 years, beginning with the reign of Cecrops, B.C. 1582, and ending with the archonship of Diognetus, B.C. 264. This marble originally measured three feet seven inches and two feet eleven inches on the two sides respectively, its breadth being two feet seven inches; but the chronicle of the last 90 years is lost, so that the part now remaining ends at the archonship of Diotimus, 354 years before the birth of Christ; and in this fragment the inscription is at present so much corroded and effaced that the sense must in some measure be supplied by conjecture.

Immediately on their arrival they excited the greatest curiosity, and were examined by some of the most eminent literary men of the period; among others by Sir Robert Cotton, Selden, Patrick Young, and Richard James. Selden, along with Patrick Young, or, as he styled himself in Latin, *Patricius Junius*, and Richard James, immediately commenced their operations by cleaning and examining the marble containing the Smyrnean and Magnesian league, and afterwards proceeded to the Marmor Chronicon. The following year Selden published a small volume in quarto, including about 39 inscriptions copied from the marbles.

In the turbulent reign of Charles I., and the subsequent usurpation, Arundel House was often deserted by the illustrious owners; and, in their absence, some of the marbles were defaced and broken, and others either stolen or used for the ordinary purposes of architecture. The chronological marble, in particular, was unfortunately broken and defaced. The upper part, containing 31 epochas, is said to have been worked up in repairing a chimney-piece or hearth in Arundel House.

Selden's work becoming very scarce, a new edition of the inscriptions, by Prideaux, was printed at Oxford in 1676. In 1732 Maittaire obliged the public with a more comprehensive view of the marbles than either of his predecessors. Lastly, Dr Chandler published, in 1763, a new and improved copy of the marbles; in which he corrected the mistakes of the former editors, and in some of the inscriptions, particularly that of the Parian chronicle, supplied the *lacunæ* by many ingenious conjectures.

The Arundelian marbles, though generally regarded as genuine relics of antiquity, were, however, discovered in some instances to differ somewhat from the most authentic historical accounts. Sir Isaac Newton and several other eminent philosophers paid little or no regard to them; and their absolute authenticity has been severely questioned in an express dissertation upon the subject by the Rev. J. Robertson, published in 1788, entitled *The Parian Chronicle*. In this dissertation much ingenuity as well as learning is displayed, and the arguments are doubtless possessed of considerable force and plausibility; but Mr Robertson's dissertation has been ably answered, and the authenticity of the Parian chronicle vindicated, by several writers; particularly the late Professor Porson, in an examination of Mr Robertson's Dissertation, in the *Monthly Review* for January 1789. See also Hewlett's *Vindication*, and the *Archæologia*, vol. ix.

ARUSPICES, or Haruspices, in *Roman Antiquity*, an order of priests who pretended to foretell future events by inspecting the entrails of victims killed in sacrifice; and who were consulted on occasion of portents and prodigies. The aruspices were chosen from the best families; yet although their employment was of the same nature as that of the augurs, and they were much honoured, they never acquired the same political importance, being regarded rather as mere interpreters of the will of the gods, than as possessing any religious authority. Their college, as well as those of the other religious orders, had its particular registers and records.

ARVA, a county of northern Hungary, containing above 101,000 inhabitants. Its surface = 797 square miles, with extensive forests, 5 market-towns, and 92 villages.

ARVALES Fratres, in *Roman Antiquity*, a college of twelve priests, instituted by Romulus, and chosen out of

the most noble families, he himself being one of that body. They assisted in the sacrifices of the Ambarvalia, offered to Ceres and Bacchus in May for the prosperity of the fruits of the earth, when they wore on their heads crowns made of ears of corn. The origin of this institution was said to have been as follows. Acca Laurentia, Romulus's nurse, was accustomed once a year to make a solemn sacrifice for a blessing on the fields, her twelve sons always assisting her in the solemnity. On the death of one of them, Romulus offered himself to supply his place, and gave this small society the name of *Arvales Fratres*. This order was in great repute at Rome: they held the dignity for life, and never lost it on account of imprisonment, banishment, or any other accident. See AMBARVALIA.

ARVE, a well-known river which rises in the Col de Balme, one of the Savoyan Alps, and passing through the valley of Chamouni, falls into the Rhone near Geneva, after a course of about 50 miles.

ARVIL SUPPER, a feast or entertainment made at funerals in the north part of England. Arvil bread is the bread delivered to the poor at funeral solemnities.

ARVIRAGUS, a British king in the time of the Emperor Domitian. He gained a complete victory over Claudius; but being soon after besieged in the city of Winchester, he made a treaty with the Romans, and married the emperor's daughter Genuissa. This monarch lived to a good old age: he confirmed the ancient laws, enacted new ones, and liberally rewarded persons of merit.

ARX, in all ancient cities, was a fortified eminence or rock, either within or close by the city itself. The arx at Rome was a part of the Capitoline Hill, the other part containing the Capitoline temple. In Greek towns the arx was called ἄκρα or ἀκρόπολις, and in several of them it bore a distinct name; whence at Thebes it was called the Cadmea, at Argos Larissa, at Corinth Acrocorinthus, and at Athens, sometimes Cecropia, or simply ἡ πόλις. The modern name citadel does not correspond with the term arx in every respect, the latter being always situated on an eminence. (L.S.)

ARX also denotes a consecrated place on the Palatine Mount, where the augurs publicly performed their office. Some suppose the arx to have been the augural temple, but Varro expressly distinguishes between the two.

ARX was particularly used for a public place in Rome, set apart for the operations of the augurs; and is the same as what is otherwise called *auguraculum* and *auguratorium*, and in the camp *augurale*. Out of this arx it was that the *feciales*, or heralds, gathered the herbs used in the ceremony of making leagues and treaties.

ARZEW (the ancient *Arsenaria*), a seaport town of Algiers, province of Oran, on a bay of the same name. Long. 0. 16. 58. W. Lat. 35. 51. 39. N. The modern town is ill-built and inconsiderable, but has many fine Roman remains, and vast cisterns of the ancient city. About 5 miles distant there are numerous salt-pits.

ARZILLA, a small fortified town of Marocco, province of Fez, with about 1000 inhabitants. The battery mounts about 20 guns.

AS, in *Antiquity*, a weight, consisting of 12 ounces, being the same with *libra*, or the Roman pound. The word is derived from the Greek ἄις, which, in the Doric dialect, is used for εἷς, *one*, q. d. an entire thing: or, according to others, from *æs*, because made of brass.

It was also the name of a Roman coin, which was of different weight and material in different ages of the commonwealth. Under Numa Pompilius, according to Eusebius, the Roman money was either of wood, leather, or shells. In the time of Tullus Hostilius it was of brass, and called *as libra*, *libella*, or *pondo*, because actually weighing a pound or 12 ounces. The first Punic war, 420 years later, having exhausted the treasury, the *as* was reduced to two ounces. In the second Punic war, it was again reduced to half its weight, viz., to one ounce. And lastly, by the Papirian law it was still further reduced to the diminutive weight of half an ounce; and it is generally thought that it continued the same during the commonwealth, and even to the reign of Vespasian. The *as*, therefore, was of four different weights in the commonwealth. Its original stamp was that of a sheep, ox, or sow; but from the time of the emperors it had on one side a Janus with two faces, and on the reverse the rostrum or prow of a ship.

As also denoted any integer or whole; whence the English word *ace*. Thus *as* signified the whole inheritance; whence *hæres ex asse*, the heir to the whole estate.

ASAHEL (*i. e. God's creature*) son of David's sister Zeruiah, and brother of Joab and Abishai. He was noted for his swiftness of foot; and after the battle at Gibeon he pursued and overtook Abner, who, with great reluctance, and to preserve his own life, slew him with a backthrust of his spear, B.C. 1055.

ASAPH (*i. e., assembler;* Sept. Ἀσάφ), a Levite, son of Barachias, eminent as a musician, and appointed by David to preside over the sacred choral services which he organized. The "sons of Asaph" are afterwards mentioned as choristers of the temple, and this office appears to have been made hereditary in his family (1 Chron. xxv. 1, 2). The titles of twelve of the Psalms (lxxiii. to lxxxiii.) bear his name.

ASAPH, *St*, a small episcopal city of North Wales, county of Flint, 20 miles west of Chester, and 208 north-west of London. It is agreeably situated on an eminence near the northern extremity of the fertile vale of Clwyd, between the rivers Elwy and Clwyd, not far from their confluence. The city is small, consisting principally of a single street. It has a cathedral, a church, four chapels, a free grammar-school, Bishop Barrow's almshouse for eight widows, a bank, and a bridge of five arches over the Elwy. Since the passing of the Reform Act, it is a contributory borough to Flint. Pop. of borough in 1851, 2041.

The see is very ancient, having been established in the middle of the sixth century by Kentigern, otherwise called St Mungo, bishop of Glasgow. Driven from the north by persecution, he sought refuge here, and was protected by Cadwallon, who aided him in building a church and founding a college or monastery in this place. Being recalled to his original charge, he nominated as his successor a pious scholar named Asa or Asaph, from whom both the church and town received their designation. Whether Kentigern assumed the title of bishop while here is not known, but there is evidence that Asaph certainly did, and that on his death in 596, he was interred in his own cathedral. The first edifice, which was of wood, was consumed by fire in 1282. A more substantial building was soon afterwards erected by Bishop Anian; and this was nearly destroyed during the wars of Owen Glyndwr. It was partially rebuilt by Bishop Redman about 1480, but the choir remained unfinished till about 1770, when it was completed by the dean and chapter. In the parliamentary wars the edifice was converted into a barrack, and sustained great injury.

The present cathedral is a neat plain cruciform structure, with a square tower 93 feet high rising from the intersection of the nave and transepts. Its length from east to west is 179 feet, its breadth at the transept 108 feet, and at the nave and side aisles 68 feet. The east end is lighted by a large window, an imitation of one at Tintern Abbey, filled with modern stained glass; and several other stained windows have been added at different times. Among its monuments are an altar-tomb supporting a recumbent figure in episcopal robes, in memory of Bishop Dafydd ap Owen, who died in 1502; a full-length figure, in white marble, of Dean Shipley; an altar-tomb recording the decease of

Bishop Luxmore in 1830; and a mural tablet in memory of the poetess Felicia Hemans, who, during a great portion of her life, resided in the vicinity.

The episcopal palace is a large modern structure a little to the west of the cathedral, overlooking the Elwy. The parochial church, dedicated to St Asaph and St Kentigern, is situated at the foot of the hill of which the cathedral occupies the summit. The rivers in the neighbourhood abound with fish, and are much resorted to by anglers. There are also some remarkable caverns and other places of interest in the vicinity.

Among the prelates of this diocese may be especially named Bishop William Morgan, an eminent linguist, and the principal translator of the Welsh Bible, printed in 1588; Dr Isaac Barrow, uncle and preceptor of the great mathematician of the same name; Dr William Beveridge, an eminent orientalist and critic, as well as a devout, zealous, and useful theologian; and Dr Samuel Horsley, celebrated as a scholar, mathematician, and theologian.

ASAR-ADDON, or ESAR-HADDON. See ASSYRIA.

ASAROTUM (from α, privative, and σαίρω, I sweep), an ancient kind of mosaic pavement composed of coloured pebbles. The most celebrated was that at Pergamus, executed by Sosus, which exhibited the appearance of an unswept floor after a banquet, whence the chamber was called ἀσαρωτὸς οἶκος. The central part represented several doves sitting on the edge of a *cantharus*, and the image of one in the act of drinking was reflected in the water. An imperfect copy of this central group was found at Tivoli in 1737, and another, in better preservation, was discovered at Naples in 1833.—See Plin. xxxvi. 25.

ASBESTOS. See AMIANTHUS, and MINERALOGY.

ASCALON, or ASKELON (now called Askulan), a chief city of one of the five states of the Philistines, situated on the coast of the Mediterranean between Gaza and Ashdod, 12 geographical miles north of the former, 10 south by west of the latter, and 37 W.S.W. from Jerusalem. Ascalon was assigned to the tribe of Judah, but was never for any length of time in the possession of the Israelites. It afterwards fell successively into the hands of the Greeks, the Romans, and the Arabs. At the period of the first crusade it, as well as Jerusalem, was in the possession of the Khalifs of Egypt. The crusaders having advanced to Jerusalem, a very formidable Egyptian army, composed of Arabs, Turks, and Africans, hastened to defend it. When this army arrived after the capture of the holy city, it halted in a plain near Ascalon, while the Egyptian fleet took up its position along the shore. On receiving intelligence of this, Godfrey of Bouillon, and Tancred, issued out of Jerusalem with all their available forces to attack the enemy. The Christian army was very inferior in numbers to that of the Egyptians, but their former success and the conviction that God was on their side rendered them invincible. The battle was fought on the 15th of August 1099, and the slaughter of the Egyptians is said to have amounted to a fourth part of their whole forces, which consisted of 400,000 men. In the account of this battle given by Tasso in his *Jerusalem Delivered*, the poet has freely used his license. This signal victory was not followed up as would have been expected by an attack upon Ascalon, so that that city remained in the possession of the Egyptians till 1157, when it was taken by Baldwin III. king of Jerusalem, after a siege of five months. When Saladin had defeated and almost annihilated the Christian army in the plains of Tiberias, in 1187, Ascalon offered but a feeble resistance to his victorious army, surrendering after a siege of four days. Saladin repaired and strengthened its fortifications; but alarmed at the capture of Saint Jean d'Acre by the Crusaders under Richard Cœur de Lion in 1191, he caused Ascalon to be dismantled. From this time Ascalon lost much of its importance, and at length in 1270 its fortifications were totally destroyed by the Sultan Bibars, who filled up its port with stones to prevent its again falling into the hands of the Christians. This sealed the ruin of Ascalon, of which little now remains but the walls and fragments of granite pillars. The situation is described as strong; the thick walls, flanked with towers, were built on the top of a ridge of rock that encircles the town, and terminates at each end in the sea, and the ground within sinks in the manner of an amphitheatre.

ASCANIUS, the son of Æneas and Creusa, succeeded his father in the kingdom of the Latins, and defeated Mezentius, king of the Tuscans, who had refused to conclude a peace with him. He migrated to Alba Longa, and here he was succeeded by his son Silvius. Some writers relate that Ascanius was also called Ilus or Iulus, whence the origin of the *gens Julia* at Rome, who regarded Ascanius or Iulus as their ancestor. Horace elegantly alludes to this in addressing Augustus:—

Micat inter omnes
Julium sidus, velut inter ignes
Luna minores. Carm. 1. i. 12.

ASCENDANT, in *Astrology*, denotes the horoscope, or the degree of the ecliptic which rises upon the horizon at the time of the birth of any one. This is supposed to have an influence on the person's life and fortune, by giving him a bent and propensity to one thing more than another. In the celestial theme this is also called the *first house*, the *angle of the East*, or *Oriental angle*, and the *significator of life*. Such a planet ruled in his *ascendant*, Jupiter was in his *ascendant*, &c. Hence the word is also used in a moral sense for a certain superiority which one man has over another from some unknown cause.

ASCENSION, a solitary island in the Atlantic Ocean, Lat. 7. 55. 56. S., and Long. 14. 23. 50. W.; about 7½ miles in length, and 6 in breadth, and within the immediate influence of the south-east trade-wind. The whole character of the island is volcanic, and its surface is broken into mountains, hills, and ravines. Towards the south-east, the Green Mountain, the highest in the island, rises 2870 feet above the level of the sea, while the plains or table-lands surrounding it vary in height from 1200 to 2000 feet. On the north side they sweep gradually down towards the shore; but, on the south, they terminate in bold and lofty precipices. Steep and rugged ravines intersect the plains, opening into small bays or coves on the shore, fenced with masses of compact and cellular lava; and all over the island are found the usual products of volcanic action. The chief productions of the island now are green vegetables. Ascension was formerly noted for the abundance of turtle and turtle eggs found on its shores. The coasts abound with a variety of fish of excellent quality. The native wild animals are guinea-fowl, goats, cats, rats, and land-crabs; but the goats have been almost exterminated to make way for sheep and cattle. The air is clear and elastic, and the climate remarkably salubrious. The island was discovered by the Portuguese on Ascension day 1501; but remained uninhabited till after the arrival of Napoleon at St Helena, when it was taken possession of by the British Government, and it now forms a permanent station. The garrison, with their retainers, reside in George Town, on the north-west coast, which is abundantly supplied with fresh water from a magnificent cistern capable of containing 1700 tons of water, supplied by means of iron pipes from springs in the Green Mountain, six miles distant. Population about 400, including the garrison. Ascension is found useful as a station and rendezvous for the vessels employed on the coasts of Africa and Brazil. A crevice in one of the rocks was long known as *the sailor's post-office*, because letters were deposited there to be taken up by the next ship passing in a contrary direction.

Ascension Day, a festival of the Christian church held ten days before Whitsuntide, in memory of our Saviour's ascension into heaven.

Ascension, *right* and *oblique*. See Astronomy.

ASCETERIUM (from ἀσκήτης, *one who exercises*), in ecclesiastical writers, is frequently used for a monastery, or place set apart for the exercise of virtue and religion. Originally it signified a place where the athletæ or gladiators performed their exercises. Plato, *Gorg.* 42.

ASCETIC (from ἀσκέω, *I exercise*), an appellation given to such persons as, in the primitive times, devoted themselves to the exercises of piety and virtue in a retired life, and particularly to prayer, abstinence, and mortification. Afterwards this title was bestowed upon the monks, especially upon such of them as lived in solitude.

ASCHAFFENBURG, a city of Bavaria, in the circle of Lower Franconia and Aschaffenburg. It is pleasantly situated on the right bank of the Maine, here crossed by a stone bridge, 23 miles E.S.E. of Frankfort. It is surrounded by walls on every side, but that towards the river is indifferently built, and the streets are mostly narrow and crooked. On a commanding eminence stands the palace of Johannisburg, a large square edifice with a tower at each angle, and magnificent gardens attached. It was founded by the elector of Mentz in 1606, and is at present the ordinary summer residence of the king of Bavaria. Aschaffenburg has seven churches, one of which is an old Gothic building with the tombs of its princes; a public library of 22,000 volumes; a picture-gallery, gymnasium, lyceum, and an ecclesiastical seminary. Its manufactures are woollens, soap, leather, and coloured paper; and it has a considerable trade in timber, wine, and tobacco. Lat. 49. 58. 28. N. Long. 9. 8. 50. E. Pop. 10,000.

The principality of Aschaffenburg, which derived its name from this city, comprehended an area of 336 geographical square miles. It originally formed part of the electorate of Mentz, and in 1803 was made over to the archchancellor, Archbishop Charles of Dalberg. In 1806 it was annexed to the grand duchy of Frankfort; and in 1814 was transferred to Bavaria in virtue of a treaty concluded on 19th June between that power and Austria. Conjointly with Lower Franconia it now forms a circle of the kingdom of Bavaria.

ASCHAM, Roger, a very distinguished scholar and writer, was born at Kirby Wiske, a village in Yorkshire, near Northallerton, about the year 1515. John Ascham, his father, was house-steward in the family of Scroop, and by his wife Margaret was connected with several respectable families. A short time before his death, Sir Anthony Wingfield having conceived a predilection for his third son Roger, took him into his family, and extended his bounty so far as to give him the advantage of a private education along with his own sons. Under a domestic tutor he made a rapid progress in classical learning, and early discovered a great partiality for reading. The superiority of genius and docility of temper which he constantly displayed induced his patron to send him to St John's College, Cambridge, in the year 1530.

The revival of Grecian and Roman literature at the period Ascham entered upon his studies was peculiarly favourable to the natural bent of his inclination. A desire of excelling uniformly influenced his conduct, and, adopting the maxim *Qui docet discit*, he began to teach boys the rudiments of the Greek language as soon as he was acquainted with the elementary parts himself. His plan was approved by Pember, and under the direction of this valued friend he soon became acquainted with the best Greek and Latin authors. But he took particular delight in reading Cicero and Cæsar, and upon them formed the elegance of his Latin style, which proved so honourable and so advantageous in the after part of his life.

Ascham took his degree of bachelor of arts in his 18th year, and was chosen fellow of the college about a month afterwards. The favourable disposition, however, which he manifested towards the reformed religion was no small obstacle in the way of his preferment. He was admitted master of arts in the year 1537, and about this period he began to act in the capacity of a tutor.

His reputation for Greek learning soon brought him many pupils; several of whom afterwards rose to considerable eminence. Of these one of the most distinguished was William Grindall, who obtained the station of master of languages to the Lady Elizabeth, upon the recommendation of Sir John Cheke. The reason why Ascham himself was not appointed to that honourable office is not known; but his partiality for the university seems, from a hint in one of his letters, to have been the cause. At that period there was no particular chair appropriated to the Greek language, but Ascham was appointed by the university to read lectures upon that language in the schools. A dispute arose in the university at that time about the pronunciation of the Greek language, in which Ascham first opposed the method observed by Sir John Cheke and Sir Thomas Smith; but, upon more mature deliberation, he adopted that method, which has ever since been practised in the English schools. Both on account of the beauty of his handwriting, and the purity and elegance of his Latin, he was employed to write the public letters of the university.

By the advice of his friend Pember, he turned his attention to the study of instrumental music, and thereby enlivened his leisure hours, and prepared his mind for renewed exertion. In his study he also amused himself with embellishing the pages of his manuscripts with beautiful draughts, and in the field he joined in the diversion of the bow and arrow. The learned Ascham did not deem his labour improperly bestowed in writing a book entitled *Toxophilus*, in an age when the proper use of the bow was of more importance than for mere amusement. This work was written in a more natural, easy, and truly English diction than had hitherto been in use; and it also abounds with many beautiful allusions and curious fragments of English history. Ascham candidly acknowledges, that being anxious to make the tour of Italy, which was then the great republic of letters, and particularly of Grecian literature, he wished, by dedicating his book to the king, to obtain a pension to enable him to make that tour. It reflects some credit on Henry VIII. that in the year 1544 he settled upon him an annual pension of L.10, which Dr Johnson estimates at the value of L.100. Upon the death of Henry this pension was renewed by Edward VI., to whom he was afterwards appointed Latin secretary. In the same year, also, Ascham obtained the appointment of orator to the university; an office which he retained with great reputation during the period he was connected with the university.

For some years he received an annual gratuity from Lee, archbishop of York, but to what amount is not recorded; and, in 1548, upon the death of his pupil Grindall, preceptor to the Lady Elizabeth, his pupils and writings had acquired him such celebrity, that he was appointed to direct the studies of that princess. He successfully acquitted himself in that honourable charge; but two years after, from some unknown cause of dissatisfaction, he returned to the university, having taken an abrupt leave of the princess. This part of his conduct did not greatly affect his favour with royalty; for in the same year he was recalled to court, and appointed secretary to Sir Richard Morisine, ambassador to the Emperor Charles V. On his way to London he paid a visit to Lady Jane Grey, whom he found in her chamber reading Plato's *Phædo*, in Greek, "and that," says he, "with as much delight as some gentlemen would read a merry tale in Boccace;" while the duke and duchess, and the rest of the household, were hunting in the park.

In the character of secretary to Sir Richard, besides aiding him in the management of his public affairs, he also conducted his private studies. During the mornings of four days in the week he read with him a portion of Herodotus or Demosthenes, and in the evenings some pages of Sophocles or Euripides: on the other mornings he wrote the letters of public business, and on the evenings he either wrote his own private letters or continued his diary and remarks. While Ascham was on his travels, he made a short excursion to Italy; but was much disgusted with the manners of the people, especially of the Venetians. After his return from that tour, he favoured the world with a curious tract, entitled *A Report and Discourse of the Affairs and State of Germany*, &c.

Upon the death of Edward VI. Morisine was recalled, and Ascham returned to the university. But the fortune of Ascham soon took a favourable turn, through the interest of Bishop Gardiner, who, although he knew him to be a Protestant, obtained for him the office of Latin secretary to the queen, with a salary of L.20 a year, and permission to retain his university emoluments. The prudence of Ascham enabled him to act a respectable part, both under the intolerant reign of Mary, and also in the most perilous situations during the reign of Elizabeth; and the readiness and elegance of his Latin style rendered him a useful member at court. He is reported to have written, during the course of three days, 47 letters to persons in the highest ranks of life.

When the crown passed to Elizabeth, it made little alteration in the condition of Ascham, who still retained his station. He spent several hours every day in reading the learned languages with the queen. Her proficiency was equal to his pains; and it might have been expected that his services would have received some reward more ample than L.20 per annum, together with the prebend of Westwang. The allegation that the queen kept him poor because he was extravagant and addicted to cock-fighting, is hardly satisfactory.

In consequence of a conversation which took place in the apartment of secretary Cecil, upon the subject of education, Sir Richard Sackville, who was present, requested Ascham to write a book on the general subject of education. This work is entitled *The Schoolmaster*, and contains many excellent instructions to the teachers of youth. It was published by his widow after his death. By too close application to composing a poem, which he intended to present to the queen on the New-year's day of 1569, he was seized with an illness which proved fatal. He died on the 23d of December 1568. His death was universally lamented, and the queen expressed her regret by saying, that "she would rather have lost L.10,000 than her tutor Ascham." His epistles, which are valuable both on account of their style and historical information, were published after his death, and dedicated to the queen: the best edition is that of Elstob, published at Oxford in 1703. His English works were published in 4to, with a life by Dr Johnson, in 1767. This edition has been reprinted in 8vo.

ASCHERSLEBEN, a circle in the government of Magdeburg and province of Saxony, in Prussia, formed out of a part of the principality of Halberstadt and the abbey of Quedlinburg. It contains 198 square miles, or 126,720 acres. Pop. in 1849, 49,816. The Bode and the Eine are the chief rivers; and on their banks the land is highly fertile, producing corn, flax, and rape-seed. Quedlinburg is the chief city of the circle.

ASCHERSLEBEN, a city in the circle of the same name, containing 1214 houses and 12,139 inhabitants. It has an extensive trade in friezes, flannels, and other woollen goods, and in linen, leather, tobacco, and rape-oil.

ASCII (α, priv. and σκία), an appellation given to those inhabitants of the earth who at certain seasons of the year have no shadow: such are all the inhabitants of the torrid zone when the sun is vertical to them.

ASCITÆ (from ἀσκός, *a bag* or *bottle*), a sect of the Montanists, who appeared in the second century. They were so called because they introduced a kind of Bacchanals into their assemblies, who danced round a skin or bag blown up, saying they were those new bottles filled with new wine whereof our Saviour makes mention, Matth. ix. 17.

ASCITES (from ἀσκός), an old name for peritoneal dropsy.

ASCLEPEIA, a festival of Æsculapius (Ἀσκλήπιος), the god of physic, observed particularly at Epidaurus every five years, where it was attended with a contest between the poets and musicians, whence it was likewise called Ἱερός Ἀγῶν, *the sacred contention*. It was celebrated on the eighth day of the month Elaphebolion (March).

ASCLEPIAD, in *Ancient Poetry*, a verse composed of four feet, the first a spondee, the second a choriambus, and the last two dactyls; or of four feet and a cæsura, the first a spondee, the second a dactyl and cæsura, then two dactyls; as, *Mæcenas atavis edite regibus.*

ASCLEPIADÆ, the descendants of Asclepius, or Æsculapius, by his sons Machaon and Podalirius, who were physicians in the Greek army, and ruled over Tricca, Ithome, and Œchalia. Combining the functions of priest, prophet, and physician, they spread themselves, along with the worship of the god, over Greece and Asia Minor. They may be regarded as the founders of scientific medicine. They resided in the temples of the god, and there wrought cures of the sick by various remedies, by charms, incantations, and also by means which are supposed to have reference to magnetism. The *Sermones Sacri* of the orator Aristides contain some curious accounts of these mysterious cures. This order undoubtedly had its origin in Egypt, whence the *coluber Æsculapii*, or sacred serpent, was brought by the Phœnicians to Epidaurus the chief seat of the god. Strangers, as Galen reports, were eventually initiated into the mysteries of this order. The priests were bound by a solemn oath not to divulge the secrets of their knowledge. Hippocrates, who was himself of the fraternity, has preserved the form of adjuration used on such occasions. The worship of Æsculapius was introduced at Rome in B.C. 293, for the purpose of averting a pestilence.

The name Asclepiades was borne by a great number of physicians, of whom the most famous was a native of Prusa in Bithynia, who was the founder of the methodical school, and practised at Rome about B.C. 50.

ASCLEPIODORUS, a famous Athenian painter cotemporary with Apelles. See *Index*.

ASCOLI (the *Asculum Picenum* of the Romans), an ancient episcopal city of Italy, States of the Church, and capital of a delegation of the same name. It is situated on the right bank of the river Tronto, at the junction of that river with the Castellano, 53 miles south of Ancona. It is a handsome and well-built town, with a cathedral and numerous churches, many of which are ornamented with valuable paintings by native artists. It has also a Jesuit's college, governor's residence, many private palaces, and a modern *palazzo* containing a museum, library, and theatre. It is surrounded by old walls and towers, and contains a citadel. Its harbour is defended by two forts, and is frequented by coasting vessels. Pop. 13,000.

ASCOLIA, a festival celebrated by the Athenian husbandmen in honour of Dionysus (Bacchus).

ASCOLIASMUS, an amusement with which the Athenians diverted themselves during the Anthesteria and other festivals of Bacchus, to whom they sacrificed a he-goat, because that creature is destructive to vines; and after inflating its skin and smearing it with oil, they attempted to dance upon

Asconius || Ashantee.

it, thereby occasioning much merriment among the spectators. Virgil alludes to this custom:

inter pocula læti,
Mollibus in pratis unctos saliêre per utres. Georg. ii. 384.

ASCONIUS, Q. PEDITANUS, a Roman of the time of Vespasian, who wrote a good commentary on the orations of Cicero, a fragment of which was recovered by Poggio Bracciolini, when he attended the Council of Constance in 1416; but the MS. has again disappeared. Other fragments have been recovered by Mai. The best edition of Asconius is that of Orelli, Zurich, 1833.

ASCRIPTICII, in *Roman Antiquity*. See ACCENSI.

ASCRIPTITII, or ADSCRIPTITII, a kind of serfs, so annexed to the lands that they may be transferred and sold with them. Adscriptitii is sometimes also used in speaking of aliens or foreigners newly admitted to the freedom of a city or country.

ASDRUBAL, the name of several Carthaginian generals. See CARTHAGE.

ASELLIO, GASPARO, a physician of Cremona, born in 1581, who was afterwards professor of anatomy at Pavia. He is best known by his important discovery of the *Lacteal Vessels*. His treatise (*De lactibus*, Milan, 4to), on this subject was posthumous; being published in 1627, a year after his death.

ASH-WEDNESDAY, the first day of Lent, supposed to have been so called from a custom in the church of sprinkling ashes on the heads of penitents then admitted to penance. The primitive church did not commence Lent until the following Sunday: the present commencement was instituted by Pope Felix III., A.D. 487.

ASHANTEE, a country in Western Africa, in the interior of the Gold Coast. The Ashantee empire, including the numerous districts at that time entirely reduced under its control and jurisdiction, was considered by M. Dupuis as extending from Lat. 5. 0. to 9. 0 N., and from Long. 0. to 4. 0. W., comprising a space of about 50,000 square miles, inhabited by 3,000,000 of people. The original Ashantee, however, is not supposed to include more than a third of this large territory.

History of the Ashantee empire.

Tradition represents the Ashantees as deriving their origin from numerous bands of emigrants, who, two or three centuries ago, were driven before the Moslem tribes migrating southward from the countries on the Niger and Senegal. The Ashantees having occupied and cleared a region before covered with almost impenetrable forests, defended themselves with a valour which became part of their national character, and which raised them from a band of fugitives to the rank of a powerful and conquering nation. They even subdued and reduced into vassalage several of the Moslem tribes by whom they had been formerly supplanted.

Early in the eighteenth century the Ashantees first came under the notice of Europeans, through the successful wars in which they engaged with the kingdoms bordering on the maritime territory. Sai Tooto may be considered as the real founder of the Ashantee power. He either built or greatly extended and embellished Coomassie, the capital; he subdued the neighbouring state of Denkera, and the Mahometan countries of Gaman and Banna, the latter of which has been called the right arm of Ashantee; and extended the empire by conquests both on the east and west. His successor made further acquisitions of territory towards the coast.

In 1800 the throne was mounted by Sai Tooto Quamina, who soon showed himself animated by a peculiar spirit of enterprise and ambition. He appears early to have formed a desire of opening a communication with white nations, and of improving his country by the introduction of their arts and knowledge. Occupied, however, by wars and insurrections, he could not for some time turn his views in that direction. About 1808, however, a dispute arose among the chiefs of Assin, which in spite of the king's efforts at conciliation ended in an open rupture. The insurgent forces were defeated with great slaughter, and the chiefs compelled to seek refuge among the Fantees, the ruling people on the coast. The king's overtures of accommodation being again slighted, he determined to make the rebels and their protectors feel the weight of his vengeance. The allies found themselves wholly unable to resist the torrent of invasion; the country was laid waste with fire and sword, and they were driven with dreadful slaughter towards the coast. At length the fugitives reached the town of Anamaboe, where there was then a British fort. The governor exhorted the Anamaboes to endeavour to make pacific arrangements with this powerful enemy, and offered his mediation; but the citizens, falsely confident in their own strength, resolved to abide the contest. The result was the complete destruction of the town, with great slaughter among the inhabitants. The attempts of the Ashantees, however, to storm the English fort were unsuccessful, though the skill of their fire reduced the garrison, originally amounting to 24, to the number of 8 men fit for service. A truce was concluded, and the king having refused to make any terms except with the chief governor of Cape Coast, Colonel Torranne, who filled that office, at once repaired to Anamaboe. He was received by the Ashantee monarch with great pomp, and the result of their interview was a treaty by which the whole territory of Fantee, including Cape Coast itself, the capital, was ceded by right of conquest to the Ashantee empire. The governor took a still more questionable mode of securing the favour of this great potentate, delivering up to his mercy the two chiefs with whom the war had originated. The one effected his escape; the other was put to death with cruel ignominy.

Negotiations and war with the English.

The British government, actuated by very enlightened views, felt a wish to cultivate the alliance of this monarch, and to open a direct communication with him. They thus hoped not only to secure his friendship and commerce with his territories, but to obtain extensive information respecting the interior of Africa. In 1817, Messrs James, Bowdich, and Hutchison, departed on a mission to Coomassie. On their arrival they were received with dignified politeness, and invited to a public audience in the market-place. After one or two harmonious interviews, the king introduced the subject of certain sums which the British were bound to pay to the native governments, for permission to hold fortified factories. These sums the Fantees, as the ruling people on the coast, had been accustomed to receive; but the king, as having conquered the whole Fantee territory, claimed them now as due to himself. Mr James, who had come unprovided with any instructions to meet this apparently legitimate claim, simply replied that he would refer for instructions to the government at Cape Coast Castle. The king, who conceived that they came, as he said, "to make peace and settle all palavers," on finding them wholly unprepared to enter on what he viewed as the main object of discussion, broke out into an uncontrollable rage; called them cheats and liars; then started from his seat, bit his beard, exclaiming, that had a negro brought such a message he would have cut off his head. On seeing matters come to this extremity, the two junior members of the mission, Messrs Bowdich and Hutchison, conceiving that Mr James, by blind and obstinate adherence to rule, was endangering the English interests, and perhaps even the safety of the mission, took the negotiation into their own hands. They conducted it in a manner altogether satisfactory to the king: a treaty was concluded, by which all his demands were satisfied; and, after a residence of several months, they returned to Cape Coast.

The government at home, though they demurred somewhat to the very irregular course pursued by Mr Bowdich and his companion, saw the wisdom of cultivating an inter-

Ashantee.

course with this powerful African court. They determined to station at his court a fixed resident, and nominated to that station M. Dupuis, who had long filled with credit the important post of British consul at Mogadore. The new consul arrived at Cape Coast in January 1819. By that time a complete and unfortunate change had taken place in the views of the British local government. They had been gained entirely over to the interest of the Fantees or coast natives, who were constantly on the spot, and possessed eloquence, talents, and address. An insurrection had arisen in the interior of the Ashantee monarchy, respecting which the most exaggerated rumours were spread and listened to with blind credulity. Insulting messages were sent to the king, who was also informed that the natives of Cape Coast were setting his authority at open defiance, and were forming a wall to defend the town. Under the views which he had formed, the governor, on various pretences, prevented M. Dupuis for some time from proceeding on his mission; but on the arrival of more than one ambassador from the king, demanding reparation for the wrong committed against him, it was thought prudent that he should proceed to the court of Ashantee.

M. Dupuis set out on the 9th February 1820, and on the 28th arrived at Coomassie. He seems to have proceeded very judiciously, and in a manner at once firm and courteous; and after several confidential meetings with the king, a treaty was drawn up, which adjusted satisfactorily all the differences between the two parties. The king dismissed M. Dupuis with many marks of esteem and kindness, sending along with him two natives of distinction, to proceed as ambassadors to England, with a present of two beautiful leopards.

On his return to Cape Coast, he was deeply disappointed to find that the governor altogether disowned the treaty, representing it as having betrayed British interests, and as having wantonly transferred to Ashantee the sovereignty of the Gold Coast. At the same time the Fantee party persuaded Sir George Collier to refuse transporting to Britain the ambassadors sent by the king of Ashantee; conduct which could not but be in the highest degree offensive to that monarch.

M. Dupuis returned to England to represent the particulars to the government; but an entire change meantime took place in the administration of the British affairs in Africa. The African Company were induced to resign the command hitherto held by them over the forts, which were taken entirely into the hands of the crown. The first step adopted in consequence, was to invest Sir Charles M'Carthy with the general government of all this range of coast. The new governor arrived early in 1822; but though he had communicated with M. Dupuis, who earnestly endeavoured to impress him with his own ideas of African politics, Sir Charles soon implicitly adopted the principles and policy of the Fantee natives. He placed the town in a posture of defence, and formed alliances with all the neighbouring tribes, who ranged themselves under his standard. The dreaded conqueror of the Gold Coast appears to have died during the summer of 1823, and it was hoped that the hostile attitude exhibited by the English would overawe his successor. He, however, was already busied in warlike preparations. At length a negro serjeant in the English service was seized in the great square of Anamaboe, on pretext of some injurious expressions respecting the king; and after being detained for six weeks, seemingly in expectation of some negotiation being opened for his release, was beheaded at Donqua. The king now declared open war, summoning all his vassal princes, and calling upon them "to arm against Britain, even to the fishes of the sea." Yet at this very time he made overtures through the Dutch government at Elmina, who had always prudently cultivated his alliance; but these were deemed unworthy of answer.

It behoved now the English to meet in the field the formidable enemy whom they had provoked, and taken no pains to appease. In their first encounter, a reconnoitering party under Captain Laing defeated a body of the enemy; but the rash confidence thereby engendered soon after received a dreadful blow by the utter rout of the British force of 1000 men, near the boundary stream of the Prah, by a native army of about 10,000 men. The ill-fated commander, Sir Charles M'Carthy, is supposed to have perished in the disastrous attempt to retreat. Only fifty men, including two officers, Major Ricketts and Lieutenant Erskine, returned to the castle. All the rest, among whom were the chief civil functionaries, paid the penalty of their rash counsels.

The Ashantee army now marched upon Cape Coast, laying waste the country with fire and sword. At that place, however, the detachments of Major Chisholm and Captain Laing had united with the wrecks of the main corps, and prepared for defence with the characteristic vigour and courage of English troops. The king, flushed with victory, made repeated and desperate assaults, but at last sustained a signal defeat, on the 7th August 1826. He was then obliged to purchase peace at the price of 6000 ounces of gold, and to send his son as a hostage to Cape Coast Castle. Since this event, the Ashantee power on the coast has become extinct, and its limits are now many miles distant from the sea.

Recent events.

By the treaty concluded at the end of the war, the river Prah was fixed as the boundary of the Ashantee kingdom, and all the tribes to the south of it were placed under the British protection. Till within a comparatively recent date, this treaty was duly respected by the kings of Ashantee. Towards the end of 1852, however, decided symptoms were evinced of a disposition on the part of the Ashantee monarch to interfere with the states which this treaty had absolved from his jurisdiction. Two Assin chiefs, Chibbu and Gabri, who had in the time of the war revolted from Ashantee and joined the Fantee alliance, were discovered to be intriguing with the king of Ashantee, who had paid them 400 ounces of gold as the price of their meditated treason. According to the plan concerted, the king was to make a visit to Donqua for the purpose of making "custom" for the late chief of Denkera (who had formerly been a vassal of Ashantee), the pretext for an armed aggression of the Assin territory. With this view he had crossed the Prah with a force of about 7000 men. These warlike movements naturally excited much uneasiness at Cape Coast Castle, and for a period of some months no effort was spared by the British authorities to bring matters to a pacific settlement, while an armed force was at the same time held in readiness to meet the aggressors. It is satisfactory to know by the last despatch of Governor Hill to the Colonial Secretary (dated April 26. 1853), that the negotiations had proved so far successful, that the Ashantees had retraced their steps across the Prah, giving considerable hopes that war is for the present averted. The two chiefs, who had been found guilty of treason, had before this been publicly beheaded on the 18th April 1853, after a regular trial by the allied chiefs and the captains of Assin.

Present state of Ashantee.

Ashantee proper, comprising about 14,000 square miles, and a million of inhabitants, presents a dense and almost impenetrable forest, the routes through which consist merely of narrow winding tracts, in which, though it is possible for a man to ride, or a palanquin to be carried, no waggon of any description could pass. The interior country round the towns, however, is cultivated with diligence, the fields being kept very clean, and yielding in abundance grain, yams, vegetables, and fruits. The territory yields also a considerable quantity of gold; and that precious metal is brought in still greater abundance from the regions farther to the north, particularly Gaman, where it occurs not merely in the usual form of gold dust, but in pretty large fragments, mingled in

pits with rock and gravel. It is even said that, but for a superstitious idea, which induces the natives to leave the largest deposits untouched, the produce might be much more ample. The Ashantees are skilful in several manufactures, particularly in the great African fabric of cotton, which they weave with a loom of simple and rude construction. Their pottery and works in gold are also skilful, though surpassed by those produced in the more southern countries.

The government of Ashantee forms a mixture of monarchy and military aristocracy; the lower orders being held in the most complete thraldom, and liable either to be put to death or sold into slavery at the will of the chiefs. The king carries on all the ordinary administration of the state; but in questions relating to peace or war he is bound to consult the council of the caboceers or captains, which M. Dupuis calls a senate. Each of these caboceers keeps a little court, where he gives audience, and makes a profuse display of barbaric pomp. Polygamy is indulged in to an enormous extent. The king has a regular allowance of 3333 wives; but in Africa these princesses are employed variously, as guards, messengers, and even in the humblest services. The crown, as often happens in barbarous countries, descends to the king's brother, or sister's son, not to his own offspring.

The Ashantee monarchs, though so extremely ambitious, appear to pay considerable regard to the faith of treaties, seeking always a plausible ground of war; and, even when justly provoked, not usually commencing it without previous overtures of negotiation. The barbarous and capricious governments, however, by which they are surrounded, jealous of the Ashantee power, without duly measuring their own strength, afford frequent cause of justifiable invasion.

The darkest feature in the Ashantee character is visible in the dreadful system of human sacrifice. It is founded on a wild idea of filial and relative piety, which makes the chiefs fancy it their duty to water with blood the graves of their ancestors, whose rank in the future world will, they imagine, be measured by the number of attendants thus sent along with them. There are two fixed annual periods called the great *Adai* and little *Adai*, at each of which human victims are immolated to a monstrous extent. Still more dreadful is the custom celebrated after the death of the king, or any member of the royal house. When Mr Bowdich was at Coomassie, the monarch, in honour of his mother, had sacrificed no less than 3000 victims. These are chiefly prisoners of war or condemned criminals. British influence, however, seems to have diminished this shocking practice.

ASHBOURNE, a market-town in the hundred of Wirksworth, and county of Derby, near the river Dove. It contains a large church of the thirteenth century. The manufactures are cotton, lace, iron, &c. A good corn-market is held here every Saturday. Pop. in 1851, 2418. Distance from London 139 miles.

ASHBURTON, a borough and market-town of England, in the hundred of Teignbridge and county of Devon, 192 miles W.S.W. of London, and 18 S.S.W. of Exeter. It stands in a valley surrounded on every side by hills, at a short distance from the river Dart, and consists principally of one long street on the high road between London and Plymouth. The church of St Andrew is a handsome Gothic structure, built in the form of a cross, with a tower ninety feet high. Ashburton has a bank, three chapels, a free grammar-school, with an exhibition and two scholarships at Exeter college, Oxford, and numerous charities. It is the seat of one of the stannary courts; and previous to the Reform Act, it returned two members to parliament, but now only one. Population in 1851, 3432, principally employed in the manufacture of serge, or in the tin and copper-mines and slate-quarries in the vicinity. This was the birthplace of the celebrated lawyer Dunning, who was created Baron Ashburton, and of William Gifford, the original editor of the *Quarterly Review*.

ASHBY-DE-LA-ZOUCH, a market-town of England, county of Leicester, and hundred of West Goscote, 17 miles north-west of Leicester. The town consists principally of one long street, and contains two churches, four chapels, a bank, savings-bank, theatre, and gas-works, and has a grammar-school, with ten exhibitions of L.10 each per annum in Emanuel College, Cambridge, besides several charity schools. The Ivanhoe baths, erected in 1826, are much frequented for their saline waters, which, as containing bromine, are found useful in scrofulous disorders.

The church of St Helen is a fine old building, containing the tombs of the Huntingdon family, and a "finger pillory." In the vicinity are the extensive remains of Ashby Castle, built by Sir William Hastings in 1480, and in which Mary Queen of Scots was confined. Population in 1851, 3762, principally engaged in the manufacture of stockings, hats, firebricks, or in the coal and iron mines of the vicinity. Bishop Hall was a native of this place.

ASHDOD. See AZOTUS.

ASHES, the fixed residue of combustible substances after they have been burnt.

ASHES were used in many ancient religious ceremonies. St Jerome relates that the Jews in his time rolled themselves in ashes as a sign of mourning. To repent in sackcloth and ashes is a frequent expression in Scripture for mourning and being afflicted for our sins. A heifer being sacrificed upon the great day of expiation, its ashes were distributed among the people, who made from them a sort of lustral water, which they sprinkled on such persons as had defiled themselves by touching a dead body or being present at a funeral (Numb. xix. 17).

The ancient Persians punished some great criminals by throwing them headlong down a tower filled with ashes to a particular height (2 Macc. xiii. 5, 6).

ASHFORD, a market-town of England, county of Kent, and hundred of Chart, 12 miles south-west of Canterbury, and 53 from London. It is pleasantly situated on a gentle eminence near the junction of the upper branches of the river Stour, and is a chief station of the South-Eastern Railway. Many of its houses are well built and handsome, and its principal street is nearly half a mile in length, and well paved and lighted. It has a fine old Gothic church, with a lofty well-proportioned tower, and many handsome monuments; four chapels, two banks, a savings-bank, market-house, assembly-rooms, a four-arch bridge over the Stour, and a free grammar-school founded by Sir Norton Knatchbull in the time of Charles I. Pop. in 1851, 4092.

ASHI, commonly called ASSER, the author of the Babylonian *Talmud*, was born at Babylon in 353. He is said to have given very early proofs of his acquirements. The Talmud is the expositions of the *Mishna*, delivered by him to his pupils in the Jewish College. He died in 426.

ASHLAR, a term used among builders for common or free stone roughly squared in the quarry. This term is likewise applied to different kinds of surfaces produced by tooling; hence we have axed, tooled, grooved, chiselled, and rusticated ashlar.

ASHMOLE, ELIAS, an English antiquary of the seventeenth century, was the son of a saddler in Lichfield, and was born on the 23d of May 1617. He went to London at the age of 16, and resided in the family of his uncle, James Paget, Esq., one of the barons of the exchequer, and then turned his attention to the law and various branches of literature. In the year 1638 he married, and commenced the business of attorney in London. When the civil war began, being then a widower, he entered into the king's service in the ordnance department. When residing in the

city of Oxford in that capacity, he entered Brazen Nose College, and began the study of natural philosophy, mathematics, and astronomy. Naturally inclined to grave and scientific trifles, he wandered into the wilds of astrological imposture, which was not a little encouraged by several eminent men of that age. From the same cause he entered keenly into the secrets of masonry, and made considerable additions to the history of that fraternity. From Oxford he removed to Worcester, where he was appointed commissioner of the excise; and soon after he became a captain in Lord Ashley's regiment, and comptroller of the ordnance.

When Worcester was surrendered to the parliament in 1646, Ashmole retired to London, where he became acquainted with the famous astrologers, Moore, Lilly, and Booker. Having removed to Berkshire in the year following, he added the knowledge of botany to his other acquirements. There he became acquainted with Lady Mainwaring, a well-jointured widow, whom he married in 1649; and although her estate was sequestrated on account of his loyalty, yet through the interest of Lilly and others he again recovered it, and afterwards settled in London, where his house became the resort of all the curious literati. A taste for chemistry, or rather alchemy, was produced by his conversation with William Blackhouse; and Ashmole, under a feigned name, published a work upon that subject. The next effort of his industry was a collection of the manuscripts of English alchemy, which he published under the title of *Theatrum Chymicum Britannicum*, in 4to.

His active industry was next directed to the study of antiquity and the investigation of records. Along with Sir W. Dugdale, he traced about this period a Roman road to Lichfield. Abandoning all other pursuits, he began to make preparations for his *History of the Order of the Garter*. Upon a visit to Oxford, he gave a full description of the coins bequeathed to that university by Laud; and about this time John Tradescant, the famous gardener of Lambeth, presented him with the collection of curiosities which both he and his father had procured.

On the Restoration, Ashmole came into high favour with the king, who made him Windsor herald, and employed him to give a description of the royal medals. The offices of commissioner and comptroller of excise were conferred upon him; and being called to the bar in the Middle Temple, he was afterwards admitted a fellow of the Royal Society. The university of Oxford conferred upon him the degree of doctor of physic; and several other employments and emoluments flowed in upon him. About this time his second wife died, and he married the daughter of his friend Sir W. Dugdale. In May 1662 he addressed his great work to the king, entitled *The Institution, Laws, and Ceremonies of the most noble Order of the Garter;* folio, London, 1672. In favour of his brother-in-law Mr Dugdale, he resigned his office of herald of Windsor; and when offered the office of garter king-at-arms, he declined it in favour of Sir W. Dugdale. About this time a fire broke out in one of the chambers of the temple adjacent to his, and consumed a library which he had been collecting during the course of 33 years, together with 9000 coins and many valuable antiquities; but his manuscripts and gold medals were fortunately saved. In 1683 he sent his manuscripts and curiosities to the University of Oxford, which laid the foundation of the *Musæum Ashmoleanum*, still in Oxford. On the death of Sir W. Dugdale, he refused a second time the office which that gentleman had enjoyed. He died at the age of 76, and was interred in the church of Great Lambeth.

ASHOVER, a town and parish in Derbyshire, containing 3482 inhabitants.

ASHRAFF, or USHRAFF, a decayed town of Persia, in the province of Mazunderan, about 8 miles from the western extremity of the bay, and 52 miles west of the city of Astrabad. It was formerly a very extensive city, and the favourite residence of Shah Abbas, the greatest of the Persian monarchs, who erected here a magnificent palace, now in ruins. It is said to have formerly contained 300 baths; but now it has not above 500 houses, which are thinly scattered through an extensive jungle. Lat. 36. 41. N. Long. 53. 32. E.

ASHTAROTH, and ASHTAROTH-CARNAIM, a town of Bashan (Deut. i. 4; Josh. ix. 10). It is now usually identified with Mezareib, which was built about 350 years ago by the Sultan Selim, and consists of a castle and store-houses to supply provisions to the pilgrims on their way to Mecca. On an elevated spot at the extremity of a promontory advancing into the neighbouring lake, stands a sort of chapel, around which are many ruins of ancient buildings.—Buckingham's *Arab Tribes*.

ASHTORETH, ASHTAROTH, or ASTARTE, in *Antiquity*, a goddess of the Sidonians, and also of the Philistines, whose worship was introduced among the Israelites during the period of the Judges (Judg. ii. 13; 1 Sam. vii. 4), and celebrated by Solomon himself, in compliment to one of his wives. In the reign of Ahab, Jezebel caused her worship to be performed with much pomp and ceremony; she had 400 priests; the women were employed in weaving hangings or tabernacles for her; and Jeremiah observes, that "the children gathered the wood, the fathers kindled the fire, and the women kneaded the dough, to make cakes for the queen of heaven." The best etymology of the word, and that approved by Gesenius, deduces it from the Persian *sitârah, star*, with a prosthetic guttural. Ashtaroth is the plural form, which, perhaps, denoted a plurality of images (like the Greek Ἑρμαί), or it was used as the *pluralis excellentia* among the Hebrews in words denoting "lord." Most modern scholars assume that Ashêrah was another name for Ashtoreth, whose worship has been identified with that of the Greek Aphrodite, which was introduced into Cyprus from the East.

ASHTON-UNDER-LYNE, a parliamentary borough in the county of Lancaster, hundred of Salford, and diocese of Manchester, on the northern bank of the river Tame, 6½ miles east of Manchester, and 197 north-west by north of London. The town is well built, containing many tasteful villas and handsome public edifices. It has three large churches; eleven dissenting chapels; a spacious town-hall; a good market-house; three banks; a savings-bank; a theatre; a mechanics' institute; with many week-day and Sunday schools. To supply in some respects the want of dispensaries and infirmaries, the working classes unite in paying a few pence weekly to a common fund, from which medicines are purchased, and the services of experienced medical men secured for their families. At a short distance to the north of the town are the infantry and cavalry barracks, erected in 1843 at a cost of L.42,500; and the union workhouse, erected in 1851 at an expenditure of L.12,000. Since the introduction of the cotton trade in 1769, this place has rapidly risen into importance. It enjoys many facilities for manufacturing industry, from coal being very plentiful in the neighbourhood, from three important railway lines passing through it, and from its being united by canals with Manchester, Huddersfield, and Derbyshire. In 1821 it had a population of only 9222, which in 1851 had increased to 29,798, chiefly engaged in spinning cotton yarn and weaving calico pieces by machinery in the numerous large factories. This town is of great antiquity, and still exercises many of its ancient feudal customs and manorial privileges. It is divided into four wards, governed by a mayor, eight aldermen, and twenty-four councillors; and since the Reform Act returns one member to the House of Commons. Market-days Tuesday and Saturday, and fairs on the 23d March, 29th April, 25th July, and 21st November.

ASIA.

Asia.

This division of the globe is distinguished by its vast extent; by the striking character of its interior geography; above all by the stupendous revolutions of which it has been the scene; and, lastly, by the high antiquity of its civilization, of which we can still faintly trace the precious remains. Stretching from the southern hemisphere into the northern regions of perpetual winter, it comprises within its bounds the opposite extremes of heat and cold; all the varieties consequently of the animal and vegetable tribes; and that still more interesting variety which the irresistible law of climate impresses on the human species. The surface of Asia, towering to its height far above the regions of perpetual snow, presents, when superficially examined, a confused mass of lofty mountains, diverging into an endless variety of inferior ridges, apparently without plan or system. But a more attentive survey discloses, amid the bold irregularities of nature, the same order and unity of design in the structure of this great continent, as in all the other works of creation.

Asia was the earliest abode of the human race; and, when all the other parts of the world were either uninhabited or sunk in barbarism, it was the seat of great empires and of flourishing and splendid cities, of commerce, of literature, and of all the arts of civilized life. But its early prosperity was blighted by the ruthless devastations of war; its populous cities were utterly destroyed, so that the spot on which many of them stood is now only marked by masses of ruins; their arts and literature have perished; and in such fragments of their writing as still survive, the meaning is buried under the almost impenetrable veil of an ancient and unknown character. In touching on the various topics which are comprehended under the designation of Asia, it must be remembered that in the following article we are to confine our attention to such general views of its geography, history, institutions, policy, and manners, as will not supersede a more particular description of its various states under their respective designations.

Name.

The name of Asia was at first applied by Homer and others of the ancient poets and historians to a small district of Lydia, occupied by a tribe called Asiones, who inhabited a city of the name of Asia. The Greeks, gradually enlarging their discoveries in those eastern countries, still retained the original name, until it embraced the whole of Asia Minor and the countries to the east; and it was at last applied to all the vast regions which subsequent discoveries have brought to light.

Limits.

The limits of Asia are in some cases marked out by nature, and admit of no dispute; in other parts they are not very clearly defined, and have been differently settled by geographers, according to their own notions of propriety or distinctness.

The continent of Asia extends over 77 degrees of latitude, or one-fifth of the periphery of the globe, and in the latitude of the Dardanelles, over 128 degrees of longitude, or very nearly one-third of the circumference of the globe under that circle. Its northernmost extremity is Cape Chelinskin, which projects into the Arctic Ocean in about N. Lat. 78°, in Long. 100° E. In the S. it extends to N. Lat. 1. 15. at Cape Bulus or Buro, or the S. end of the peninsula of Malacca; but if we include the Indian islands, Asia extends as far as S. Lat. 11°, or the parallel of Rottie, a small island to the S.W. of Timor. Its continental extremity in the W. is Cape Baba, in Asia Minor, opposite the island of Mytilene, in E. Long. 26. 4.; and its easternmost point is Cape Wostotchny, or the "East Cape," also called Cape Swernoi Tchukotsky, that is "the North Cape of the Tchuktches" (who call it Po-orten), and which must not be confounded with Cape Tchukotsky Noss, the latter lying more to the S. The continent of Asia is bounded in the N. by the Arctic Ocean, in the E. by Behring's Strait, which separates it from America, and by the Sea of Kamtschatka, the Sea of Okhotsk, the Sea of Japan, the Yellow Sea, and lastly, the Tong Haï, or East Sea. But the Japanese and several other groups of smaller islands, being appurtenances of the continent, it is evident that the North Pacific Ocean is the real eastern boundary of Asia. The southern limits are the Chinese Sea, the Strait of Malacca, the Gulf of Bengal, the Arabic Sea, the Gulf of Oman, and the Gulf of Aden; the latter four being limbs of the Indian Ocean The great Indian islands, the Philippines, Borneo, Sumatra, Java, Celebes, the Spice and Sunda islands, and all those smaller ones which, dotting the Sea of Banda, extend as far as the shores of New Guinea, are now generally reckoned to Asia, with which, indeed, they are so intimately connected by ethnological, religious, commercial, and political ties, that we are bound to consider them as appurtenances of that great continent. Asia consequently extends in the S.E. to the very threshold of Australia, or Oceania, but there are no natural limits separating them into two distinct portions of the globe. In physical geography, all or most of those islands form one vast volcanic group with the other islands along the east coast of Asia, the peninsula of Kamtschatka included. The limits of Asia in the W. are, the Red Sea, which separates it from Africa, the Mediterranean, the Dardanelles, the Sea of Marmora, the Bosphorus, and the Black Sea, on the side of Southern Europe; and the Ural and the Caucasus on the side of Eastern Europe. Between the Ural and the Caucasus there is a gap without natural limits, the great steppes of Western Asia advancing here into Eastern Europe; whence some geographers, in their eagerness to find natural limits where there are none, have substituted divers inconsiderable inequalities of the ground to serve as lines of demarcation between two large portions of the globe. But the Caucasus *is* a natural barrier, and if the plains to the N. of that great chain bear an Asiatic character, and are inhabited by Asiatic people, which cannot be denied, it is equally true that the steppe in its progress from E. to W. gradually assumes a European character, inasmuch as from a salt steppe, such as in Turkistan, it changes into a grass steppe, such as in the S. of Russia; and so far as regards the Asiatic character of the people, the influence of Europe through Russia is so great, that that difference also has all the appearance of being on the wane. The river Jaïk or Ural, between the Ural Mountains and the Caspian, affords a convenient line of demarcation on that side; not that it is a natural limit between two continents, or that the steppe on its right bank differs from that on its left; but because that river has been turned by the Russian government into a visible, fortified, and garrisoned line between various nations living under European influence in the W., and uncontrolled Asiatic barbarians in the E This view of the subject will be our excuse, if we refrain from saying much about the Obtchey Sirt, a ridge of low sand-hills between the southern foot of the Ural and the Wolga, marking the northern edge of the steppe, which some geographers have called a natural boundary, to fill up the gap on that side. It is worth noticing, that in the political division of Russia, no distinction is made between Europe and Asia, some of its governments, as for instance that of Perm, extending over both sides of the Ural Mountains.

Extent.

Asia contains a larger area than any of the other divisions of the globe, viz., including its islands, 12,960,000 square geographical miles; the area of America being 10,600,000, that of Africa 8,550,000, and that of Europe 2,560,000.

Asia. Islands.

The islands of Asia are:—in the Arctic Ocean, Nova Zembla, consisting of two large islands, and New Siberia, consisting of three islands of considerable extent discovered in the course of this century. Along the E. coast:—the volcanic group of the Kuriles; the Japanese islands, of which Nipon is the principal; the Lu-ku group to the S. of Japan; the large islands of Formosa and Hainan on the coast of China. Saghalia, opposite the coast of Mantchuria, was long believed to be an island, but is a peninsula extending over 8 degrees of latitude, and connected with the continent by a low, narrow, and sandy isthmus, a little to the S. of the mouth of the River Amur. In the S.E. and S.:—the Philippines, among which Luzon and Magindanao are the largest, and half a dozen others have areas surpassing or approaching those of Cyprus and Candia; the great islands of Borneo, Sumatra, Java, and Celebes; the Moluccas or Spice Islands, among which Gilolo, Ceram, Buro, and Amboyna, between Celebes and New Guinea; Nias, Batu, the two Pora, &c., on the W. coast, and Battam, Linga, Banka, and Billiton, on the E. coast of Sumatra; and, finally, the Sunda and Banda islands, a vast latitudinal archipelago, extending from the E. point of Java towards Australia and New Guinea, and composed of myriads of islands, among which the principal are in a direction from W. to E.; Madura, Bali, Lambok, Sumbava, Sandelbosh or Tshindana, Flores, Timor (250 miles long), Timor Laut, and Aru, which form a bridge as it were between Asia and Australia. In the Indian Ocean:—the Nicobar and Andaman Archipelagos, between the N.W. point of Sumatra and the mouths of the Irawaddy; the large island of Ceylon; and, on both sides of the 70th meridian E., stretching due N. from S. Lat. 8° nearly as far as the latitude of Goa, the archipelagos of the Tshagos, Maldives, and Lakkadives, all three composed of myriads of mostly very small islands of coral formation. In the Persian Gulf:—Ormuzd, Kishm, and Bahrein. In the Red Sea:—Perim, Arish (erroneously called Harnish), Farsan, and Dhalak. In the Mediterranean:—Cyprus, Rhodes, Chios, &c.

Physical aspect.

The surface of this vast continent is exceedingly varied. In some places it towers in stupendous mountains, forming four great chains, with subordinate branches, of different names. It often exhibits vast plateaux or elevated tablelands, of prodigious extent; in other points it stretches in plains little elevated above the level of the ocean; while in certain points it presents enormous hollows or depressions that are lower than the surface of the Black Sea. Humboldt computes the superficies of all Asia at 1,346,000 geographical square leagues. Of this a large proportion is mountainous, or raised in elevated plains. The same eminent authority estimates these as follows:—

	Sq. leagues.
The mountainous parts of Arabia, Beluchistan, or the plateau of Kelat, Kandahar, with the mountain ridges of India	240,000
The mountainous parts of China	54,400
The plateau of Gobi or Sha-mo	42,000
The plateau of Tibet and Ladak, between the Himalaya and Kuen-lun Mountains	41,000
The plateau of Persia	27,000
The Taurus of Asia Minor, Ararat, and the Hindu Kho	81,300
Of which that of Ararat alone is	3,500
The Caucasus, from Baku to Anapa	2,700
The Oural and Altai groups	3,400

The northern portion of Asia consists of a series of plains divided by mountains of small elevation, forming the comparatively low land of Siberia, intersected by several large rivers, and occupied often by extensive swamps. This region is estimated at about 400,000 square leagues. The central part of Asia, still imperfectly known to Europe, was till lately conceived to be one vast table-land, of irregular form, buttressed on every side by lofty mountains; but it now appears, on the contrary, to be traversed by long mountain chains.

Asia presents to the eye such a compactness of conformation, and its outlines are at the same time so diversified by deep indentures of the sea, forming gulfs and peninsulas of every shape and dimension, that neither Africa can be called more compact, nor North America more diversified. Every prominent feature of this vast continent is on a gigantic scale; and the aggregate of its mountains and rivers, its low plains and its elevated plateaux, surpasses those of the other divisions, not only in magnitude, but also by its contrasting variety.[1] Its mere steppe rivers approach the size of the Don and the Dniepr; and the second of its salt lakes, the Aral, is still larger, by 6400 square geographical miles, than Lake Superior, the largest sheet of water in America; while the combined superficies of all the American lakes would not suffice to cover the area of the Caspian. Its Indian Archipelago forms a world by itself, with which the West Indian Islands can be compared neither for extent nor importance; its mountains rise higher into the regions of eternal snow than the far-famed Chimborazo; it has its deserts of burning sand, and of frozen swamps, alike destructive to the human race. Nowhere is there such an exuberance of animal and vegetable life, not only spread over the whole continent, but also displaying itself within the narrowest limits, as the traveller rapidly descends from the crest of the Himalaya into the plain of Bengal. The same variety, the same contrasts, appear in its history. Asia, the cradle of mankind, the mother of religion, the nurse of civilization, where arts and letters were cultivated in the remotest times, contains within her inaccessible mountain forests numerous descendants of her primitive inhabitants, who still continue that brutish life which their forefathers led when the first vine was planted, the first hieroglyphic character carved in the rock.

Divisions.

Nature has divided Asia into six portions, of which each is so vast and so distinct from the other as almost to present a world by itself. These are Central, Western, Northern, Southern, Eastern, and Oceanic Asia. We place Central Asia at the head, because it is not only the nucleus of the whole continent, comparable to a huge citadel situated in the centre of a fortress, of which the other divisions are the bastions and ramparts, the peninsulas and islands the outworks; but also because the nations by which it is inhabited have exercised, from the remotest times, a most powerful influence on those of the other divisions, so that most of the great revolutions by which Asia has from time to time been convulsed since the very dawn of history, and which affected even Europe in such a degree as to change the whole ethnographical and political aspect of that continent also, can be traced back to commotions among the forefathers of those barbarous tribes of shepherds, who still wander in the cold and dreary steppes over which the Bogdo Ula towers in awful, majestic solitude.

Central Asia.

Central Asia, the greatest and highest table-land on the globe, extends between the Himalaya in the S., which se-

[1] According to Berghaus, there are 10 rivers in America, and 12 in Asia, the basin of each of which contains upwards of 10,500 German, or 168,000 geographical square miles. The united area of the former, the first of which is the Amazon, and the last the Rio Negro, is 324,500 German, or 5,192,000 geographical square miles; of which the basin of the Amazon occupies not less than 2,018,400. That of the latter, the Obi standing at the head with 924,800 geographical square miles, and the Tarim being the last, is 363,738 German, or 5,820,000 geographical square miles; giving a difference of 628,000 geographical square miles in favour of Asia. The total length of the 10 American rivers, windings included, is 76,640 geographical miles; that of the Asiatic, 98,448 geographical miles: difference in favour of the latter, 21,808 geographical miles. Yet the system of the Marañon in the former stands unequalled by any in the world.

Asia.

parates it from India, and the chain of the Altaï, with its eastern continuation, the Daurian Mountains, in the N., towards Siberia. Its western boundary is the Bolor Dagh, a lofty range beginning at the Hindu Koh in E. Long. 72°, by which it is separated from Turkistan, and which stretches due N. as far as the steppes of the Khirgises, in about N. Lat. 46°. In the E. it is bordered by China and Mantchuria. From the junction of the Hindu Koh and the Bolor Dagh, a snowy range extends E. in the 35th parallel, as far as the Alps of Shensi, in China; its western portion, towards the Bolor Dagh, is called Thsun-ling; its eastern, Kwan-lun or Kuen-lun,—both names meaning Blue or Onion Mountains. From the Kuen-lun the Sive-shan and Amie Gangar Ula branch off N.E., towards the Lake Kuku-nûr. Another high range shoots from the central portion of the Bolor Dagh, N.E. and E., far into the interior. It is called Tengri Dagh by the Turks in those parts, Thian-shan by the Chinese—both of which names signify Celestial Mountains; and Mus Dagh, or Ice Mountains, by the Mongols. Separated from the Thian-shan by an intervening portion of the desert of Gobi, extends the snowy range of Gadshar or In-shan along the northern frontiers of China. The highest peak of the Thian-shan is the celebrated Bogdo Ula, or Holy Mountain, one of the loftiest mountains in Asia, at the western foot of which lies the volcano of Petshan.

Divisions of Central Asia.

The four chains of the Himalaya, the Kuen-lun, the Thian-shan, and the Altaï, are, in the whole, parallel to each other, and divide the table-land of Central Asia into three plateaux of decreasing elevation and different dimensions, namely, Tibet, High Tartary, and Mongolia.

First terrace, or Tibet.

The highest terrace is Tibet, between the Himalaya and the Kuen-lun, and the Bolor and China; between N. Lat. 28° in the extreme S., 36° in the N., and 39° in the extreme N.E.; and between E. Long. 68° and 98° from W. to E. Ladakh in the extreme W., Kham in the E., and Tangut in the N.E., are appurtenances of Tibet. The level of Tibet is not equal, its surface showing numerous and extensive depressions, with steppe rivers flowing into salt lakes without outlets; the valleys of the Indus, the Dzangbo and the Yang-tse-kiang (in Kham), especially that of the Dzangbo, are also much below the general level. The highest plateaux are around the culminating point of the Himalaya, the Hindu Koh, the Bolor Dagh, and the Kuen-lun, on the borders of Turkistan; and Ritter thinks that the plateaux around Lake Kuku-nûr are quite as high. Their elevation is not accurately known, but they are both higher than the plateaux stretching from the sources of the Sutledj E. towards the sacred mount Kaïlasa, which rise 16,800 feet above the sea, increasing in height further E. The average height of the other Himalaya plateaux is about the same. Mount Purkyul or Tashgong, on which Lieut. Gerard reached, in 1818, an altitude of 18,210 feet, is 21,300 feet high; but the highest known peaks of the Himalaya do not lie on Tibetan territory. According to all appearance the peaks which rise above the high table-land on the borders of Turkistan, and those around Lake Kuku-nûr, probably equal in elevation the highest peaks of the Himalaya. In Kham, also, which is intersected by numerous valleys encompassed by precipitous Alpine rocks, there are mountains of stupendous height, and mountain passes lying 18,000 feet above the sea, over which, however, the Chinese more than once penetrated into Tibet with armies of 100,000 men. The climate of Tibet is very severe, the winters being almost insupportable, but the summer season in the lower valley of the Dzangbo is genial, the country producing grapes, peaches, and other choice fruit, in abundance. Tibet contains the sources of the Indus, the Dzangbo, the Yang-tse-kiang, and the Hoang-ho, the latter two being in Tangut. The largest lakes, which are all surrounded by vast and excellent pastures, are Kuku-nûr in Tangut, and Tengri-nûr in Tibet Proper. Our scanty knowledge of Tibet has lately received a valuable addition in the journal of the Rev. Mr Puch, a French missionary, who proceeded from Peking, through Mongolia and Tangut, to L'Hassa, the capital of Tibet, which he left for China by the road through Kham. An English translation of his MS. journal was recently published under the auspices of Lord Palmerston.

Second terrace, or High Tartary.

The slope of this terrace, which comprises Chinese Turkistan, the western portion of the desert Gobi, and the southern portion of the Chinese government Kan-fu, is from the high plateaux of the Bolor Dagh E., towards the desert Gobi. Its highest tracts lie in the Bolor Dagh, the Thian-shan, especially around the Bogdo Ula, the Tsung-ling and Kuen-lun, and in the far E., in Kan-fu, along the snowy Tangut range, the slope of which towards the Gobi seems to be very rapid. There the province of Kan-fu penetrates edgewise into Mongolia, extending N. and W. towards the Altai Proper. The central and eastern portions of High Tartary are occupied by the southern Gobi, which lies much below the general level of the terrace. The elevation of this terrace is considerably lower than that of Tibet, as appears from the genial climate of Chinese Turkistan, which is said to produce grapes, pomegranates, peaches, and other choice fruit of southern climes. The river Ta-rim, swelled by numerous affluents descending from the Bolor, the Tsung-ling and the Kuen-lun, traverses the whole of Chinese Turkistan from W. to E., and empties itself into the steppe lake Lob, on the borders of the Gobi, after a course of about 1000 geographical miles. It is also called Erghö-göl, and Yar-kiang Daria, which, however, is but the name of a large southern affluent washing the walls of Yar-kiang. The natives and the Chinese contend that the Ta-rim was once connected with the Hoang-ho, of which it formed the upper course, but that the connection was interrupted in consequence of the level of the Gobi having been raised by volcanic power. Besides the Lob, there are the large steppe lakes Babakul and Bosta, at the foot of the Thian-shan. Of the desert Gobi more will be said under the next head, and Kan-fu, although cultivated in many parts, partakes on the whole of the desolate character of the other highlands and plateaux in this region. The climate of Chinese Turkistan is exceedingly dry, rains being rare phenomena, whence all cultivated fields are watered by artificial irrigation. The winters are very severe. The original inhabitants of the extensive tracts watered by the Ta-rim were Tadjiks, a nation akin to the Persians, and who are also, but erroneously, called Bokharians, because they are very numerous in Bokhara. The Tadjiks were conquered by the Turkish tribe of the Usbeks, who established several small principalities, gave their name to the country (Turkistan), and ruled over it till they were subjugated by the Chinese in 1757. Thence the European name of Chinese Turkistan. The Chinese themselves call it Thian-shan-nan-lu (the province along the southern foot of the Celestial Mountains), and it is a portion of their "Si-yu," or "West Country." There are also many Mongolish tribes in the country.

Third terrace, or Mongolia.

The most elevated plateaux of Monglia, which are overtopped by some of the loftiest peaks in Asia, lie in the S., in the In-shan, on the borders of China, and the Thian-shan, on the borders of Chinese Turkistan. They slope gradually down towards the Altaï, and the desert of Gobi, which occupies the central parts of Mongolia. The level of the terrace, consequently, varies very much, but measurements have only been made in Songaria, along the Altaï, and along the great caravan road which leads from Peking to Kiakhta, on the frontiers of Siberia. On ascending the plateau from Peking, the traveller is almost suddenly transported from a southern clime to a cold, dreary table-land, resembling Siberia much more than China. The point where the road crosses the great Chinese wall, lies about 5100 feet above

Asia.

the sea, and marks the beginning of the desert of Gobi; the level of Zaghan-bal-ghassu, further N., is 4200 feet; near Zakil-dakhan begins a sandy desert dotted with salt lakes, which lies much below the plateaux to the S. and N. of this tract, and seems to be the dried-up bed of an inland sea. It extends as far as Durma, where the soil changes from sand to a hard salt clay, producing saline plants, and strewn over with large fragments of rock, mostly porphyry and jasper, while in other places the steppe is literally covered with chalcedonies and agates. This tract is about 2400 feet above the sea, and the dreariest of the whole Gobi. The level rises in the direction of the Bussu-tchilon, or Belt Mountain, a steep, high wall of syenite rock, extending E. and W., and standing on a basis 3480 feet high. On the northern side of that conspicuous ridge, the plateau rises again to 4600 feet, at Djirgalanta, whence it slopes down to 4000 feet, at Erga or Urga, a large town at the foot of the lofty, wood-clad Khan Ula, and the capital of the Khalkhas Mongols. Erga lies at the northern foot of the Guntui range, which marks the beginning of the Gobi, but not that of Mongolia, on the side of Siberia.

Desert of Gobi.

Gobi is a Mongolian name signifying a country without trees and water, the same as the Chinese Shamo, and no less appropriate than the well-known terms Sahara and Ahkaf. It extends 1600 geographical miles from S.W. to N.E., with a width varying between 250 and 500 geograpical miles, and occupies the central portions of both the second and third terrace of Central Asia. The Gobi is one of the most desolate tracts on the face of the globe. The utter absence of fresh water, the deceiving salt lakes glittering in the midst of inhospitable solitudes, the whirling clouds of dust and the myriads of gnats which pursue the weary traveller in the summer, combined with the intense cold, the icy blast of hurricanes, and the all-burying snow storms of the winters, are phenomena no less redoubtable than all the horrors of the Sahara. But the Gobi also has its oases of luxuriant pastures around most of its salt lakes and along the steppe rivers, where the wandering Mongols pitch their tents of felt, and rear large herds of cattle, sheep, camels, and horses. The part occupied by the Chinese province of Khan-fu seems to be the least desolate; it is watered by two considerable steppe rivers, the Thola and the Bulon-ghir, and contains many settled inhabitants as well as some towns of importance. Our scanty knowledge of southern Mongolia has lately received most valuable additions through the journal of Mr Puch.

Mongolia Felix.

From the Guntui Mountains, in the territory of the Khalkhas Mongols, the Khing-khan, a high range, runs E. towards Mantchuria, and another, under various names, towards the Altaï in the W. This extensive mountain system is composed of the Khangai, the Guntui, and the Tangnu chains, and forms a curve connected in the W. and E. with the curve of the great Altaï system; and between the two curves lies an immense longitudinal tract, divided by northern branches of the Guntui and Tangnu into three basins. In the eastern basin are the head waters of the Amur; in the central one, those of the Selenga, which, after having crossed lake Baikal, assumes the appellations of Angara and Upper Tunguska, under which name it joins the Yenissei, of which it is the principal affluent; the western basin, finally, is watered by the upper course of the Yenissei, which rises here. But, although this great tract contains the sources of three of the greatest rivers of Asia, its elevation, except towards Erga, is much lower than that of High Mongolia, and not much above that of Southern Siberia, towards which it slopes down very gradually. Kiakhta, the frontier town of Siberia, lies 2100 feet above the sea. The political frontiers of Russian and Chinese Asia have been fixed across the tract without any consideration of natural boundaries, so that the northern portion belongs to Siberia, and the southern to Mongolia. It is inhabited by various Mongolian tribes. This circumstance, together with the abundance of water, the luxuriant pastures, the wooded mountains, and the comparatively genial climate, have given this tract the title of *Mongolia Felix*, a name not inappropriate, considering the contrast it offers to the adjacent Gobi. Western Mongolia, also, which is watered by the great steppe river Djabagan, which flows into Lake Ike Aral, is, comparatively speaking, a good country.

Songaria.

The westernmost part of Mongolia, or the plateau of Songaria, lies between the Altaï and the Thian-shan, along the western slopes of a high chain connecting those great ranges in a direction from N. to S. In its highlands there are peaks covered with eternal snow, and in the N. lies the Bielukha, the highest peak of the Altaï, to which Mr Gebler, who visited the country in 1833, assigns an elevation of 11,723 feet. In Songaria are the sources of the Bukhtarma and Erisis, which are the main feeders of the great Siberian river Irtish. It contains several large salt lakes, as the Kizilbash, the Alakta-gol, the Issi-gol, and the Dsaisang; and it slopes rapidly down towards the great Balkash, the elevation of which is under 1800 feet. Songaria is a thriving Chinese province, with a motley commercial, agricultural, and nomadic population of Mongols, Turks, Tadjiks, and Chinese, most of the latter being exiled or transported criminals.

Western Asia.

Western Asia contains Turan or Turkistan in the N.; Iran or Persia, Afghanistan, and Beluchistan, in the E. and S.; the Caucasus, the Armenian table-land, and Asia Minor, in the W.; and Arabia with Syria in the extreme W. and S.W. Its natural limits are,—in the N., none, although the low western spars of the Altaï are sometimes called so; in the E., the link between the Altaï and the Thian-shan (true Altaï of Humboldt), and the Bolor Dagh towards Mongolia and Chinese Turkistan, and the Indus towards India. The western and southern limits coincide with those of Asia. Western Asia extends 3000 geographical miles from S.W. (Babelmandeb), to N.E. (Altaï), and 2100 geographical miles from W. (Dardanelles), to E. (Bolor Dagh).

Turan or Turkistan

Turan or Turkistan comprehends the original seats of the Turkish race, that is, the Osmanlis, the Turkomans, the so-called Tartars (or, better, Tātărs) in European and Asiatic Russia, the Khirgises, the Usbeks, the Kara Kalpaks, the Bashkirs, and many other tribes, many of which have left their original homes to settle in distant countries.

Steppe of the Khirgises.

This vast tract measures 1300 geographical miles from W. to E., and about 500 from N. to S. It is partly a salt steppe, partly a grass steppe, the latter characteristic prevailing on the side of Siberia, into which it gradually merges. Low offshoots of the Altaï fill its northern parts. It contains a great number of salt lakes and steppe rivers. Among the former, the Balkash, on the borders of Songaria, has an area of 4800 square geographical miles, and is one of the largest in Asia; the Alaktu-gol, the northern Tenghiz, and the Tchurch-edshin, are considerable. The Ishim and Tobol Rivers, and other affluents of the Irtish, water the north; the steppe rivers Karaturgai, Naru, and Sarisin, the centre; and the Tchui, which issues from Lake Issi-gol, and empties itself into Lake Kaban Kulak, after a course of 700 miles, separates the steppe of the Khirgises from the slopes of the northern Bolor Dagh. Of the Caspian and the Aral, more will be said under the head "Turkistan." The Khirgises, a Turkish tribe, call themselves Kazaks or Cossacks, and are divided into three Hordes (a corruption of "ordu," tribe); namely, the Great Horde in the E., under the nominal supremacy of China and the Khan of Khokan, and the Little and Middle Hordes over which Russia has obtained a protectorate, which is more and more assuming the character of sovereignty. The fortified line of the River Ural is still the principal boundary of the Russian empire towards the

Asia.

steppe of the Khirgises, but forts garrisoned by Russian Cossacks have of late been erected along the lower course of the Sihûn, and the materials of three schooners having been conveyed on waggons from Orenberg to Lake Aral in 1847–48, that inland sea is now navigated by Russian vessels manned by Russian sailors.

Turkistan Proper.

The surface of Turkistan Proper shows a greater difference of level than any other known country, the highest peaks of the Bolor and Hindu Koh, together with the table-lands over which they rise, vying with those of the Andes and Himalaya; while the level of the Caspian lies 83. 67. below that of the Black Sea, and a large tract around it is also below the level of the ocean. The area of the Caspian contains 118,000 square geographical miles, and is as large as that of the Baltic. Lake Aral was carefully surveyed in 1847–48 by a Russian naval expedition under Captain Butakow, assisted by Captain Maksheyef, but the astronomical observations were made by Mr Lemm in 1846. The lake extends between the parallels of 43. 42. 41., and 46. 44. 42. N. Lat., and 58. 18. 47. and 61. 46. 44. E. Long.

The Aral, a large gulf called the Little Aral included, covers an area of 17,600 square geographical miles, or only one-half of that which it was until lately believed to have. It contains many islands, but only a few good harbours, and receives no rivers besides the Sihûn and the Djihûn; the supposition that the Djan Daria reaches the lake having not yet been substantiated. Its water is salt, though less so than that of the ocean, and near the mouths of the rivers so little brackish, as to be drinkable; its average depth is between 10 and 15 fathoms, its greatest, 37 fathoms; it is exposed to sudden and violent squalls, and abounds with fish, but there are no seals, of which there are such great numbers in the Caspian. Connected with the Aral in the S.W., is the large swamp Aibuyir or Laudan, which extends S. as far as 42. 30.[1]

The plains of Turkistan rise very gently towards the Bolor and Hindu Koh, the whole western slopes of which are a high, Alpine country, well wooded, and abundantly watered by the feeders and affluents of the Djihûn and Sihûn. The sources of the Sihûn, or Sir Daria, lie near the culminating point of the Bolor and Thian-shan, on the high table-land inhabited by the Karakalpaks, or Black Caps, a tribe of Turkish nomads who call themselves Buruts, and differ very little from the Khirgises. After a course of 1200 geographical miles, or perhaps less, and changing from W. to N., and again W., the Sihûn flows into the Aral through several channels, none of which is deeper than three feet. The Djihûn comes from the high plateau of Pamir (16,800 feet), where its sources were discovered by Lieutenant Wood; its course lies W. and N.W., and it forms a large delta at its mouth. Its total length is about 1400 geographical miles. The deepest of its embouchures has about 3 feet water. There can be little doubt that the Djihûn, the ancient Oxus, once emptied itself into the Caspian, a fact which was known by Jenkinson in 1558; Abulghazi, Sultan of Khozwarem, mentions it in his *History;* and a Russian survey all but confirmed it about thirty years ago. The ancient bed is still distinguishable, and in many parts filled with water. The climate of Turkistan, which lies between the isotherms of the rainless regions, is exceedingly dry, whence all cultivation ceases where there is no running water, or such as is obtained from the numerous canals of irrigation. But wherever fresh water is found, the land is well cultivated, and yields an abundance of grain and fruit of most excellent quality: the grapes, melons, peaches, oranges, and other exquisite fruits are renowned in Asia. The waterless districts are either salt steppes or sandy deserts, especially near the Caspian, and between the Aral and its two tributaries. A great proportion of the settled population of Turkistan are Tadjiks.

The country contains the independent Khanats of Khiwa, Bokhara, Kunduz, and Khokand; the two latter of which occupy nearly the whole tract of the western slopes of the Bolor Mountains, the high plateaux of the centre along the whole of the range being inhabited by tribes of Karakalpaks and other Khirgises, who are but little dependent on the neighbouring princes.

Iran, or Persia, with Afghanistan and Beluchistan.

A western continuation of the Hindu Koh, the range of Khorassan, and the Damani Koh, separates Iran from Turan, and decreases in height as it approaches the south-eastern corner of the Caspian. There the lofty chain of the Albors or Elburz rises suddenly, and trending W., connects the system of the Himalaya with the Caucasus and the Taurus. The highest peak of the Hindu Koh, in this part, is the Kohi Baba, N.E. of Kabûl, which rises 16,900 feet above the sea; in the Elburz, the volcanic peak of Demawend is 13,870 feet high. The northern part of Afghanistan is very mountainous; and the table-land of Kabûl is about 6000 feet high. To the W. of it, there is a great salt desert, in the midst of which are the fertile oases of Herat and Kandahar. On the plateau of Afghanistan are the sources of the steppe rivers Murghab, which flows N. into the plain of Turkistan; Heri Rud, which waters Herat and Meshed; and Hilmend, the most considerable of the three, which empties itself into Lake Hamun, on the borders of Persia. Beluchistan is a plateau, the interior of which is but imperfectly known. The slope of the plateau of Afghanistan towards the plain of the Indus is very abrupt, the mountain chains having in many localities the aspect of steep rock walls. Persia is a plateau from 3500 to 4000 feet above the sea, and nearly on all sides encompassed by lofty and rugged chains, through which narrow mountain passes lead into the interior. But it is open towards Western Turkistan and Central Afghanistan. Between Abushehr (Bushire) on the Persian Gulf, and Shirauz, there are no less than seven terraces. A large portion of the interior of Persia is occupied by a great salt desert, diversified in some places by highly fertile oases. On the whole, the interior of Persia is a miserable country, resembling the central parts of Arabia, and lying like them within the isotherms of the rainless region. But Mazanderan, the narrow district between the Elburz and Caspian, has a moist climate, in which trees and plants of every description grow most luxuriantly. In the west, also, the slopes of the Kurdistan Alps, and the Pushli Koh towards the Tigris, and the extremity of the Persian Gulf in Khuzistan, are well watered and highly productive. The latter chain is a portion of Mons Zagros of the ancients. The peak of Rowandiz, to the S. of Lake Urumiyeh is of enormous height. But the highest portion of Persia is the province of Azerbijan, which, however, belongs to the plateau of Armenia. See Persia.

The Armenian plateau.

The Armenian plateau occupies a large tract between the Anti-Taurus and the Caspian, and the plains of Mesopotamia and the Caucasus. It is of great elevation; the plain of Erzrûm being 6114 feet above the sea, which is about the average height of the whole plateau. Above this basis, a great number of peaks are covered with eternal snow, among which the Ararat is the highest (17,266 feet) The climate is very dry, but much less so than that of Iran and Turan; and there being an abundance of running water, cultivation is carried on with success on plains which otherwise would be barren. Deep valleys encompassed by steep rocks furrow the table-land in every direction; there the settled population accumulates, the nomadic tribes, chiefly Kurds, preferring the uplands. On the Armenian

[1] Ritter's Review of Maksheyef's description of Lake Aral, in *Monthly Bulletin of the Geographical Society in Berlin,* May 1852.

Asia.

plateau are the sources of the Tigris and the Euphrates, which flow into the Persian Gulf through a common channel; the Aras or Araxes, and the Kurtwa tributaries of the Caspian; and the Tchoruk and the Kizil Irmak, which empty themselves into the Black Sea. Among the lakes, two belong to the largest in Asia, namely, Urumiyeh (about 300 miles in circumference) or Azerbijan, and Lake Van (about 190 miles in circumference) on the Turkish territory. Mr Layard supposes the latter to be the real source of the Tigris, issuing from it through a subterranean channel. From the table-land of Armenia, the Elburz branches off E. towards the far Hindu Koh; the Kurdistan Alps branch off S.; and the Taurus and Anti-Taurus W. In the extreme N., along the Black Sea, an intricate system of irregular chains connects it with the mountains in the N. of Asia Minor, and, in an opposite direction, with the Caucasus, from which the plain of the Kur separates it further E.

The lofty chain of the Caucasus, which divides Asia from Europe, extends 600 geographical miles, between the Black Sea and the Caspian, in a direction from N.W. to S.E. The average height of its crest is 8000 feet; but upwards of a hundred peaks rise to a considerable elevation above it: the highest are the E. and W. summits of Elburz, respectively 18,513 and 18,449 feet, and Karbek 16,844 feet. The Caucasus is celebrated for the sublime wildness of its scenery. Among its wooded mountains rise the Kuban, the Kuma, and the Terek, in the N., the former joining the Black Sea, and the two latter the Caspian; and several of the head waters of the Kur, which flows into the Caspian in the S. It shelters hardy tribes of mountaineers, who have long maintained their independence. See CAUCASUS.

Syria and Arabia.

Syria is a link between Asia Minor and Arabia, its lofty mountains being connected in the N. with the Taurus, and in the S. with Mount Sinai, and the coast range of Northern Hedjaz. The principal southern portion of the Syrian mountains is the Libanon, which the valley of the Orontes, the Cœle-Syria of the ancients, divides into Libanus and Anti-Libanus. The highest peak is the Djebel Sheikh, or Great Hermon, the southernmost buttress of the Anti-Libanus, which rises abruptly over the plateau of Northern Palestine, and attains an elevation of at least 13,500 feet, and very probably 14,000 feet. Its summit is covered with eternal snow, whence the Arabs call it also Djebel-el-Teldj, or Snow Peak. See SYRIA.

Arabia is a table-land, except in the extreme N., where it slopes down to a low sandy desert. The elevation of the central plateaux varies between 3000 and 5000 feet, but those in the S., in Hadhramaut, are 8000 feet above the sea. The whole N. and centre of Arabia are within the isotherms of the rainless regions, but the southern portions are refreshed by tropical rains; the volume of which is, however, far from being the same everywhere, much depending upon local causes. See ARABIA.

Northern Asia, or Siberia.

Siberia was originally the name of a Turko-Mongolian Khanat, comprehending a large tract between the Ural and the Ob, and extending south over a portion of the steppe of the Khirgises. It was one of the fragments of the huge empire of Zinghis Khan, and took its name from the capital Sibir, of which some remnants are still visible near Tobolsk. The Kossack Yermak conquered Sibir in 1581, for his master, Ivan IV., surnamed the Terrible, Czar of Muscovy; and the Russian dominion having gradually extended itself over the whole of North Asia, the name of Siberia became the general designation of that vast region, as being the most prominent among the several territorial divisions of that part of Asia. The S. of Siberia is a mountainous country occupied by the Altaï system, except a tract towards the steppe of the Khirgises. Its greater western portion between the Altaï, the Ural, the Polar Sea, and the River Lena, is an immense plain of but little elevation above the sea; but Eastern Siberia, between the Lena and the seas of Okhotsk and Kamtschatka, is a mountainous country, except along the shores of the Polar Sea. The name *Altaï* is now generally, but improperly, given to the whole of the great mountain system on the borders of Central and Eastern Asia; but originally it only designated its westernmost portion around the sources of the Irtish, Obi, and Yenissei. The highest peak of that Altaï is the Bielukha in Songaria, which is covered with eternal snow, and 11,700 feet high, according to Gebler, or 12,790 according to Tchihatchaf. In both the Turkish and Mongolian languages, Altaï Dagh or Tau means *Gold Mountain;* and the abundance of that precious metal fully justifies the name. The chain of Ergik Targak runs E. towards the Baikal, and as far as that lake the system is called Western Altaï. The Baikal has salt, or rather brackish water, covers an area of 10,000 geographical square miles, and is surrounded on all sides by spurs of the Altaï.

The chain, improperly called *Eastern Altaï*, is composed of several chains, which are known by the collective name of the Daurian Mountains. The principal chain, which stretches far E. between Siberia and Mantchuria, is distinguished by its rounded summits, whence the Russians call it Yablonoi-Khrebet, or Apple Mountains. It is also called Stannowoi-Khrebet, or Stony Mountains: its Mantchu name is Khing-khan-tagurik. In the centre of the Daurian Mountains are the rich gold mines of Nertchinsk, a town situated on the Shilka, or northern branch of the Amur. Further E. along the sea of Okhotsk, are the Aldanian Mountains, with Mount Kapitan, 3780 feet high; and the extreme N.E. of Asia is traversed in every direction by the mountains of the Tchuktches, through which the Anadir meanders towards the entrance of Behring's Strait. These chains, together with their numerous northern spurs, are covered with magnificent forests, which, in the Aldanian Mountains, in N. Lat. 60°, reach an elevation of 2100 feet. Both the western and eastern chains are rich in various metals, and the gold mines yield precedence only to those in California and Australia. The great peninsula of Kamtschatka is a volcanic country, traversed from N. to S. by a lofty range, the southern portion of which is distinguished by a countless number of extinct volcanoes, situated along its western slopes. The northernmost, in N. Lat. 54. 40., is the Shiwelutch, and the highest the Kliutchef, 14,790 Parisian feet high, as measured by Erman. In the interior, especially in the Baidar Hills, are plateaux 1800 feet above the sea and covered with lava. The southern tracts of Siberia, those which belong to *Mongolia Felix*, as well as the valleys of the Altaï, and the plains along its northern foot, are a fertile country; and although the winters are very severe, the summers are hot, and the soil yields abundant crops. But the steppes in the centre, and still more those in the north, have a very different character.

The Ural extends from the shores of the Arctic Ocean, in N. Lat. 70°, to the middle course of the river Ural in N. Lat. 51°. The mountains in the island of Nova Zembla (among which Mount Glassowsky attains an elevation of about 2500 feet), are a northern continuation of the Ural; with which, in the extreme south, are connected the plateau of Uptchei Syrt, between the Volga and the Don; the low ridge of Mugodjar, which terminates in the steep plateau of Usturt, between the Caspian and the Aral, and other low hills in the steppe of the Khirgises. The main and central portion of the Ural consists of a principal western chain, from which many spurs branch off towards Russia; and two parallel chains on the Asiatic side, the easternmost and lowest of which is the Irmel, which rises abruptly over the steppes of Siberia. The highest summits are a little to the E. of, and detached from, the main chain, near Bogoslowsk, in Lat. 60°; they attain an elevation of from 8000 to 9000 feet, and

Asia.

among them the Daneshken Kamen is considered to be the highest. The highest summits in the S. are the Yurma, the Toganai, and the Iremel, none of which rises more than 4000 feet above the sea. The Pawdinski Kamen was formerly believed to be the highest mountain in the Ural, but its recent measurements have shown that it is not higher than the Taganai, viz., 3500 feet. Generally speaking, however, the average height of the crest of the whole Ural is not considerable. Near Katherinenburg, where the grand road from Europe to Asia leads over it, it is only 1600 feet; the highest point of the road between Miyask and Slatousk is not above 1800 feet; and the town of Katherinenburg lies only 900 feet above the sea. The northernmost portion is called the Obdor Ural; south of it the Poyos, the Werschourian, the Katherinenburg, and the Bashuirian-Ural. The Ural is rich in minerals, especially in the district around Katherinenburg, and its gold and platinum mines are the richest in the Old World.

Level of Siberia.

It has already been observed, that the basin of *Mongolia Felix* is a plateau much less elevated than High Mongolia, and that it slopes gradually down towards the low steppes of Siberia, a fact which could not escape the notice of those who had an opportunity of observing the gentle current of the great Siberian rivers. Kiakhta, on the steppe of the Selinga, on the frontiers of China, lies 2100 Parisian feet above the Polar Sea; the elevation of Lake Baikal, into which the Selinga flows, is 900 feet lower, or 1200 feet; that of the Irtish, near Tobolsk, about 500 miles from the Obi Gulf, is 110 feet; that of the Obi at Barnaul, in the midst of the northern spurs of the Altaï, is only 360 feet. But Siberia, around and east of the Baikal is more elevated, and the low steppes begin in a much higher latitude. They increase in desolation towards the N., and between the 70th parallel and the Arctic Ocean they present the aspect of an immense frozen swamp, the surface of which, thawing up in the summer, covers itself with moss. These dreary plains or Tundra, were first and graphically described by the Russian Admiral Wrangell.

Southern Asia.

This division comprehends Hindustan, Burmah, Siam, Laos, and Cambodia, and though not in extent the largest, it is in many respects the most important portion of Asia.

Hindustan.

It is not easy to give the extent of Hindustan with precision, from the extension given to the appellation by geographers; but if we carry a straight line from Cape Comorin, its southern point, to the northern boundary of Cashmere, its extreme length may be stated at 27° of latitude, or about 1890 English miles. Its form is an irregular triangle, the greatest breadth of which, in Lat. 24° N. from the mouth of the Indus, to the mountains of Cassay in Burmah, extends from Long. 69° to 92° E., a distance of about 1250 English miles. This area has an exceedingly varied surface, and contains a very mingled population. The northern and western portions are diversified by mountain ranges, often exceedingly steep and rugged; especially in the northern provinces, where they may be considered as spurs of the vast Himalaya chain; and also in the less lofty range which skirts the western coasts of the Indian peninsula, distinguished by the name of Western Ghauts, which in some points attain an elevation of from 4000 to 5000 feet. The mountains of the eastern side are far less elevated. A great portion presents extensive valleys, or vast plains, watered by noble rivers; but in a few places there are wide deserts, as on the eastern side of the Indus; and where water is deficient, as on portions of the eastern coast, there are sandy wastes. But in the plains traversed by the Ganges and its numerous affluents, by the Bramahputra, the Ganga, the Nerbudda, and the Kristna, the soil is of surprising fertility, and often presents scenes of varied beauty. Where nature has denied the usual means of irrigation, art has often supplied the deficiency by artificial canals, and an enormous population finds the means of subsistence. These riches are not without alloy. Wherever water stagnates, especially in the midst of thick jungle, that locality becomes the chosen abodes of malignant fever and of spasmodic cholera; scourges that annually carry off multitudes in every part of India. The mountain streams for ages have afforded golden sands; eclipsed however in latter times by the riches of the Ourals, of California, and Australia. The central part of Hindustan affords diamonds; and for ages the only locality of that gem was believed to be Golconda.

The population of Hindustan consists of various races. The original inhabitants are said to be still represented by some mountain tribes, that may be yet distinguished from the Hindus, the Malayans, and the Cingalese; and the less swarthy Mahometan population are descendants of Arabian, Persian, and Tartar immigrations. See HINDUSTAN.

Burmah.

The country now known under the name of Burmah comprehends the kingdoms of Ava and Pegu. Its northern boundary is the mountains of Assam; its western, British India and the Gulf of Bengal; the southern, the Malayan peninsula; and the eastern is Siam. Its extent is not well defined; but it appears to stretch from the 9th to 26th degree of N. Lat., or a length of about 1080 English miles, with a varying breadth from 600 to 240 English miles. The northern portions are mountainous, and afford gold, silver, sapphires and rubies; but the principal part is a vast plain, watered by the noble Irawaddy and its affluents. The lower portions, about Rangoon and Pegu, are low and swampy. The whole is the seat of a warlike people, that have twice braved the armies of British India with more than Eastern courage. See BURMAH and AVA.

Malaya.

Malaya or Malacca is a narrow peninsula extending into the Indian Ocean, with a length of about 700 English miles, and a mean breadth of 150; and it has numerous fine harbours. On the coasts are some European settlements, one of which, Singapore, belongs to Great Britain. The interior is a longitudinal mountain chain, from which various arms descend on either hand. The interior is imperfectly known to Europeans. The native Malays are an enterprizing, restless, vindictive race, much given to navigation and to piracy. In former times, they appear to have spread themselves over a considerable portion of the Pacific. See MALACCA.

Siam, Laos, Cambodia.

Of the interior of Siam, Laos, and Cambodia, we know little. They occupy two extensive river-valleys between Burmah and the mountains that join the western boundary of Cochin-China. Both rivers are navigable for a considerable distance, especially that of Siam, which bears the name of Maygue, and appears to arise in the mountains of Tibet, and falls into the Gulf of Siam. The river district, including Cambodia and Laos, is divided from Siam by a wide group of mountains running N. and S. It owes its fertility to the Maykung, a large river, also arising in Tibet, and running parallel to the Maygue. Both rivers are subject to periodic inundations, that give great fertility to the regions through which they pass. Laos is represented by Kæmpfer as a powerful state, protected from foreign enemies by deep forests and rugged mountains. It lies N. of Cambodia, with which it is conterminous. The valleys are fertile; the mountains produce gold and sapphires. Cambodia is chiefly known as producing the drug we term *gamboge*, which is probably the juice of a *Hebradendron*.

Eastern Asia.

Eastern Asia comprehends Cochin-China, Tunkin, and the Chinese empire.

Cochin, Tunkin.

Cochin-China or *Southern China* is a narrow mountainous tract, bounded on the E. by the ocean, on the W. by deserts and mountains, that separate it from Cambodia and Laos, and on the N. is divided by a small river from Tunkin, which it has lately partially conquered. It has many good harbours along its extensive coasts, of which Turon is

Asia.

the best known. Staunton represents the country as fertile and well cultivated, the people as industrious and civilized. They, as well as the Tunkinese, are of Chinese descent. Their coasts abound with the edible birds' nests, formed by a species of swallow. See COCHIN-CHINA and TUNKIN.

China. The vast empire of China presents an area computed at 1,297,999 square miles, according to Staunton, and a population of 333,000,000, being the most densely peopled region of the earth. Its enormous surface is much varied, producing the vegetable riches of every climate. Chinese Tartary is very mountainous; and chains of granite mountains traverse China in various directions; but the great chains generally run from W. to E., and send the principal rivers in that direction through fertile plains of enormous extent. The principal of these rivers are the Amur, in the north; the Hoan-ho, and Kian-ku in the central districts, both having a course of more than 2000 miles; and the Hon-kiang, and Pe-kian in the S. It is needless to state here what is discussed fully under CHINA.

Oceanic Asia. Oceanic Asia embraces all the Asiatic Isles properly so called; and some would also include under this head the distant New Zealand, and vast continent of Australia. We limit this division to Ceylon, the Andaman Isles, the Sumatran chain, including Java, &c., Borneo, Celebes, the Moluccas or Spice Islands, the Manillas or Philippines, Formosa, Lu-ku, Japan, Jesso, and Tchoma. For a particular account of this division, we refer to the different heads just enumerated.

Climate. Asia, extending from the equator to the Arctic Sea, necessarily possesses great variety of climate. But though here, as in every other country, the climate is regulated by the distance from the equator, this general law is modified by accidental causes, which it is curious to trace. In the wide extent of Asia great peculiarities of temperature occur, which cannot be very clearly explained. To such inquiries some uncertainty will always attach, and anomalies may appear of which we can offer no solution. Facts are our only sure guides; and to these, therefore, in the following observations, we shall endeavour to adhere.

The height of the land above the level of the sea is as sure a cause of cold as distance from the equator; and countries are not only cold in proportion to their height, but a mass of cold air is accumulated above them, which, being dispersed, is carried towards the equator, and extends the dominion of cold into the regions of heat. Land and water, also, are the causes either of heat or cold, according to their situation. The great mass of the ocean is little affected by the changes of the seasons; and it consequently preserves the medium temperature of the whole year. Hence the vicinity of the ocean cools the temperature of the equinoctial regions; and in higher latitudes it moderates the extremes both of heat and cold, being in winter of a higher temperature, and in summer of a lower temperature, than the superincumbent air. The surface of the earth, again, imbibes heat or cold much more readily than the ocean; and it is only at considerable depths that it is found to give the medium temperature of the year. The vicinity of land, therefore, in the polar countries, is the cause of cold, while in the southern regions of the equator it is an equally powerful cause of heat. Thus Africa, which extends so far to the S., and which contains a greater proportion of land within the tropics than any other division of the globe, is a vast store-house of heat, from which it is dispersed far and wide, and even reaches the shores of Europe in hot and parching winds; while, on the other hand, the breadth and extent of the American continent towards the N. sufficiently accounts for the coldness of its climate—the N.W. winds which sweep across its frozen wastes extending their inroads into the regions of heat as far sometimes as Mexico or Vera Cruz.[1] The influence of the ocean in moderating the severity of the winter is exemplified in the climate of Great Britain, where no such intense cold ever prevails as in corresponding latitudes on the continent of Europe, and more especially on that of Asia. The climate of a country is also affected by the direction of the winds; and hence the eastern shores of America, owing to the trade-winds, which blow from the E., and are cooled in their passage across the Atlantic, have not the same sultry heats as the opposite shores of Africa, where the same winds are heated to an intense degree in their passage over the burning deserts of the interior. The northern frontiers of Asia, and its prodigious elevation towards the centre, necessarily consign the greatest portion of it to the dominion of cold. Among the central mountains perpetual winter reigns; and from these snowy deserts the influence of cold is widely extended over the high plains of the interior. In Tibet, which is about the same latitude as Northern Africa or Arabia, namely, between the 30th and 35th degrees, there is a continuous and severe winter of three months, which is of such uniform severity that at its commencement the inhabitants kill their meat, and it is kept perfectly fresh for three months.[2] To the W., along the whole range of elevated country that extends into Persia and to the Caspian Sea, the climate is modified by the elevation of the ground. In the countries of Balk and Bokhara, which lie on the northern declivity of the great ridge of the Hindu Koh Mountains, in the same latitude as the S. of Europe, namely, the 39th and 40th degrees, and all along the banks of the Oxus, the climate is remarkably severe. For three months the winter is intensely cold, the wind being dry and piercing, and the snow lying deep on the ground. The rivers are all frozen over, and the Oxus during all that period is passable for caravans.[3] The summer, again, is equally hot. Persia, in like manner, being nearly in the same latitude as Arabia, the hottest part of the earth, and having an excessively hot summer, has in the northern and central parts the severe winter of a northern climate, with drifting snow, which lies deep on the ground for three months; and this is owing entirely to its elevation, which is estimated by Fraser to be 4000 feet above the Caspian Sea.[4] The lower valleys and exterior plains of Asia, which lie to the south of the Himalaya Mountains, including Arabia, the southern and flat parts of Persia, Hindustan, and India beyond the Ganges, constitute the tropical and warm regions of this continent, of which the climate, though it agrees in general with their position on the globe, still varies from local causes. Hindustan, for example, and India beyond the Ganges, though they approach nearer to the equator, are not nearly so hot as Arabia or the adjacent countries. The course of the seasons is also more constant; and it is here that we meet with those remarkable winds, the monsoons, which blow six months in opposite directions, from the S.W. and N.E., with some slight variations, and which extend their influence over all the countries

[1] See Humboldt's *Political Essay on the Kingdom of New Spain*. He mentions that at Vera Cruz the centigrade thermometer sometimes falls, owing to those northern blasts, to 0 or to 32 degrees of Fahrenheit; and that even at Mexico they sometimes, though rarely, bring down the thermometer to the freezing point.

[2] Turner's *Embassy to Thibet*, p. 217, 301, 356.

[3] Fraser's *Narrative of a Journey into Khorassan*, Appendix, p. 95.

[4] Kinneir's *Geographical Memoir of the Persian Empire*, p. 122. It is mentioned in the Journal of a Mr Campbell, quoted by Sir J. Malcolm, that while he was at Tabreez a heavy fall of snow occurred in May; and in December and January the thermometer at night was never above zero. (Sir J. Malcolm's *History of Persia*, vol. ii. p. 509.)

which lie between the mouth of the Indus and the Chinese Sea. The monsoons follow the course of the sun, and this fact points to the cause of the phenomenon. Heat and cold being the great agents which, by rarefying or condensing the air, disturb its equilibrium, and set the winds in motion, land, when it is heated by the solar rays, acts on the superincumbent air, and causes it to ascend, when it is immediately replaced by an irruption of cold air from the sea. Hence the regular sea-breeze which prevails in all the tropical islands during the day, and the opposite current from the land during the night; and this alternation of the sea and the land breezes, occasioned within 24 hours by the varying temperature of an island, is just an example of the effect that must be produced by a heated continent and by the change of the seasons. As the sun advances into the northern tropic, the land of Asia, Europe, and almost the whole of Africa, is heated by his influence; by which the air being rarefied, and rising aloft, a current of colder air rushes in from the sea. Accordingly it is found, that with the approach of summer, the plains of Hindustan, Burmah, and China, heated by the intense rays of a vertical sun, powerfully attract the cold air, which flows with a steady stream from the Southern Ocean, exactly in the tract of the heated continent, namely, from the S.W. to the N.E. When the sun passes into the southern hemisphere, the monsoon alters its course. Winter now reigns in the mountainous and northern parts of Asia, and the heat in the lower regions is not so great. The land, in place of heating, cools the air, which flows into the warm regions of the S. from the N.E. in the direction of the continent, as it formerly flowed towards the N. from the S.E. The S.W. monsoon sets in about the beginning of June in all the islands of the Indian Ocean, and traverses the southern plains, until it is turned towards the W. by the central mountains, and finally arrested in its progress. It is ushered in with the most tremendous thunder and lightning, with tempests of wind and floods of rain. This is the commencement of the periodical rains through all the tropical regions of Asia, which are at their height in July, and gradually abate about the end of September, departing amid thunders and tempests, as they came. Before the setting in of the monsoons there is a clear sky, with a hot parching wind, succeeded by sultry calms, under which all nature seems to droop. The rains effect a sudden and total change in the aspect of the country: the rivers are swollen, the air is pure and refreshing, the sky varied with clouds, and the earth covered with the most luxuriant verdure.[1] Such is the climate of Southern Asia, from China to the southern coast of Africa. But the peninsula of Arabia is not subject to the influence of the monsoons; and in place of the tropical rains, it has generally, in the mountainous parts, the winter and the spring rains.[2] The climate during summer is hotter than in any other part of the world, the thermometer frequently rising to 110°, and even, it is said, to 120°, in the coolest and shadiest parts, while dead calms prevail often without interruption for 50 or 60 days, and are succeeded, as the temperature begins to vary and the winds to resume their activity, by violent and hot blasts from the desert. The vicinity of Arabia to the African continent, by which it is sheltered from the cool breezes of the sea, while it receives the sultry air from its burning plains, is unquestionably the cause of its extraordinary heat; and it will be remarked that those violent heats extend eastward from Arabia exactly in the direction in which they are received into the lower valley of the Euphrates and the Tigris, where at Baghdad they raise the thermometer to 120° in the shade. It has been already mentioned that the progress of the monsoons to the N. is arrested by the central mountains; and the elevated tract of country, therefore, which lies to the N. of this barrier, namely, the kingdom of Kokaun, over which are spread the headwaters of the Oxus, Balk, the ancient Bactriana, Bokhara, and the countries W. of the Indus, as far as the Hellespont, depend on the spring and the winter rains which they receive from the W.[3]

Western Asia has been long celebrated for the mildness and serenity of its climate, which is hot and dry, though it is tempered by the cool breezes from the mountain tracts by which it is intersected. In the northern parts, along the coasts of the Black Sea, the country is liable to excessive rains; while the southern shores of the Mediterranean are exposed to the sultry simoom blasts from the African or Arabian deserts.

Northern Asia, of which the Altaï chain is the boundary, is the proper region of cold; and the severity of the climate is said to be aggravated by the vast expanse of the continent in the frozen latitudes of the N. In the interior of Asia the milder element of the ocean can have no influence on the rigour of perpetual winter; and from the Arctic Ocean to the Altaï Mountains the north wind sweeps without interruption along the Siberian plains, and occasions an intensity of cold which is not experienced in the corresponding latitudes of Europe. It is remarked by Malte-Brun, that the cold increases as we proceed eastward, to such a degree, that on the coasts of Mantchuria, in the same latitude as France, the winter commences in September. This intensity of cold he ascribes to several causes: *1st,* To vast mountains covered with glaciers, which rise between Corea and the countries on the river Amur; *2dly,* to the still greater mass of mountains which separates the Amur from the Lena; *3dly,* to the thick and cold fogs which constantly overhang those frozen countries, and intercept the rays of the sun; and, *4thly,* to the absolute want of inhabitants, and consequently of cultivation. This, however, is only true with regard to the extreme N.E. of Asia; but in the whole, such causes tend to the increase of cold. They are, however, counterbalanced by the influence of the Eastern and Arctic Oceans; and the average cold is consequently greater towards the centre of the continent than along its northern shores. The average cold of the winter in Nova Zembla, between N. Lat. 70. 30. and 73. 30., is −35° 30′ Celsius; its minimum was −39° 30′; but at Statust, in N. Lat. 55., near the Ural, it is as low as 44°, while the minimum was 46.° The greatest cold ever observed in Asia was at Nishneï Kolymsk on the Kolyma, in N. Lat. 68. 32., namely −50° 20′ on the 8th January 1821.

Vegetable productions.

Asia, from its vast extent and unequal surface, not only comprehends within its bounds the vegetable produce of the whole earth, from the low creeping lichen which flourishes on the borders of perpetual snow, to all the splendid varieties of tropical vegetation; but it presents these varieties within a very short compass. It would be inconsistent with the plan of the present article to describe in detail the animal and vegetable kingdoms of Asia. It may be therefore generally stated, that the great staples of agriculture, the alimentary plants on which man depends for his subsistence, are, in the tropical countries of Asia, rice, of which there are 27 varieties; maize, millet, and many varieties of a coarser grain called dourra; as well as other species of legumes not known in Europe. The cultivation of these nutritious grains is confined to the plains of Hindustan and the hot countries to the east. Rice or maize may be sometimes seen in Persia, or in the hot plains of Lower Syria; but agriculture in these countries generally depends on the

[2] Niebuhr, vol. ii. sect. 29.

[3] Fraser's *Narrative of a Journey into Khorassan,* Appendix, p. 95.

grain of a colder climate. Persia is accordingly famed for the most excellent wheat, which is the chief food, and for barley and millet. Oats are more rarely attempted in that climate. Throughout Syria and Asia Minor, as well as Arabia, wheat, rye, barley, beans, and other grains, are chiefly sown; and in Bokhara, and generally in all the countries that lie between the Oxus and the Caspian Sea, these and other grains, with a variety of leguminous plants, constitute the chief aliment of the inhabitants.[1] Between the 50th and 55th degrees, these grains may with care be raised all over Asia; but beyond this they cannot so well resist the severity of the climate. This is therefore the proper region of barley and oats, the cultivation of which may be extended to the 60th degree. Beyond this the powers of vegetation begin to fail; and the forests present dwarf trees with lichens, and some species of eatable wild berries, among which is the *Empetrum nigrum*. In ascending the Asiatic wild mountains, the same varieties of vegetable produce are observed as in receding from the equator, until, at the line of perpetual congelation, all traces of vegetation disappear. But the decrease of heat in proportion to the altitude varies in different situations, according as it is affected by local and accidental causes; and though the most accurate calculations have been made on the subject by Leslie, Humboldt, and others, they are modified by local causes. Thus the limits of perpetual congelation have been fixed by Humboldt at 15,700 feet under the equator, and 15,000 in the latitude of 20 degrees; yet Captain Webb, in his journeys among the Himalaya Mountains, observed, on the banks of the Sutledj river, which must have been at least in the 30th degree of N. Lat., the finest pastures, and crops of a species of barley from which the natives make their bread, at a height of 15,000 feet, the supposed line of perpetual frost. And at a pass among these mountains, in 30 degrees of N. Lat., plants were found that ripened their seed at the enormous height of 17,000 feet. In Lat. 30. 25. the same travellers saw fields at the height of 11,790 feet, not only without snow, but covered with extensive crops of buckwheat and Tartaric barley. The decrease of heat in proportion to the altitude attained appears to be affected in those climates by the transport of the warm moist air of the S.W. monsoons from the Indian Ocean. We cannot fix either the lower or the higher limit at which wheat and other European grains could be brought to maturity among the Asiatic mountains. It is evident that the decrease of heat as we rise above the level of the sea is modified by local causes, in the same manner as when we recede from the equator; and hence the same vegetable produce is not uniformly found at the same height, any more than within the same latitudes. It is possible that in the interior mass of the mountains the cold may be greater than among the exterior ridges, and that the European grain, and the other congenial produce of a cold climate, may not on this account ripen at so high an elevation. It is mentioned by Turner, that he saw wheat in Tibet in a green state, which he was assured would never ripen owing to the severity of the climate.

Of the other plants which minister to the comfort of man, and afford valuable articles of commerce, Asia possesses great variety. The tea plant, which is exported so largely to Europe, is indigenous to China, to which it is a source of prodigious wealth. It has more lately been found also in Assam, where it has been successfully cultivated by the British. Arabia is the native country of coffee, where it still arrives at its greatest perfection. The sugar-cane is cultivated in Hindustan, though not with the same energy and skill as in the West Indies; and also in some of the hottest parts of Asia Minor. Tobacco is very generally produced in Southern and Western Asia; and opium, the great intoxicating drug of the East, is an important article of cultivation in Hindustan. It is chiefly produced in Bengal, Bahar, and Malwah; and upwards of 4,000,000 pounds of opium were annually sent to China, before it was prohibited by the Chinese government. The vine grows to great perfection among the rocky heights of Palestine, and in the mountains of Syria, where wine of a good quality is made, and also in Arabia and Persia. Industry and skill are alone necessary to improve the advantages of nature, and to render this precious produce a valuable article of commerce. The cotton shrub, which yields so useful an article of clothing, has from time immemorial been cultivated in India, growing in Arabia, Persia, and throughout Asia Minor; and the mulberry which, by feeding the silkworm, affords so splendid an article of dress, is grown with success in Syria, Mesopotamia, and Armenia. Flax and hemp are common throughout both Southern and Western Asia, and they would grow also in Northern Asia if the inhabitants knew how to profit by the advantages of the country. Indigo is another important article, which is cultivated in India and in some parts of Syria, as well as in Arabia. The Asiatic islands have been long celebrated for various aromatic plants; and the juice which exudes from the trunks of the smaller trees is of the richest fragrance. Among the species of laurels which abound in the southern parts of India and Ceylon we find those which produce mace, cassia, and camphor; and, lastly, the cinnamon tree, formerly supposed to be a native of Arabia; also the clove and the nutmeg trees. The balm of Mecca is the finest of all the tribe, and diffuses an exquisite perfume. Arabia has been long celebrated for frankincense and myrrh. Asia furnishes also many plants used in medicine, as well as in dyeing, such as the castor-oil plant, the senna, the aloe, and others, which extend all over the southern parts and through Asia Minor.

In Southern Asia the forests abound with the most valuable trees, with the most durable woods, and with every variety of ornamental and dye-woods. The teak tree, which grows in the woods of India, surpasses all others in durability. There are many trees which minister to the wants and appetites of man. The sago palm yields from its stem and roots the well-known farinaceous substance which bears its name. The toddy palm yields a rich juice which, when fermented, becomes a strong spirituous liquor. The fan palm, which grows in some parts of India, is remarkable for the breadth of its leaves, one of which is sufficient to cover a dozen of men, and two or three to roof a cottage. The bread-fruit tree, which grows in India, yields a farinaceous fruit resembling bread prepared from grain. All the common fruit trees of Europe are also found in the hilly parts of India. Asia Minor and the banks of the Euphrates abound in the myrtle, the laurel, the turpentine, mastic, tamarind, cypress, sycamore, and other trees. The oriental plants are numerous in Persia; and in the Syrian mountains the oak and the cedar, celebrated in ancient times, grow to a great height. In the northern countries of Asia the trees most prevalent are the oak, the ash, and the elm; and still farther N. there is the dwarf birch and the mountain willow; also the pines and the firs, which rear their tall heads, and spread over the scenery their permanent hue of dark green. The strong and glutinous liquid which exudes from these northern trees is converted into tar, pitch, and turpentine, and becomes a valuable article of commerce, useful for many purposes.

All the most delicious fruits are raised in the tropical countries of Asia. Those most celebrated in India are the guava, the jambo, the mango, and the pine-apple: many others might be raised if garden-cultivation were carried to

[1] Fraser's *Narrative of a Journey into Khorassan*, Appendix, p. 96.

Asia.

the same perfection as in Europe. Syria, Palestine, the banks of the Euphrates, and Persia, are famous for the variety of their fruits, and produce abundantly pomegranates, oranges, lemons, almonds, peaches, figs, quinces, olives, walnuts, and melons of all sorts. In the neighbourhood of Damascus all the fruits of Europe arrive at maturity; and near the Caspian Sea there are whole forests of chestnut trees. The date tree, the fruit of which is in many parts the chief subsistence of the inhabitants, grows in Persia, Mesopotamia, Arabia, Syria, and Palestine. In the higher parts of these countries other fruits are to be found, namely, the apple, the pear, the cherry. In Northern Asia, horticulture is little practised; and, excepting wild berries, few other fruits are to be seen in its desert and inhospitable plains. Flowers of all sorts, in the most splendid profusion and variety, and of the richest fragrance, adorn the country in Southern and Western Asia, and give it the appearance of a flower-garden. On such a subject, however, which presents so wide a field of inquiry, we cannot enter into details, which would hardly prove satisfactory to the general reader, and still less to the man of science.

Animals.

The desolate tracts of thick jungle and dense forest which abound in Asia afford extensive cover for wild animals, which are accordingly found in great numbers, and comprise all the known *genera* of the globe. The lion is found in Persia, Mesopotamia, on the banks of the Tigris and Euphrates, and was formerly known in Asia Minor, but has now either entirely disappeared, or is rarely seen. It was at one time supposed that this formidable animal did not haunt the forests and jungles of India. But lions have been seen in great numbers in the N. of India, in Guzerat, and in the province of Delhi, to the N. of that place.[1] The tiger is a native of Asia, to which continent he exclusively belongs, having never migrated into the other regions of the globe. He is spread over all parts of Southern Asia, from the islands of the Indian Ocean, where he exists in amazing power and ferocity, to the great ridge of the Himalaya Mountains.[2] His progress northward is checked by the increasing cold; yet is he found in some of the higher regions, where ice is seen during the winter. It is certain, however, that he is a native of a hot climate; and it is probable, therefore, that when he feels the approach of winter, he retires from the cold of the high country into the warmer and lower valleys of the south. Tigers are seldom seen in the countries westward of the Indus, though they may occasionally stray from their native haunts along the W. of that river into the mountain tracts of Beluchistan.[3] The tiger is not found in Persia, Arabia, or in any part of Africa, though it is quite certain that the country is quite congenial to his constitution and habits, and that if he could once reach it he would quickly propagate his race through its deep forests. Yet the lion reigns supreme in the woods of Africa, while the tiger is the lord of the Asiatic jungles. It would be curious, if we had full materials for such a speculation, to trace the distinct regions of the globe which are occupied by the various animal and vegetable tribes. Plants, we know, are transported from the countries in which they are indigenous, and flourish in another soil and climate equally congenial; and, in like manner, the animals of one country have been transported with equal success to other countries, where they have multiplied. The wild and ferocious animals it is the object of man to destroy rather than to increase; and they would therefore receive no aid from him in their migrations from one region to another. Hence we find that those countries which are widely separated, and which present no practicable communication for animals, have each its own peculiar and distinct class. America has an entirely different race of animals from Africa or Asia; while the animals that are found in the islands or continent of Australasia resemble those of no other quarter of the world. The zoology of Asia and Africa, from their vicinity, and from the comparatively easy communication between them, does not present such diversities; yet it is remarkable, that while the lion is common over all Africa, the tiger has never yet been seen; while in Asia it is nearly the reverse, the tiger, and not the lion, being the more common of the two. There can be no reason, we should imagine, why the tiger should be confined to Asia, while there are other countries equally suited to his habits, except that, being indigenous in the regions of Eastern Asia, he has never been able to cross the barrier of mountains and deserts by which these regions are separated from Persia on the west. Beyond the western banks of the Indus the country is mountainous and impassable, and the climate extremely cold; the ridges from the Himalaya Mountains extending southward nearly to the sea, and the country beyond being merely a narrow strip of hot and sandy desert. Beyond this, farther to the W., extensive deserts are found destitute of water and of all traces of vegetation, which would as effectually oppose the passage of wild beasts as the trackless ocean which divides Africa and America, and leaves to each its own class of indigenous animals. The other wild animals of Southern Asia are leopards, hyenas, jackals, tiger-cats, wild boars, antelopes, elks, red and other deer, foxes, hares, mangooses, ferrets, porcupines, &c. All these are to be found in the southern plains of Asia. The hyenas, wolves, jackals, and bears, abound in some of the hilly tracts, and in the mountains of Beluchistan and the other countries to the west of the Indus. The first three make dreadful havock among the flocks. The same animals are found in Persia, Mesopotamia, in Asia Minor, and in Palestine: and it is said that the lion is occasionally seen on the banks of the Jordan. The ounce is a formidable animal in these countries and in Syria, and is sometimes mistaken for the tiger. The striped hyena is often to be met in the Persian forests.[4] The wild dog is common in Northern India, in Beluchistan, and in all the mountainous countries to the E. of Persia. It is a large and powerful animal, and extremely ferocious. They hunt in packs of 20 or 30, and frequently seize a bullock, which they kill in a few minutes.[5] The bones and remains of tigers, supposed to have been destroyed by the combined attack of these animals, are also sometimes found in the woods of Northern India.[6] The wild ass is a native of Persia, and is remarkably wild, and fleet in its movements. It is also common in the northern mountains of India, and in the countries to the west of the Indus. The hemionus or wild horse is found about the Sea of Aral. The wild sheep and the wild goat are common among the mountains.

Of the domestic animals, the elephant claims the preeminence, being unequalled by any other animal for the purposes of draught. This animal is confined to the southern countries of India, where the climate is hot, being seldom seen in the mountainous tracts towards the N. The camel is used for domestic purposes over a far wider extent of country than the elephant. This animal is of two species, the one with two humps, and the common camel with only one hump. The latter is the camel of Arabia, Syria, Persia,

[1] Elphinstone's *Account of Cabul*, p. 141.

[2] Bishop Heber.

[3] See Pottinger's admirable account of the countries of Beluchistan and Sinde, chap. vii. which is replete with interesting information. The journey of this officer and of Captain Christie, from India to Persia, through these wild tracts, inhabited by hordes of robbers, may be considered a most perilous and honourable achievement.

[4] Kinneir, *Memoir of the Persian Empire*, p. 42.

[5] Pottinger's *History of Beluchistan*, chap. vii.

[6] Bishop Heber.

India, and Northern Africa. A lighter variety of this species is the dromedary, used only for riding, and differs from the camel of burden as the racer does from the draught-horse. The two-humped camel is the Bactrian species, and is so rare, even in Western Asia and India, that Captain Lynch states, that in a caravan of 5000 camels, there were not above eight or ten of this Bactrian species. In Mongolia, however, they are very numerous. The dromedary is chiefly used for travelling, and its valuable quality is swiftness, by which, joined to its capacity of enduring hardship, it is qualified to travel at an incredible rate for many successive days. In all the low countries, especially in the dry and sandy tracts, such as Arabia, Syria, &c., the common camel is employed. The two-humped camel is a native of the high countries in the neighbourhood of the Oxus and the Jaxartes, where it is still chiefly used. So large a portion of Asia is occupied by vast plains and wastes of sand, that its interior intercourse must be maintained by land journeys. But without the aid of the camel, it would be impossible to traverse extensive deserts destitute both of food and water; and in those arid countries such an animal, which has been truly called the *ship* of the desert, is the most valuable gift which Providence could bestow.

The other domestic animals of Southern and Western Asia are horses, mules, asses, buffaloes, black cattle, sheep, goats, &c. Arabia may be considered the native country of the horse, in which he arrives at the highest perfection, and combines all the most estimable qualities of symmetry form, fineness of skin, fire, docility of temper, fleetness, and hardiness. It is chiefly from the Arabian breed that the horses in other parts of the world have been improved. In Persia the horses are neither so graceful nor so swift as those of Arabia, being high, with long legs, spare carcases, and large heads; but they are highly prized by the inhabitants for their extraordinary capacity of enduring fatigue. To the E. of Persia, at Herat, the breed of horses is fine; also on the banks of the Indus and its tributaries; and in the higher regions of Balk and Bokhara they are excellent and numerous, and are exported in great numbers to Hindustan.[1] The mule and the ass, all over India, are miserable animals. The mules are of better quality in the Punjaub, on the upper course of the Indus, and they improve still more further west. In the countries W. of the Indus, they are superior to those in Hindustan, and in Persia there is a still finer breed. But the mule of the East is inferior to that of Europe. The ass partakes of a similar improvement in his progress westward, and is a far finer animal in Western Asia than in Europe. In Syria, Palestine, and generally in Asia Minor, he is distinguished by agility, fire, and patience of fatigue, and ranks in the first class of domestic animals. Buffaloes are found in the hot plains of Asia, as well as in the mountainous tracts; and the oxen which are used in the plough have all a hump on their backs. The wealth of the pastoral tribes, who rove about in the western plains of Khorassan, and in the hilly tracts of Afghanistan, consists chiefly in sheep, which have tails a foot broad, and composed entirely of fat, but in other respects resemble the English sheep, being better and handsomer than those of India.[2] Goats are common all over Asia, especially in the mountains, where there are some breeds with curiously-twisted horns; and they are by no means scarce in the plains.

In the northern parts of Asia, and in the high mountain tracts, a different class of animals is to be found. These cold regions are not distinguished by the same profusion of animal life as the tropical countries. The beasts of the forest decrease in numbers, size, and fierceness; and the wolf, the bear, the glutton, and the wild boar, are the only ferocious animals which thrive in these northern climates. In advancing on the desolate plains of Siberia to about the 60th degree of N. Lat., we find the cold still taking effect on the animal as on the vegetable creation, and the living creatures, as well as the plants and trees, stunted in their full proportions. Beyond this limit a different order of animals appears, protected against the severity of the climate by a thick covering of fur, which is sought after as a rich article of dress in more opulent countries. These animals are accordingly hunted for their skins, which constitute the great staple article of trade in Northern Asia. In the Arctic regions the bear seems to form the only exception to the diminished grandeur of the animal creation. This animal, nourished in the regions of Northern Asia, acquires a larger size, and far greater power and fierceness, than in southern climates. The domestic animals of the northern and mountainous countries of Asia are of a less imposing appearance, and not nearly of the same strength as those in the lower valleys of the S. and W. In the high and cold plains of Central Asia the camel is no longer used as a beast of burden, nor in the northern parts of the continent. Tibet and Central Asia, till beyond the Altaï Mountains, are inhabited by Mongolish and Turkish tribes, whose wealth consists in their cattle, which not only furnish them with food, clothing, and shelter, but are also used as beasts of burden, and in the labours of agriculture. The yak of Tartary, or the bushy-tailed bull of Tibet, seems to supply the place of the camel in these mountainous countries. This animal is about the size of a small bull, of great strength, and is reckoned a valuable property among the itinerant hordes of Tartars, to whom it affords the means of easy conveyance, of clothing, and shelter for their tents, from the prodigious quantity of long flowing glossy hair on its tail, and finally of subsistence from its milk and flesh. In those mountains is also found the musk-deer, which delights in the most intense cold, and of which the musk, a secretion by the male, affords a revenue to the government, as well as a valuable article of trade. Here, also, on the highest mountains, amid ice and snow, is the Cashmere goat, the wool of which affords the materials of the finest shawls.[3] Wild horses are seen in the high plains of Tibet; and the breed of sheep, a peculiar species of which is indigenous to the climate, is of great value. They are nourished on the short and dry herbage of these exposed plains, and serve for subsistence to the inhabitants, as well as for beasts of burden. The wild and extensive plains of Tartary are inhabited by pastoral tribes, who depend in like manner on their herds. On the southern side of the Altaï Mountains we find the same tribes of wanderers, most of them the scattered remnants of the Tartar nations who had formerly so deep a share in the great revolutions of Asia. All these tribes subsist chiefly by pasturage. Near the Ural mountains some live chiefly by hunting or ensnaring the elk and other wild animals for their furs. Among those who are shepherds sheep and horned cattle are found; while the hunting tribes have scarcely any domestic animals. In all these countries the wolf and the bear are known to abound. In the rigorous climate, farther to the N., where the cattle are stunted in size, and can scarcely subsist, their place is supplied by the reindeer, a species peculiar to a rigorous climate, and most valuable for all domestic purposes, whether for draught or for subsistence. During part of the year the inhabitants of those desolate countries subsist upon its flesh or milk, its skin furnishes them with the chief part of their dress, and its horns with such domestic utensils as they require. The dog is also trained to draw the sledge.

The feathered race in Asia includes almost every known species. In the southern parts are found all the tropical

Asia.

birds, distinguished by the most beautiful plumage, and some of them uttering sounds that have a resemblance to the human voice. Here are also found some of the largest and rarest birds,—the ostrich, the cassowary, and, in the Himalaya Mountains, the gypaëte, one of which, shot by a British officer, is stated by Bishop Heber to have measured from the extremity of one wing to another the enormous length of 14 feet. The other birds are eagles, kites, vultures, magpies in the higher countries, hawks, crows, wild geese and ducks, flamingos, herons, bustards, florikens, rock pigeons, lapwings, storks, plovers, snipes, quails, partridges, different species of *fringillidæ*, and almost all the other small birds to be found in similar climates. In Northern Asia the feathered creation is nearly the same as in Europe.

The principle of life, which is so active throughout the torrid zone, and produces quadrupeds of the most enormous size, is also visible in the magnitude and numbers of the reptile tribe, many of them armed with the most fatal poisons, all of them odious to the sight, and some, such as the Python Bivittatus, attaining the length of 20 feet, and of such prodigious muscular strength as to coil round and crush large animals to death. The influence of cold is adverse to the growth of large serpents, which are not found in Asia to the N. of the Altaï Mountains. The shark, which is found in all warm climates, haunts the tropical seas of Asia; and the crocodile, which is a different animal from the alligator of America, though equally powerful and ferocious, infests the rivers. Innumerable insects of every form, and most of them noxious and destructive, swarm in the torrid regions of this continent. During the short summers of Northern Asia, the musquito and other insects abound in the woody tracts of Siberia, insomuch that near the Ural Mountains the peasants burn constant fires before their cottages, as a defence against their attacks.[1] But the locust, which is common in certain parts of Asia, is the most mischievous of all these winged creatures. They light upon a country in a cloud which darkens the air, and leave nothing green behind them; fields sown with grain being utterly laid waste, and trees stript of their leaves, and of all power to ripen their fruits. They overspread the country with an appearance of blackness for many miles; and when they are driven by the winds into the sea, their dead bodies cover the shore in heaps. These destructive animals appear occasionally in the countries to the N. and W. of the Indus, in Beluchistan, in the desert tracts of Khorassan, and in Persia.[2] They are sometimes seen in Arabia in countless swarms; and frequently to the north of the Altai Mountains, at the sources of the Irtisch, whence they extend their destructive flight as far as the Crimea and the southern provinces of the Russian empire.[3]

Historical sketch of the Asiatic nations.

Asia has been subject to more awful revolutions than any other part of the world. Though it was at a very early period the seat of flourishing kingdoms, it was soon desolated by war. Its wealthy cities, sacked by their conquerors, fell into decay and ruin; and many of its countries, once civilized and populous, now languish in desolation from violence and misrule. The mighty revolutions which have shaken this continent form an interesting subject, on which volumes might be filled. All that we can propose is a historical sketch of the great leading events which distinguish the annals of Asia, with a brief notice of the various nations which have flourished, or are now to be found within its limits.

Nineveh; Babylon.

The early history of Asia, like that of all other countries, is lost in antiquity; and the obscurity is but slightly dissipated by the indistinct accounts which we receive from the Greek historians, and the brief notices in the Sacred Scriptures, of the Assyrian and Babylonian empires. According to the account of Ktesias, the Greek physician of Artaxerxes Mnemon, the Assyrian empire was founded by Ninus, about 2182 years before our era, and lasted during 13 centuries. Ninus is considered as the founder of Nineveh, and is said to have extended his dominion over all the regions between Bactria and Egypt. He was succeeded by his wife Semiramis, who is stated to have been the founder or enlarger of Babylon, and to have extended her conquests as far as India. To her succeeded her son Ninyas, after whom follow a long succession of more obscure sovereigns, whose very names, except in as far as they may yet be recovered by the recent discoveries at Nineveh, and of the key to the arrowheaded character, may be said to have perished. The last of the series was that Sardanapalus who immolated himself when his capital was taken by his revolted subjects, Arbaces governor of Media, and Belesis viceroy of Babylon, about 800 years before the Christian era. It seems proved, however, that notwithstanding this alleged termination of this empire, the Assyrians of Nineveh continued to possess considerable dominions for two centuries later; and in fact it was only in the eighth and seventh centuries B.C., that the monarchy attained to a very high degree of power under the kings whom the Hebrew Scriptures call Pul, Tiglath-pileser, Shalmaneser, Sennacherib, and Esarhaddon, who extended their empire over Syria, and destroyed the kingdom of Israel. But their power rapidly declined; and Nineveh was finally destroyed by the united Medes and Babylonians, about 606 years B.C.

In the Sacred Scriptures we read of Nimrod, "the mighty hunter," "the beginning of whose kingdom was Babel." But nothing more is said of him; and all the early history of Babel or Babylon is very uncertain. All that we know is, that it was the seat of a kingdom in the year 747 B.C.: for its ruler Nabonassar established a chronological era, commencing in that year; but we know not whether he was an independent sovereign, or a tributary prince under the empire of Nineveh. In the following century, however, the kingdom of Babylon was raised to a high pitch of grandeur by several able princes, who extended their dominion to the shores of the Mediterranean. Of these, the most powerful was Nebuchadnezzar, who overturned the kingdom of Judah, destroyed Jerusalem, and carried away the principal inhabitants captive to Babylon, about 600 years B.C. He so greatly embellished that city as to consider himself as its second founder: but its glories were ephemeral; for in a few years after his death, it was besieged and taken by the Medes and Persians under Cyrus; from which time it ceased to be the capital of an independent state.

The ancient Medes seem to have been a branch of the great Indo-European family of nations; but their early history is utterly unknown, except in as far as it may have been interwoven with that of the Persians; by whose annalists both are represented as having been the inhabitants of Iran, under the empire of Jemshid. Media afterwards seems to have fallen under the dominion of the Assyrian monarchs; but, according to Ktesias and others, its governor Arbaces revolted against his sovereign, and established an independent kingdom. The history of that revolution, however, is so obscure, that some authors have considered Arbaces as not merely founding a new kingdom for himself in Media, but as supplanting Sardanapalus on the Assyrian throne at Nineveh. However that may be, it is pretty certain that, within two centuries after the time of Arbaces, Media was still subject to the kings of Nineveh.

According to Herodotus, the Medes lived long in a state

Asia.

of anarchy, till, tired of its evils, they chose for their king Deioces, a person who had acquired a great reputation among them for his just arbitration of their differences. Deioces built a fortified palace at Ecbatana, and established himself in the sovereign power of Media, which he transmitted to his descendants. His son and successor, Phraortes, engaging in a war with the Assyrians of Nineveh, was defeated and slain on the plain of Rogau. He was succeeded by his son Cyaxares, in whose reign the Scythians burst into the S.W. of Asia, and retained possession of Media for 28 years. On their expulsion, Cyaxares attacked the Assyrians; and, assisted by the king of Babylon, took and destroyed Nineveh, about 606 years B.C. He was succeeded by his son Astyages, in consequence of whose defeat by Cyrus, the empire was transferred from the Medes to the Persians, about 546 years B.C.

The Persians, like the Medes, appear to be a branch of the Indo-European family. Their early legends describe as their original seat a delightful country, enjoying a very mild climate, with seven months of summer weather. But Arimanes, the Genius of Evil, smote it with the plague of *cold*, so that it came to have ten months of winter, and only two of summer. In consequence, the people were compelled to seek other settlements, and, under the guidance of their sovereign or patriarchal leader, Jemshid, gradually found their way to the several fertile regions interspersed among the deserts that still cover a large portion of Persia. Their original country, of which Arimanes thus deprived them, is supposed by some to be the modern Turkistan; while others look for it in the opposite direction, in the modern Azerbijan. In the lapse of time the Persians were found occupying Persis, *Fars*, and also spread over the hilly and barren country extending towards the Indus and the Caspian. They seem to have been divided into many tribes, no less distinguished by their mode of life, than by diversity of rank. Three of them were considered as noble; and of these the Pasargadæ were the most illustrious. Of that noblest tribe, the most noble family was the Achæmenian; and to that family belonged Cyrus the founder, and Darius the establisher of the Persian empire.

Persia continued to rule over Asia for above 200 years, when its power was overthrown by Alexander the Great. His extensive conquests were divided among his generals, who renewed the strife for dominion which had been for a time extinguished by the ascendancy of Persia. Amid these contentions Parthia and Bactriana in the east rose to the rank of independent states. The Roman armies entered Asia about 200 years before the Christian era, and subduing all opposition, they finally established the dominion of Rome from the Hellespont to the eastern boundary of the Euphrates. By the decided triumph of this great power mankind obtained a fresh respite from the calamities of war. It was the first care of the Romans to cement by policy what they had gained by arms, and to establish order and tranquillity in all parts of their widely-extended territories. From this period, accordingly, may be dated the commencement of that brilliant era of prosperity and repose enjoyed by this portion of Western Asia for nearly 700 years, the time which elapsed from its final conquest by the Roman armies under Pompey to its subjugation by the Saracens in the 638th year of the Christian era. The people, profiting by the singular felicity of their lot, devoted their attention to commerce and the arts of peace, and attained to a high degree of wealth and refinement. All the civil institutions of society flourished; science and literature were cultivated; and mankind, basking in the sunshine of domestic repose, seemed to enjoy the illusion of perfect happiness. It is estimated that 500 populous cities covered the face of the country. These were adorned with magnificent temples and other splendid monuments of art; and some of them, such as Pergamus, Smyrna, Ephesus, &c., and especially Antioch and Alexandria, rivalled in extent and magnificence the majesty of Rome itself.[1]

Hindustan and China.

After an interval of 500 years, the Persian monarchy was revived under the dynasty of the Sassanides.[2] In Eastern Asia the splendid and populous empires of Hindustan and China, though imperfectly known in Europe, had flourished for many centuries. The origin of the Hindu power is buried in a remote antiquity. The first authentic notice of this truly remarkable people was brought to Europe by the officers who accompanied Alexander's expedition to India. Prior to the era of the Mahometan conquest, in the year 1000, the Hindus possess very imperfect materials for their history.[3] Hindustan comprehended then, as now, the extensive country bounded by the Indus on the W. and the Ganges on the E., though we know but little of its boundaries or internal state. The origin of the Chinese, as of other nations, is hid in obscurity. They claim their descent from a very high antiquity, their history going back by tradition to the remote period of 40 centuries, and for 2000 years their annals are verified by the testimony of contemporary historians. It is quite certain, indeed, that long before the Christian era they had emerged from the barbarism of pastoral life, and were devoted to agriculture and commerce; that they had acquired wealth and prosperity, and were thoroughly instructed in all the arts and refinements of civilized nations, as then known.

The pastoral tribes.

The historical sketch which we have given above includes only the civilized portion of Asia. But a great proportion of her population were in ancient times shepherds, who dwelt in tents; and it is the more necessary to attend to the distinction between these two classes, as it will be found to illustrate the political history of Asia, and those stupendous revolutions which have not only shaken this continent to its centre, but have been extended to the remotest parts of the world.

It has been already mentioned, that the vast table-lands of Central Asia, though containing large tracts of desert, are nevertheless interspersed with fertile and well-watered valleys, which produce abundance of pasture; and the immense plains to the N. of the Altaï Mountains, which extend over the whole breadth of the continent, from the Aldan Mountains E. of the Lena to the Urals, afford subsistence for innumerable herds of cattle. In all ages, accordingly, those plains have been inhabited by wandering tribes of shepherds, rude, ferocious, and delighting in war. It is finely observed by the Roman historian, that "the pastoral manners, which have been adorned with the fairest attributes of peace and innocence, are much better adapted to the fierce and cruel habits of a military life." Such, accordingly, has been the character of all the pastoral nations. They have been always addicted to violence and plunder; and their predatory expeditions, whether for the plunder of individuals or of empires, have been invariably conducted with the same fierceness and cruelty. In a pastoral state every man is a soldier, and he is trained to war by his daily occupations. He is hardened in his body by continual exercise and exposure to the weather; in hunting the wild animals of the forest, he acquires skill in horsemanship and in the use of all war like weapons; and in the perpetual migrations of his tribe, which must be carried on with the same order as the march of an army, he is trained to vigilance and discipline. These wandering barbarians were, besides, engaged, as may be easily supposed, in continual wars with each other. Here,

[1] Gibbon's *Decline and Fall of the Roman Empire*, chap. ii.

[2] Sir J. Malcolm's *History of Persia*, chap. iv.

[3] Rennel's *Memoir of a Map of Hindostan*.

as elsewhere, the usual scarcity of subsistence and of room would soon be experienced with the progress of population. Disputes would thence arise, and fierce contests, which would only terminate with the destruction of one or other of the contending tribes. Of such obscure wars we have no accurate account, though it is certain, that from time immemorial the work of mutual slaughter has been going on in the interior of Asia; and it is obvious that those vast multitudes, if they had been united under some able leader, who could compose or crush all domestic dissensions, might, in place of wasting their strength in intestine strife, have directed it against the civilized portion of the earth, where wealth presented a tempting prize to barbarian cupidity; and, accordingly, this was precisely the calamity by which mankind were at length overtaken. The world was to be disturbed by a conflict, not as heretofore between improved states, but between barbarism and refinement. The question was now to be decided, whether polished nations or barbarians should rule the world; whether literature, science, the arts, the improved institutions, and the whole order of civilized society, should be broken up and buried under an overrunning flood of savage hostility. From the earliest times the countries of Asia Minor, and some parts of Europe, were subjected to the irruptions of barbarians; but no permanent conquest was ever attempted, and the invaders were in general quickly repelled. Asia Minor was defended against the inroads of the Scythians by the Persian monarch; and Rome, in the lion-like vigour of her growing strength, quickly shook off such unequal adversaries. Whether, however, from the increasing population of the Asiatic plains, or from the greater political union of the different tribes, those attacks were renewed with more vigour than ever; and at times the mighty mass of population over the whole breadth of the continent seemed to be agitated by one movement; and, according as the impulse given was to the E. or to the W., the kingdoms of Europe or the empires of Hindustan and China were swept by the tempest of invasion. Those formidable expeditions were attended with various results. In those states which were vigorously ruled, the discipline and tactics of civilized warriors proved an overmatch for the untutored valour of barbarians. But, on the other hand, when the people, enervated by ease and luxury, neglected the study of war, and trusted for safety to a mercenary force, the country was overwhelmed by its barbarian conquerors. The Chinese empire was overturned about 200 years before the Christian era, by an irruption of the Huns; the fertile countries on the banks of the Oxus, and of the Jaxartes as far as the Caspian Sea, which had attained to wealth and prosperity under the Macedonian kings, and had ever since been cultivated like a garden, were reduced by the white Huns, and under their sway Kharisme, Bokhara, and Samarcand became the seats of industry and of flourishing manufactures, and the great marts of the Indian and European commerce; while the Roman territory in the W. was repeatedly assailed, and finally overturned, by hosts of barbarians, who had quitted the crowded plains of Asia in quest of settlements to be won at the point of the sword.

Mahometan power.

It was about the middle of the seventh century that the Mahometan power emerged from the Arabian deserts; and the shepherds of those burning plains, inflamed by religious enthusiasm and the love of plunder, were equally formidable in war with their brethren of the north. Of all the invaders who, in this unhappy period, desolated the world, the Arabian tribes were the most fierce and cruel. Their religion enjoined the blindest intolerance; they were commanded to propagate their faith by the sword; and it was accounted a merit in a true believer to shed torrents of infidel blood. The track of Mahometan invasion was accordingly marked by the ruin of peaceful cities and by unsparing slaughter. In the course of two years the plain and valley of Syria was subdued by the Arabs or Saracens, whose conquests were soon extended over Asia Minor in the W. and Persia in the E.; and the country of Transoxiana, or the fertile plains lying on the Oxus and the Jaxartes, were, after several severe battles, reduced under the power of the khalifs, whose authority, a century after the flight of Mahomet from Mecca, in the year 622, extended in Asia about 200 days' journey from E. to W., from the confines of Tartary and India to the shores of the Hellespont, and in Europe and Africa as far W. as the Atlantic Ocean.

The dominions of the Arabian princes, in their widest extent, were divided into provinces, under subordinate governors, who owned themselves the servants or slaves of the khalif at Baghdad, their temporal as well as spiritual ruler. In the decay of the supreme power, those rulers, under the forms of the most abject submission, had acquired independence; and the khalif remained at Baghdad the vain object of outward homage, while he was inwardly despised. The Persian kingdom was also detached from their dominion, being usurped by a new dynasty, and was extended from the Caspian Sea to the ocean. This dynasty, as usually happens in disorderly times, was supplanted by two families, who, making a division of the kingdom, ruled, the one over Khorassan, Seistan, the high plains of Balk on the northern side of the great Himalaya ridge, and the countries of Transoxiana, with the cities of Bokhara and Samarcand; and the other over the southern provinces of Persia, as far as the Persian Gulf, namely, Irak, Fars, Kerman, Khusistan, and Laristan. These families appear to have ruled in Persia for 125 years, namely, from 874 to 999. They were overthrown by the Turkish princes of the line of the Ghuznevides, the founder of which was Subuctageen or Sebectagi, who, from a common soldier, rose to the rank of a petty prince, and fixed his residence at Ghuzni. His dominions consisted chiefly of the tract of country which, after the division of Alexander's empire, composed the kingdom of Bactria, namely, the countries lying between the Caspian Sea and the Indus, and near the source of the Oxus. He invaded Hindustan, subdued Northern India and the province of the Punjaub, and rendered the princes of the countries tributary to the princes of Ghuzni.[1] His son Mahmoud of Ghuzni, who reigned in Persia about 1000 years after the birth of Christ, was still more famous for the extent of his conquests. He had extended his empire northward by the reduction of Bokhara; and he now determined, in the true spirit of Mahometan intolerance, to wage a holy war against the idolaters of Hindustan. At this period the Mahometans had effected no permanent settlement in Hindustan. The people were purely Hindu, without any admixture of foreign manners; and the whole country along the E. side of the Indus to Cashmere was ruled by a prince of the Brahmin race, and between whom and the kings of Delhi, Ajmere, Canoge, and Callinger, a confederacy was now formed against the common enemy of their country and religion.[2] Mahmoud entered Hindustan in A.D. 1000, and having defeated the armies of the confederate kings, he reduced the province of Moultan. Eight years afterwards he penetrated into the heart of India, where his farther progress was opposed by the confederated princes of the country, from the Ganges westward to the Neerbuddah. But the fanatical invader was still victorious, and his progress was signalized by rapine and slaughter. The idols were all broken to

[1] Sir J. Malcolm's *History of Persia*, chap. vii.

[2] See *Memoir of a Map of Hindostan*, xliv. Major Rennel's elaborate and masterly researches have thrown great light on the geography of this interesting portion of Asia.

Asia.

pieces, the temples, many of them of the most beautiful architecture, were pulled down, and an immense spoil was carried away. In the course of his twelve expeditions into India Mahmoud extended his conquests to the Ganges; and when he died, in 1028, his territories were of great extent. The annals of those disorderly times afford no very accurate data for ascertaining their exact limits, which are variously stated by writers of great authority. According to Major Rennel, the empire which he established comprehended the eastern, and by much the largest part of Persia, and extended nominally from the upper and western course of the Ganges to the peninsula of Guzerat, and from the Indus to the mountains of Ajmere in Northern India.[1] Sir J. Malcolm assigns Georgia and Baghdad for its limits on the W. and S.W.; Bokhara and Cashgar on the N. and N.E.; and Bengal and the Deccan, as far as the Indian Ocean, to the E. and S.E. But though a large portion of Hindustan was at this time overrun by the Mahometan armies, it was only the Punjaub, or the country of the Five Rivers, that was entirely reduced under any regular government, the other parts of the country being merely occupied by troops.

Turkish tribes.

The empire of Mahmoud declined after his death, owing to divisions and civil wars, but chiefly to the rise of the great Turkish tribe of the Seljookee, which was so called from the name of their renowned chief Seljook, who, being banished by his khan or chief from Turkistan, passed the Jaxartes with his numerous followers, and settled in the plains of Bokhara, in the neighbourhood of Samarcand, where he embraced the Mahometan religion. It is only when those barbarous hordes emerge from the desert, and come into contact with civilized life, that we obtain any clear account of their migrations and history. Their contests with each other, and their obscure wanderings in the interior, are not chronicled among themselves, and are seldom known to other nations. Hence we have rarely any clear data for tracing their origin, or their early conquests, or the consolidation of many tribes into one great nation. It is certain, however, that the vast population of Asia, agitated by internal tempests, has been always violently driven on the great empires of China and Hindustan, or on those of Persia and Rome, and has either made a breach, or, if repelled, has assailed the civilized world at some other more vulnerable point. China has been in all ages an object of attack; and it is generally believed that the Turks, and especially that tribe of them under Seljook, had been driven by the Chinese and a tribe of Tartars from the high plains of Asia, a short time before they sought refuge in the provinces of Transoxiana. They were living near the territories of Bokhara when they first attracted the notice of the Sultan Mahmoud, the founder of the dynasty of the Ghuznevides, who had advanced into Bokhara with his army, and was so impressed with the fine military qualities of their chief, the son of Seljook, that he induced them to cross the Oxus and to occupy the country of Khorassan.[2] He had soon reason to repent of this fatal error. Like all those wandering hordes, the Turkomans were shepherds or robbers. They either molested the neighbouring states by petty inroads, or, with the whole united force of the nation, they practised robbery on the great scale, seizing on kingdoms and despoiling nations. The first migration of these eastern Turkomans is generally fixed in the tenth century. They became formidable to Mahmoud, and more especially to his successor Massoud, who, from inability to resist their progress, was forced to grant them lands. He was afterwards defeated by them in a general battle; and the victorious Turks, under their leader Togrul Beg, whom they had now elected king, invaded Khorassan, and finally expelled the Ghuznevides, the descendants of Mahmoud, from the eastern provinces of Persia. They fled eastward towards the Indus, and established the Ghuznian empire in the north-western provinces of India. This empire was maintained with various success till about the year 1184, under the Ghuznian emperors.[3] It is difficult to give any accurate view of its limits, which in such turbulent times would naturally vary with the fortune of war. They appear to have embraced the eastern parts of Persia, the mountain country of Kabul or Afghanistan, and the Indian provinces of Lahore and Moultan. The Ghuznian dynasty was superseded by that of the Afghan or the Patan emperors, who completed the conquest of the greatest part of Hindustan Proper about the year 1210. Togrul Beg hastened to improve his victory over the Persian monarch. Turning his arms to the W., he invaded Irak, in the centre of Persia, and advancing westward of the Caspian Sea into Azerbijan, the ancient Media, he made his first approaches to the confines of the Roman empire. He afterwards proceeded to Baghdad, and by his conquest of that place gained possession of the person of the khalif, who was treated with the most profound veneration. His successors Alp Arslan and Malek Shah extended the empire transmitted to them by Togrul Beg. They subdued the fairest portion of Asia. Jerusalem and the Holy Land, which flourished under the mild sway of the khalifs, was taken and pillaged by one of the lieutenants of Malek Shah; and it was the vexation and rapine to which the Christian pilgrims were exposed in their journey to Jerusalem under the barbarous rule of the house of Seljook, that inflamed the indignation of the Christian powers, and gave rise to those wild and warlike expeditions for the recovery of the Holy Land, known under the name of the Crusades. The empire of the Seljookian Turks extended, under Malek Shah, from Egypt and Syria to Bokhara, which he conquered as far as Samarcand and Kharisme. He received homage from the tribes beyond the Jaxartes, and compelled the sovereign of Cashgar to offer up public prayers for his prosperity, to strike money in his name, and to pay him an annual tribute.[4]

Asia. A.D. 1037.

Internal wars.

From this period till the invasion of Zinghis or Ghenghis Khan, which is 110 years, namely, from 1092 to 1202, Asia was convulsed by foreign and intestine wars. The death of Malek Shah dissolved the unity of his extensive empire, in which three new dynasties arose; while in many cases the provincial governors contended for supreme authority, and harassed the country by their mutual wars. It was during this era of division and weakness that Asia Minor, which was ruled by the dynasties of Iconium and Aleppo, was invaded by the hosts of the European crusaders, who rapidly subdued the country, took the holy city of Jerusalem, and extending their conquests over the hills of Armenia and the plains of Mesopotamia, founded the first principality of the Franks or Latins, which subsisted 54 years, beyond the Euphrates. Those European invaders retained possession of Asia Minor and of Syria for nearly 200 years. Exhausted at length by a long series of sanguinary wars, and not receiving reinforcements from home, they were finally driven from all their conquests by the coalition of the Turkish powers.

The Turkish dynasty of the Seljooks continued for 158 years, or 215 years if we reckon from the time that the tribe first emerged from the desert under its leader Seljook. The sultan of Carisme or Kharisme, who ruled over the country

Asia.

situated between the Oxus and the Jaxartes[1] with delegated authority, profiting by the distractions of the neighbouring kingdoms, declared himself independent, and invading Persia with a powerful force, he defeated and slew the last of the Seljookian monarchs, and subdued the greater portion of their dominions. He extended his inroads over Syria, and had become the terror of the Ayoubite princes and the sultans of Iconium; and he finally established his wide dominions from the Persian Gulf to the borders of India and Turkistan.[2]

Zinghis Khan.

The continued irruptions of those barbarous tribes into the regions of civilization had given rise to scenes of calamity and of revolution hitherto unequalled in the history of the world. Conquests had no doubt been achieved before by the warlike nations of antiquity, and the rage of war had been satiated by the ruin of peaceful cities and the massacre of the people. But these evils, great as they were, fell far short of those inflicted on mankind by the conquests of the pastoral tribes, which were carried to such a height by Zinghis Khan and his destroying bands, as nearly to threaten the desolation of the earth, and the extinction of all the arts, improvements, and civil institutions of society. This Tartar chief, or savage, who was originally the khan of a horde of shepherds, comprising 30,000 or 40,000 families, inhabiting the countries to the N. of China, seems, about the beginning of the thirteenth century, to have united under his sway all the other tribes which, under the various designations of Huns, Turks, Moguls, or Tartars, wander on the spacious high lands and plains of Asia, between China, Siberia, and the Caspian Sea. He became, to use the expressive language of the great historian of Rome, "the monarch of the pastoral world, the lord of many millions of shepherds and soldiers, who felt their united strength, and were impatient to rush on the mild and wealthy climates of the S." This great conqueror swept over the whole breadth of the earth with his barbarian hordes. Art and nature were found alike unequal to stay his destructive course. He traversed mountains and rivers, barren deserts and unhealthy climates, with resistless speed; and he oppressed the walled towns by his countless multitudes. The Chinese were the first enemies with whom, after quitting the desert, he measured his strength. His innumerable squadrons penetrated at all points the feeble rampart of the great wall. Ninety-six cities were plundered and destroyed, and the smaller towns and villages were reduced to ashes; the aged were given up to the destroying sword; a prodigious multitude of children were carried away, who were afterwards massacred in the march homeward; besides a rich spoil in gold, silver, silk, and cattle.[3] In a second expedition he was equally successful; the emperor fled before his enemies to a more southern residence; Yenking or Peking was taken and burnt; and, through the weakness and division of the Chinese councils, the five northern provinces of the empire were reduced under the dominion of the Moguls.[4] The invincible arms of Zinghis were now turned against the sultan of Kharisme, who, as has been already mentioned, ruled over the fertile countries situated between the Oxus and the Jaxartes, and had extended his conquests over a great part of Persia. At this period his territories contained the flourishing and commercial cities of Samarcand, Bokhara, Kharisme, Herat, Balk, &c. His troops were overpowered in a bloody conflict with the Tartar host, the country was subdued, and the rights of conquest were as usual most savagely abused. The open country was desolated, the rich cities plundered, and the inhabitants either slaughtered or carried into captivity; and in some cases everything that had life, with the city itself, was destroyed. The cities that perished in this general ruin were, Bokhara, situated on a branch of the Jaxartes, a populous city, the centre of an extensive commerce, and the seat of science and religion; Otrar; Cojend, on the Oxus; Samarcand, situated near the source of the same river as Bokhara; Kharisme, where 100,000 men were massacred, and the surviving population reduced to slavery; Balk, to the S. of the Upper Oxus, which contained 200 splendid mosques, and a numerous population; Nisabaur; Herat, in Khorassan; Candahar, farther E.; besides numerous other smaller towns and villages. All that tract of country which extends from the Caspian Sea to the Indus, comprehending the ancient territories of Transoxiana, Kharisme, and Khorassan, and which was fertile, populous, and well cultivated, was entirely ruined by this irruption of the Tartars, so that, to use the words of the historian of Rome, "five centuries have not been sufficient to repair the ravages of four years." The conquests of Zinghis, before his death, extended W. from the Indus to the Euxine, from the Pacific Ocean to the Volga, and from the Persian Gulf to the confines of Siberia. A.D. 1227.

The children of Zinghis, who succeeded him, completed the career of conquest which he had begun. China, divided at that time into the two dynasties or empires of the N. and S., was subdued and laid waste by his grandson Khublai, with all the unrelenting cruelty of a Tartar conqueror; and he extended his influence and the terror of his arms over the circumjacent kingdoms of Corea, Tonquin, Cochin-China, Pegu, Bengal, and Tibet. A new dynasty of Mogul princes was established in China, under whose sway the country gradually settled; and in the succeeding generation the habits of the invaders were mollified by the influence of civilized life. Letters, commerce, and the arts of peace were revived, and the ancient system and machine of Chinese manners and policy resumed its accustomed action. One hundred and forty years after the death of Zinghis, his degenerate race were expelled by a revolt of the Chinese, and the native dynasty of princes, namely, that of Ming, was elevated to the vacant throne.

Persia was overwhelmed by the invasion of the Tartar armies under Holagou Khan, the grandson of Zinghis. The princes who ruled in the different districts of the country, under the titles of sultans, emirs, and attabeks, were successively crushed under this great conqueror, who, advancing to the Euphrates, stormed and destroyed the city of Baghdad, put the khalif to death, and thus for ever extinguished the line of the Abassides. Syria was overflowed by the torrent of invasion; Damascus and Aleppo were given up to pillage;[5] the kingdoms of Armenia and Anatolia were overthrown; and the sultans of Iconium, the last remnant of the Seljookian dynasty, were extirpated by the armies of Holagou. A. D. 1243.

The descendants of Zinghis had no sooner subverted the empire of China, than they resolved on the conquest of the Western World; and collecting a mighty host, they advanced from China to Europe, inundating the intervening space with their innumerable hordes, and extirpating the reigning powers in Turkistan, Tartary, and the northern plains of Asia. They penetrated into Europe with their victorious armies, of which detachments were sent northward to contend with the Russian princes for the frozen regions of Tartary. The unity

[1] De Guignes, in his learned and laborious work *Histoire des Huns*, gives a very clear narrative of the situation and boundaries of this kingdom, and of its final ruin by the invasion of Zinghis Khan. The fate of the sultan, formerly a conqueror, who, flying from the Tartar horse, took refuge in an isle in the Caspian Sea, where he requested a horse might be allowed to feed near his tent, as the companion of his solitude, and his solace in adversity, is particularly touching. See tome iii. livre 14.

Asia.

of the Mogul Empire, so firmly maintained by Zinghis Khan, was weakened by the extent of its conquests. According to its original constitution, all the other khans were the dependents or vassals of the great khan, under whose investiture they held their authority. But by distance, and the various mutations of time, those ties of allegiance were gradually loosened. The different branches of the Mogul family conformed, from policy or conviction, to the religion of the conquered countries, those who ruled in China to the idolatry of the Chinese, and the invaders of the Moslem territories to the Mahometan faith; and from this diversity of religion and manners divisions arose, which terminated in a lasting disunion. From A.D. 1240 till the rise of Timour or Tamerlane, about the year 1360, the Mogul power in Western Asia was shaken by intestine strife; and a crowd of emirs, sultans, and petty rulers contended, in incessant wars, for the fragments of the broken empire; while such of the Moslem potentates as survived the invasion of Zinghis, still maintained, by their valour, the balance of power in Syria against their Tartar enemies. The Ottoman line of princes, the permanent rulers of the country, were in the meantime slowly emerging into view. Amid the anarchy which reigned in Western Asia from the downfall of independent powers, and the rise of usurpers in their place, the country swarmed with a warlike population, with loose disbanded soldiers, and adventurers of every description. Among these were many of the Turkish hordes who had formerly pitched their tents on the southern banks of the Oxus, and the khan of one of those obscure tribes was the father of the Ottoman dynasty. Othman was the first of this line who, about the year 1326, by his conquests, laid the foundation of the Turkish Empire, which has ever since continued to rule in Syria and Asia Minor. About the year 1400 the Turks, under Bajazet, had acquired an extensive empire, the glory of which was for a time obscured by the conquests of Timour the Tartar, or Tamerlane, who began to acquire renown by his early conquests in Eastern Turkistan, or Transoxiana, about the year 1360, when he subdued the kingdom of Cashgar, and carried his conquests 480 leagues to the N.E. of Samarcand.[1] He finally extended his dominion to the Irtisch and the Volga; and in 1398, having previously reduced the Punjaub and the province of Moultan, he advanced across the intervening desert to Delhi, which submitted to his arms, and was abandoned to pillage. He proceeded northward towards the sources of the Ganges in a crusade against the idolatry of the Hindus, who were massacred without pity; and, after an expedition of five months, he finally retraced his steps to Samarcand, without effecting any permanent conquest. In the western countries of Asia he encamped and overthrew the rising power of the Turks under Bajazet, and extended his conquests over Syria and Asia Minor, giving over its flourishing cities, such as Aleppo, Damascus, Smyrna, &c., to the sword and the flame. The rise and progress of this great Tartar chief, and his rapid successes, rivalled those of Zinghis himself; but they were not on the same vast scale, nor had they such lasting effects. The kingdoms which were conquered by Zinghis were colonized by his soldiers and inherited by his children; but Tamerlane's conquests were more like predatory inroads; and though for the time he subverted the existing order of things, and trampled in the dust the princedoms and powers of the country, yet, as the flood of his invasion receded, those powers quickly resumed their sway. In Asia Minor the Ottomans speedily regained their ascendancy on the ruins of the Greek power. They reared up, in the middle of the fifteenth century, the permanent fabric of their empire. Towards the end of the same century Persia was, by a singular revolution, transferred from the Tartar chiefs to the dynasty of Seffavean kings, or saints as they were considered before their elevation to the throne. Under their rule the country continued without any material change, until it was invaded in 1722, and conquered by Mahmoud, the first of the Afghan rulers of Persia. The independence of Persia was vindicated by the rise of the celebrated usurper Nadir Shah, who, ascending the throne about the year 1730, quelled all internal dissensions, and re-established the Persian empire in its ancient greatness and glory. He restrained the Turks within the western boundary of the Euphrates; on the N. he extended his dominions to the Oxus, and awed by the terror of his arms the Usbecs and other wandering tribes of the desert; and on the E. he conquered Hindustan, which he plundered of its wealth, and fixed the Indus as the boundary of his empire. Under his successors Persia has decreased in extent of territory and in power, but has not been subjected to any violent revolution, and still continues one of the independent though declining empires of the E. In 1747 the Afghans, under the new dynasty of the Doorannee kings, resumed their independence, which they still retain. But the Doorannee Empire, which at one time extended over a vast region between the Oxus and the Indus, touching Persia and Hindustan, has melted away into several minor states.

Hindustan.

In Hindustan the influence of the Mahometan conquerors, which was firmly established in 1210, was gradually extended over the southern provinces, amid rebellion and massacre. The uncertain dominion of the country appears to have been shared among a crowd of tributary princes, who, from their intestine quarrels, became an easy prey to the invader. Delhi was the capital of the Mahometans; and their conquests were extended over Malwah, the Deccan (by which we mean the country between the Nerbuddah and the Krisna Rivers) and the Carnatic, which was ravaged from sea to sea. The invasion, or rather the predatory inroad, of Timour in 1398, did not subvert the Mahometan dynasty, which terminated in 1413 by the death of the monarch. The throne was then filled by a Seid, *i. e.* one of the race of Mahomet, whose posterity enjoyed it till the year 1450, when an Afghan took possession of it, and all Hindustan was divided into separate governments. After an interval of reviving prosperity, the empire, about the year 1516, fell again into utter confusion, which paved the way for the conquest of the country by Sultan Baber, a descendant of Tamerlane and of Zinghis Khan, who being driven from the provinces situated between the Indus and Samarcand, over which he reigned, determined to try his fortune in India. He crossed the Indus in 1518, and having defeated the emperor of Delhi, he established the dynasty of Timur, or the Mogul line as it has been termed, which was illustrated by two of the greatest princes that ever reigned in India, namely, 1*st*, Akbar, who, from 1555, reigned 51 years, and subjected to his sway all the provinces that had revolted, from Ajmere to Bengal; and, 2*dly*, by Aurungzebe, who, after deposing and imprisoning his father, the feeble Jehem Shah, the grandson of Akbar, ascended the throne in 1660, and died in 1707, in the 90th year of his age. In this reign the dominion of the Moguls was extended over the Deccan, the whole of which, excepting only the mountainous and inaccessible parts, was either entirely subjected, or rendered tributary to the court of Delhi.[2] His authority reached from the 10th to the 35th degree of latitude, and to nearly the same extent in longitude; and his revenue amounted to 32 millions sterling. The Mogul empire gradually fell to pieces under a succession of feeble princes; and about the year 1750 it was reduced to the city

[1] Gibbon, vol. xii. chap. 65.
[2] Dow's *History of Hindostan*, vol. ii.; Major Rennel, *Memoir of a Map of Hindostan*, Introduction, lxl.

of Delhi and a small tract of adjacent territory. The last imperial army that ever appeared in the field was defeated by the Rohillas in 1749; and during this period the whole country was one scene of commotion, all the viceroys and petty feudatories of the Delhi sovereigns,—the various mountain tribes, such as the Rajpoots, who ruled in Ajmere,—the Sikhs, who had become formidable, and had established themselves in Lahore,—and the Jats, a tribe also in the north of India,—contending in arms for independence. Nothing remains of Mogul greatness but the name, which was, and still is, used as the symbol of sovereignty, and the sanction of all political and civil rights.

The decline of the Mogul empire paved the way for the rise of the Mahratta power, which had already become formidable in India under its founder Sevajee. At his death in 1680 he had acquired considerable dominion on the western coast of India. The confusion and anarchy that followed the death of Aurungzebe greatly facilitated the Mahratta conquests; and in 1740 this growing empire, which was divided between two chiefs, the one residing at Poonah in the west, and the other at Nagpoor in the east, occupied the whole tract from the western sea to Orissa, and from Agra to the Carnatic.[1] The Mahrattas, thus daily gathering strength, and the Mahometans, were now the two great rival powers in Hindustan. The contest between them was brought to an issue in the memorable battle of Paniput in 1761, when the Mahratta host of 200,000 men was entirely overthrown, with the loss of the greater part of their army, and their best generals; and from that fatal day their power began to decline.

Rise of the British power.

The rise of the British power forms an important era in the history of India. The unwarlike inhabitants of Hindustan, successively subdued by the Greek, the Mahometan, and the Tartar armies, were now destined even more surely to fall under the science and discipline of Europe. The French maintained their ground in India only for the short period of 12 years, from 1749 to 1761. The British, who engaged about the same time in the wars and politics of India, were more successful. The battle of Plassy, in 1757, fought with Surajah Dowlah, nabob of Bengal, gave them a firm footing in the country. The war which followed terminated in their favour; and in 1765 they acquired the right of collecting the revenues of Bengal, which was in fact equivalent to the sovereignty of the country. The jealousies of the native powers, excited by the encroachments of the Europeans, gave rise to new contests. But victory was still the result of each new struggle; and all the wars undertaken against the British only tended to consolidate and enlarge their empire. The British dominions in India may now be said to extend, with little interruption, from the banks of the Indus to the frontiers of Burmah, and from Cape Comorin to the Himalaya. Our actual possessions in that country may be roughly estimated to comprise an area of 750,000 square miles, with a population of 100 millions. See HINDUSTAN.

Different Asiatic races.

Amid those revolutions, of which we have attempted to give a brief sketch, it is not surprising that some of the most ancient empires of Asia should have entirely disappeared; that populous cities should have fallen into decay and ruin; and that extensive countries, once the seats of wealth, commerce, and science, should now lie desolate. The Babylonians and Assyrians have been long blotted out of the page of history; and no traces of them remain in the population of the world. The kingdom of the Jews has also been overthrown; but this ancient race are still wanderers on the face of the earth, and are found in most parts of Asia. There are other five principal races, who, it is remarked by Sir W. Jones, have in different ages divided among themselves as a kind of inheritance, and who still occupy, the vast continent of Asia, with the many islands depending on it. These are the Hindus, the Chinese, the Tartars, the Arabs, and the Persians. The origin of those different races is a curious subject of inquiry, and must be sought for in the remotest antiquity, and from the doubtful analogies supplied by religion, manners, and language. Sir W. Jones, who has so well illustrated many obscure points of ancient history, is of opinion that Persia was the original seat of mankind, from which, as from a common centre, they have gradually spread over the earth. According to his learned hypothesis, deduced from ancient works and an examination of the primitive languages, a flourishing empire was established in Persia or Iran, in the earliest dawn of history; and the population consisted of the three distinct races of Hindus, Arabs, and Tartars. About the era of Mahomet, it appears that, besides the language in common use, the learned had a language of their own, which had the name of the Pahlavi; and there was the still more ancient and abstruse language of the Zend, in which some sacred books were written, only known to a sect of priests and philosophers. The Pahlavi he clearly proves to be of Chaldaic origin, and the Zend, from an imperfect vocabulary which he procured, to be a dialect of the Sanscrit, the ancient and learned tongue of the Brahmins in India. Having thus ascertained the analogy between the language of the ancient Persians and that of the Arabs and the Hindus, he concludes that they must have originally been the same nation; and that, as Persia could not be peopled from the east by the Hindus, whose religion forbids them to emigrate, nor by the Arabs from the west, as we have not the slightest tradition of any such emigration, both Arabs and Hindus must have come from Persia, since we may still trace in this country the remains of their respective tongues, all of which appear to have been derived from one common and more ancient root.

The people of Tibet are descended from the Hindus, and, according to the hypothesis of Sir W. Jones, who, on all those subjects unites solid reasoning with the most profound learning, have engrafted the doctrines of Buddha on their ancient religion. Their language, though it has been corrupted by an intercourse with the Chinese, still bears the traces of a Sanscrit origin. The Afghans or Patans, who occupy Afghanistan between Persia and Hindustan, are said to have sprung originally from the Jews; but their language, which is evidently of the Indo-European root, does not warrant this tradition. The Japanese and the Chinese are evidently derived from a common stock, their literature, religion, and manners being the same. The Burmese are considered by some ethnologists to belong to the Hindu race, though others give them a Tartar origin.

The Tartars or Tatars, under which appellation we include the hordes of shepherds who range over the vast plains of Asia, under the names of Scythians, Huns, Mongols, and Kalmucs, differ entirely from the Hindus and Arabs in features, complexion, and form, as well as in manners and language, and appear evidently to be a distinct race. Their language, which is the Turci or the Turki, of which the modern Turkish is a dialect, might, according to Sir W Jones, be easily traced to a different root from the others. This ancient Tartarian language he mentions, on grounds which it would not be easy to disprove, was current in Persia at a very early age; and hence he concludes that the Tartars formed part of the ancient population of Persia, and, along with the other two races, issued from that country to occupy the deserts of Asia. The Chinese, according to the same learned author, whose opinion is founded on the Sanscrit institutes of Menu, were originally a military tribe of the Hindus, who, abandoning the ordinances of the Brahmin

[1] Major Rennel, Introduction, lxxxv.

religion, and living in a state of degradation, emigrated eastward, and occupying the countries bordering on Hindustan, laid the foundation of the Chinese empire. But the whole country has been since overrun and conquered by hordes of Tartars; and from the intermixture of those two races have sprung the modern Chinese, whose coarse, broad, and Tartar-like physiognomy bears no longer the traces of their Hindu ancestry.

The tribes who inhabit the great Asiatic archipelago, which extends from Madagascar to the Philippines and the neighbouring peninsula of Malacca, bear in their features, language, and customs, the undoubted marks of the same origin; and as the Sanscrit may be traced as the root of most of the dialects spoken in these islands, they appear to be descended from the Hindus. But in the lapse of ages and in the various chances of war or migration, different nations may be intermingled; the original traits by which each was distinguished will then gradually disappear, so that it may not be possible to discern the traces of a common origin in the varieties of the same race. It is possible that the inhabitants of the great Indian archipelago may have come originally from Hindustan, bringing with them the Sanscrit tongue; although it is probable that they are sprung from the same stock as the people of the adjacent regions. Sir Stamford Raffles, not less distinguished by his eminence in eastern literature and antiquities than as a legislator and a statesman, is of opinion that the Asiatic islands were peopled from that portion of the continent which lies between Siam and China. "The less civilized of the tribes," he observes, "inhabiting the islands, approach so nearly in physical appearance to that portion of the inhabitants of the peninsula which has felt least of the Chinese influence on the one side, and of the Burman and Siamese on the other, and exhibit so striking an affinity in their usages and customs, as to warrant the hypothesis, that the tide of population originally flowed toward the islands from that quarter of the continent lying between Siam and China. But at what era this migration commenced—whether, in the first instance, it was purely accidental, and subsequently gradual, or whether originally it was undertaken from design, and accelerated at any particular periods by political convulsions on the continent, we cannot at present determine, as we have no data on which to rely with confidence. It is probable, however, that these islands were peopled at a very remote period, and long before the Burman and Siamese nations rose into notice."[1] Mr J. Crauford, who resided for nine years in the Asiatic islands, and whose history of those countries displays extensive research, and a profound knowledge of Eastern literature and antiquities, adopts a different hypothesis respecting the original population of the Indian archipelago. He describes the original inhabitants as consisting of two races, one a brown-complexioned people, with lank hair, and in their persons short, squat, and robust, supposed by other writers to be Tartars; and the other, a negro race, of a puny stature and feeble frame, in complexion black, or rather sooty-coloured, with woolly or frizzled hair. The brown-coloured race compose the civilized portion of the people; and they have supplanted the negroes, who are constantly found in a savage state in Sumatra, Java, and Celebes, where civilization has made the greatest progress; while in New Guinea and other islands the negroes are almost the sole inhabitants. The origin of these two races, and the period when they settled in the Asiatic islands, is, according to Mr Crauford, buried in the remotest antiquity. The Tartar origin of the one race, though supported by many writers of learning, and the African origin of the negroes, is treated by him as absurd and unfounded. "Either hypothesis," he observes, "is too absurd to bear the slightest touch of examination. Not to say that each race is radically distinct from the stock from which it is imagined to have proceeded; the physical state of the globe, the nature of man, and all that we know of his history, must be overturned to render these violent suppositions possible." Dr F. Buchanan, Sir Stamford Raffles, and others, deduced the Tartar origin of those insular tribes from their form and features, which is the best evidence we can have where history is silent. The prevalence of the Sanscrit language in these islands has also, and with apparently some reason, been supposed to indicate the quarter from which the tide of population flowed; nor is it easy to see how the migration of a people from the continent of Asia into this archipelago is at variance with the "physical state of the globe, the nature of man, and all that we know of his history." Mr Crauford traces the various languages of the Asiatic islands to one common root. From this fact he concludes those islanders to have all sprung from one source, and he fixes on Java as their original place of settlement. Here he supposes they took up their abode when they were little better than wandering savages; whence they gradually spread over the other islands. Now it is on the same ground that others trace their origin to some continental nation of great antiquity. The language of a nation may throw light on its origin and its subsequent migrations; and in the present case it is admitted by Mr Craufurd that there is a large infusion of Sanscrit in all the Polynesian tongues; that it is "a more essential, necessary, and copious portion of the insular languages than Arabic;" that it exists in "a state of as great purity as the articulation and alphabets of the archipelago would admit, nearly unmixed with any modern dialect of which it is a part, and apparently in a state of original purity;" and that it is "pure and abundant as each dialect of the same tongue is improved, and rare and corrupt as the language is common and popular."[2] Sanscrit words, according to those who are versed in both languages, abound in the court dialect of Java in the proportion of three to four, and seem to constitute its basis; in the Kaw, or learned language of the priests, they occur still more frequently, and in their original purity; they are also common in the written language, and are found, though not so generally, in the ordinary dialect of the people. The existence of Sanscrit to such an extent in the languages of Java and the other islands, does not, according to Mr Crauford, prove that these islands were peopled by emigrants from Hindustan. He acknowledges that the fact of the Sanscrit not being mixed in their languages with any living dialect of India, is somewhat puzzling, and not easily reconciled to his theory; but on farther consideration, he thinks this fact tends rather to explain the manner in which it was introduced, which he ascribes to a few Hindu missionaries or priests brought to those islands from a desire to propagate their religion. They would naturally, he supposes, use the Sanscrit in teaching the mysteries of their faith, which, being mixed with the common language of the country, would form the Kaw or learned language of the priests, and would thence be diffused in a corrupted state over the common dialect of the people. From the prevalence of Sanscrit to such an extent in the Polynesian dialects, as well as from the ancient monuments of Hindu idolatry which are foun everywhere in those islands, it seems highly probable that they must, at a very early period, have been the seat of a Hindu empire, which has disappeared in the lapse of ages, while the Hindu superstition has been supplanted by the Mahometan creed. Whether this empire was established by conquest in that early period, while the Sanscrit was yet

[1] Sir S. Raffles' *History of Java*, chap. ii.

[2] *History of the Indian Archipelago*, by John Crauford, F.R.S., vol. ii. chap. v.

Asia.

a living language, or whether the Hindus were the original settlers in these islands, and afterwards, from the intermixture of other races, lost the traces of their ancient lineage, are points which lie hid in the darkness of antiquity. It does not seem very credible, however, that a small number of Hindu missionaries should have had influence, as Mr Crauford supposes, to change the language of the people, and to substitute for the ancient religion of the country their own foreign superstitions. So great a change seems more probably to have been produced by foreign conquest, or by a large immigration of the Hindu people.

The Malays.

Of the various races which people the islands of Asia, the Malays appear to deserve particular notice. Sir W. Jones supposes them to be descended, since the time of Mahomet, from the Arabian traders and mariners who frequented the Asiatic archipelago. But by later and more accurate inquiries they are now ascertained to have been originally settled in Menangkabau, in the centre of the island of Sumatra, and to have ruled over the whole country, from which they sent out colonies to the other islands. The Malayan annals examined by Mr Marsden,[1] and other documents, satisfactorily prove that, so far from emigrating, as was generally supposed, from the peninsula of Malacca to the Asiatic islands, they were original settlers in Sumatra, from which they issued to invade and conquer the Malacca peninsula; and they had established a powerful empire prior to the Mahometan conquests. The Malays profess the Moslem creed, which was introduced about the end of the thirteenth century, and has made rapid progress among all those islanders. But their original religion was that of Brahma, blended with the antecedent rude idolatry of the country, such as is still seen among the Battas. The Malay adventurers who invaded the Malacca peninsula in the 12th century conquered the country; and the indigenous inhabitants, so far from being the stock from which the Malays have sprung, are an entirely different race, resembling more nearly the negroes of Africa. The Malayan empire, which extended all over Sumatra, is now dismembered, though its colonies have been found on the coasts of the Malacca peninsula, and throughout the islands as far east as the Moluccas.[2] The Malayan language is spoken without any mixture in the inland country of Sumatra; it is understood everywhere, and has extended over all the eastern islands. The Bugis in the island of Celebes are a well-known race in the eastern archipelago. During the flourishing era of the Malayan empire in Sumatra they had established that of Guah or Mengkasar in Celebes on the east: like the Malays, they sent forth numerous colonies; and at one period extended their conquests as far west as Acheen in Sumatra and Keddah in the Malayan peninsula; and in almost every part of the archipelago Malayan and Bugis settlers are to be found. In all those Asiatic islands there is, however, an indigenous race, who were settled there prior to the Malays or the Bugis; and these last appear to have been intruders, but at what period of the world cannot now be known. The native inhabitants of Sumatra, Java, and the other islands, differ from them in character, habits, and features. The Battas, in the interior of Sumatra, are a distinct people, with their own peculiar habits and language: they have been reproached by travellers for eating human flesh, of which Sir Stamford Raffles produces undeniable evidence. The natives of Java are a quiet, contented race, attached to the soil, and have not the roving, maritime, and piratical habits of the Malays.

Number of inhabitants.

With regard to the number of inhabitants in Asia, we have no data for any accurate estimate. The Asiatics possess no statistical knowledge; and, excepting surveys instituted by government for the purposes of taxation, no other political inquiries are ever set on foot by authority. The various accounts of the Chinese population differ to the extent of 100,000,000. Those regarding Persia, Hindustan, the Asiatic islands, &c. are little more to be depended on; and still less can we expect any accurate census of the roving population of Arabia or Tartary.

Character and manners of the Asiatic nations.

The character of the Asiatics is represented in a very unfavourable light by all travellers. Lieutenant Pottinger, who travelled in Hindustan, Persia, and other countries, asserts that moral turpitude may be said to pervade the population and society of every nation in Asia of which we have the slightest knowledge:[3] and this description is confirmed by other travellers, who describe the people to be dissolute in their morals, of cold and selfish dispositions, and withal cruel and treacherous; without any regard to truth, and indulging, without either restraint or shame, in the most scandalous crimes. Of all the nations in Asia the Persians are reckoned to be the most refined; and yet, according to Herbert, Chardin, and others, and more recently Fraser, Pottinger, and Sir J. Malcolm, they are stained with all the Asiatic vices of cruelty, meanness, lying, and the grossest licentiousness.[4] The Hindus do not rank higher than the Persians in the scale of morality; and among the Burmese and other eastern states the treatment of women, who are held to be an inferior class, and are sold into slavery by their husbands and parents, and the cruelties which they commit in war, besides other revolting customs, indicate a state of manners which, contrasted with those of Europe, may be justly considered barbarous.[5] Of the low state of morals among the Chinese we need seek no other evidence than the inhuman practice, which is known to prevail in all the populous cities, of exposing new-born children to perish on the streets. There is no truer mark of barbarism than an indifference to the sufferings of our fellow-creatures; as on the other hand it is only in a highly civilized community that man is trained to the exercise of social benevolence. The savage is always found to be cold, unsocial, and selfish: in the progress of society this selfish principle is corrected; man is impressed with the duties which he owes to his fellow-men, and is taught to know experimentally, that it is not in the selfish pursuit of his own good, but in the mutual interchange of benefits, that the greatest sum of individual happiness is to be found. If we examine the manners, institutions, and policy of different nations, it will be seen that mankind are humane and moral exactly as they are instructed; and that as the diffusion of knowledge leads to the practice of all the social virtues, ignorance as surely produces cruelty, selfishness, and vice. Thus, among the Persians and Turks cruelties are committed which would be repudiated by the more advanced civilization of Russia; and in illustration of the same principle we may here mention a circumstance which serves to place in an equally striking contrast the manners of the English and the Chinese. An

Asia.

English vessel happened to be at anchor in the roads of Canton, when a Chinese boat was overset, and the crew precipitated into the water. The accident was observed by numbers of the Chinese, who beheld with the utmost indifference their countrymen struggling for their lives. But the officers and seamen of the English vessel instantly lowered their boats, and were seen, with all their usual zeal in the cause of humanity, striving to save the lives of those who were entire strangers to them. Now we cannot have a surer index to the station which each nation holds respectively in the scale of civilization, than the opposite conduct which they severally pursued in this case; and this insensibility to human distress is not peculiar to the Chinese; it seems to pervade the whole population of Asia; while in Europe we see everywhere proofs of active benevolence,—the most munificent establishments for the relief of misery; hospitals for the sick and infirm; houses of refuge for the aged, the blind, the destitute, and the insane; besides charitable associations of every description. For all the afflictions to which frail humanity is subject, the active sympathy of Europe supplies a remedy; and the spacious structures which, under the influence of this feeling, have been reared up in all the European towns, are at once the splendid monuments of humanity and of high civilization. In Asia the rich and the powerful associate, not to relieve, but to oppress the poor; and throughout its wide extent no asylum for distress, nor any charitable institutions, are to be seen. The miserable are left to their fate, which is generally to die unpitied, either of famine or disease. There is no part of Asia in which intelligence is widely diffused among the people; and hence, while they are to "vice industrious," they are to "nobler ends timorous and slothful." Yet in the exterior pomp and show of the Asiatics there is something specious and imposing; and the rich magnificence of their flowing robes, their gorgeous palaces, their splendid mosques and gilded temples, are calculated to raise ideas of high improvement, which a nearer inspection fails to realise; and, after all, what is there in this tinsel glare of oriental luxury that can be compared to the severe simplicity and solid refinements of Europe.

This degraded state of society seems to be the joint effect of tyranny and superstition. In Asia there is no government which wears even the semblance of freedom. In form, as well as in practice, they are purely despotic, the princes being tyrants, and the people slaves. Nor is the power of the prince controlled by the influence of manners, as in Europe, where the monarch, however absolute, seldom indulges in the licence of despotic sway, and where life and property are fully protected. The manners of Asia favour the exercise of unlimited power; and this vast continent is accordingly one scene of excess and misrule, where the mere will of the monarch is a warrant for the proscription and death of any individual, however powerful, and for the ruin of his family. The people, ruled according to those severe maxims of despotism, live in continual dread of violence and wrong; and they naturally resort, in self-defence, to fraud, falsehood, and treachery, which are the resources of weakness. Thus all sense of independence is at last extinguished; and under the iron rod of their political masters they degenerate into abject slaves, without honour, intelligence, or morality. Despotism in Asia assumes so severe a character, that it invades the security of private life, relaxes all social ties, and re-acting on the people with its pernicious influence, tends still farther to debase them, and to fit them for the endurance of its degrading yoke.

The prevailing superstitions of Asia have had their due share in corrupting the manners of the people. In Asiatic Turkey, in Arabia, Persia, and partly also in Hindustan and the Asiatic isles, the people have adopted the Mahometan faith; in Hindustan they have followed the religion of Brahma; and in Thibet, and farther eastward among the Burmese, in China, and the isles of Japan, the religion of Buddha or Foe is universally established, which, however corrupted in its various forms and idolatries, is still known to be derived from the Brahminical faith. Now all those different systems enjoin a variety of minute observances, and tedious pilgrimages and penances, a strict compliance with which constitutes the essence of religion. A pilgrimage to Mecca, for example, atones for all the iniquities of a Mahometan life; and the Hindus and others have their pilgrimages and penances for the expiation of guilt. A relaxation of morals is the consequence; and hence in those eastern countries a strict profession of religion is not inconsistent with the most scandalous crimes.

The sanction given to polygamy by all the systems of religion in the East has also tended to encourage licentiousness. Mahomet found it convenient to allow this indulgence to his followers; and the Hindus, the Burmese, the Chinese, and most of the other Asiatic nations, follow the same rule. In all Christian countries marriage is respected as a sacred and an honourable tie, equally binding on both parties; and experience proves, that where its obligations are duly fulfilled, it is calculated to produce all the happiness and virtue which can be attained by man in this sublunary state. In the intercourse of a European family the best affections of our nature are called forth. Here, as the poet expresses it,

Flows the smooth current of domestic joy;

and in those scenes the rising generation receive, from the example and tuition of parents, those just and early impressions, which are never erased. How different are the baneful consequences of polygamy, which, being contrary to the order of nature, must be upheld by tyranny, and which degrades the weaker sex, from being the free and equal companions of man, into the slaves of his pleasures. The domestic tyrants of the East rule with absolute power over all the inmates of the harem; any of whom, in a fit of rage or jealousy, they may consign to a cruel death, no eye witnessing the deed. The effect of polygamy in this manner is not merely to taint the morals of society, but the laws and policy of the state. It establishes a tyrant, not on the throne, which would be the lesser evil, but at the head of every family; and on his unruly passions the law imposes no restraint. Hence in Asia domestic comfort, so much prized in Europe, cannot be known. An Asiatic family is not the abode of purity and of domestic peace, but of licentiousness and strife; the husband and father the object of terror rather than affection; the women his abject slaves, leading a life of jealousy and malice, and often conspiring against each other by the most diabolical arts. The institution of polygamy, which in this manner converts one half of the community into tyrants and the other half into slaves, has proved, in every country in which it has been introduced, the bane of morality as well as of social peace. In Europe the purer influence of Christianity, consecrating the marriage union, and impressing on man a just consideration for the other sex, has raised them to the rank in society which properly belongs to them. It has released them for ever from the bondage of tyranny and vice; and under its mild and beneficent maxims the nations of Europe have attained to a degree of morality, refinement, and intelligence, which distinguishes them to their advantage above the most polished nations of antiquity, and presents a decided contrast to the licentiousness and misery of the East.

Manners of the pastoral tribes.

But if such be the state of society among the civilized inhabitants of Asia, what, it may be asked, is the condition

of its rude tribes? Among those semi-barbarians who have no fixed habitations, but who dwell in tents, migrating periodically with their flocks in quest of pasture, all crimes of violence, such as rapine, revenge, and murder, prevail without any restraint. The pastoral tribes of Asia retain all their Tartar habits of ferocity; robbery is their daily occupation, handed down from father to son; and they are perpetually engaged in predatory inroads, in which they carry off as their lawful prey all that they can seize—corn, cattle, goods, and men and women, who are sold for slaves. If any traveller were to venture within this region of violence, he would be robbed and murdered without mercy; and no merchandise can be transported from one place to another without a sufficient escort. The regular commerce of Asia is in consequence carried on in caravans, or large companies of merchants, who travel together for safety; and even these are not secure from the savage tribes, the remnants of the Tartar population, who inhabit the mountains and central plains, and who frequently emerge from their fastnesses in great force for the purposes of plunder. Such were the shepherds who, under Zinghis Khan and Tamerlane, issued forth in innumerable bands, subverting the great empires of the world, and extending their dominion from sea to sea. But various causes have concurred to circumscribe their power. Among these we may reckon the invention of fire-arms, which in war gives the entire ascendancy to civilized nations. Prior to this invention the weapons used were extremely simple, and could be easily fashioned by the rudest tribes. In archery, or in the use of the sling, the merest savages may excel; and for a close encounter the spear or the sword could be easily procured, and as effectually wielded by a barbarian as by any other arm. But the *matériel* of modern war is far more complicated and expensive, and cannot be procured without the aid of wealth, and the nicest mechanical art as well as science; so that it is justly observed by the historian of Rome, that in the present state of the military art, a nation must be civilized before it can conquer other nations. Since the invention of fire-arms the superiority of civilized over barbarous nations has been seen in every encounter which has taken place, and "the reign of independent barbarism has been contracted within a narrow span."

The extensive region of Tartary, which occupies the centre of Asia, has never been very distinctly defined; but it is surrounded on all sides by the civilized empires of Asia,—on the north by Asiatic Russia, and on the south by Persia, Hindustan, and China; and as the use of fire-arms has augmented the military strength of these different states, they have gradually extended their sway over the savage tribes on their frontiers. Russia, which was overrun by Tamerlane and other conquerors about the end of the 14th century, was, after about 200 years of obstinate and bloody wars, emancipated from the Tartar yoke; and it has ever since been making reprisals on its barbarous enemies, having reduced the tribes on its frontiers—the Kalmucs, the Bashkirs, the Kirghises, who inhabit the banks of the Volga and the country on the shores of the Caspian Sea, besides numerous other Tartar tribes on the Chinese frontier, near the sources of the Irtisch, the Obi, the Yenesei, and the Lena. Her wars with the Turks also, an Asiatic tribe, though of a different origin from the broad-featured race of Tartars, exemplify in a striking manner the warlike superiority of civilized nations. The contests of China with the barbarous hordes of Mongols, Kalkas, and Eluths, to the west and north-west of her territory, and with the Mantchoo Tartars, who inhabit the country to the north, bordering on the Pacific Ocean, have also terminated in their entire subjection. They have been successively subdued by the Chinese armies; and the missionary Gerbillon, giving an account of a great victory gained by the Chinese, ascribes it to the superiority of their artillery, which the barbarians had no means of opposing. Persia has been long a feeble power; and the Tartar tribes who range along her northern and eastern frontiers are still extremely powerful, and frequently molest the adjoining countries by their incursions. Independent Tartary may now therefore be comprised within the following boundaries, namely, the Altai Mountains on the north, which form the southern boundary of the Russian empire; the Caspian Sea on the west; Chinese Tartary on the east; and Persia and Hindustan on the south. These boundaries inclose a space of about 1200 miles in length, from the Altai Mountains to Persia; and 900 in breadth, from the Caspian Sea to Chinese Tartary. To this must be added the country between Hindustan and Persia, including Sinde at the mouth of the Indus; and westward the mountainous regions of Beluchistan, as well as Afghanistan. In the high district of Balk, which is within this space, and which is situated on the northern declivity of the Hindu Koh or Himalaya Mountains, and in Buckharia or Bokhara, on the fertile banks of the Oxus and the Jaxartes, where the towns of Bokhara, Samarcand, Khivah, Koukan, Khojund, and Murghelan, &c. some form of civil order is maintained by the independent princes of the country; but with these exceptions the Tartar manners still prevail throughout this extensive region. The towns are thinly scattered, and the pastoral hordes range over the face of the land in all the licence of savage freedom. These consist, not of the Tartars who possessed the country in the time of Tamerlane, but of the Usbecks, a Turkoman tribe, who appear to have descended, with the whole mass of their people, from the inhospitable countries in the north, to the fine plains of the Oxus and the Jaxartes, and to have expelled the Tartars, whose place they now occupy. The Turkoman tribes, who inhabit the Elburz Mountains to the south of the Caspian, and the deserts of Kharasm, which extend eastward from this interior sea about 600 miles, are described by Fraser, in his instructive work on Persia, as singularly fierce, cruel, and blood-thirsty in their habits. They pour down from their deserts in great force on the cultivated districts, plundering villages and caravans with every circumstance of atrocious outrage, murdering on the spot the old, the feeble, and the helpless, and carrying into slavery those who are fit for labour, and thus depopulating extensive tracts that were before fertile and well inhabited. On the east of Persia the same ravages are committed by other tribes, who dispose of their captives to slave merchants, by whom they are carried to the markets of Bokhara and Khivah. On the south the wild inhabitants of Beluchistan, so well described by Lieutenant Pottinger, one of the most judicious and enterprising travellers of modern times, plunder and murder their prisoners, or carry them for sale to some of the great slave-markets in the East. Numerous tribes of shepherds feed their flocks on the banks of the Oxus and the Jaxartes; and they are found scattered over all the northern and eastern countries of Central Asia, as far as the boundaries of Russia and China. But in the present improved state of the military art they are no longer formidable, and they waste their force in casual inroads, which are easily repelled.

Progress of discovery in Asia.

From the earliest ages the countries of Western Asia, namely, Asia Minor, the valley of the Euphrates and Tigris, and Persia, were familiarly known to Europeans; but of the northern plains inhabited by the Scythian tribes, and of the rich and improved countries of Hindustan and China in the east, they were only informed by vague and inaccurate reports, which were slowly corrected by the progress of commerce or of conquest. Of the ancient

expedition of Semiramis into India we know nothing more than that her armies were forced to retreat with loss. But the subsequent invasion and conquests of Darius extended the knowledge of the Europeans to the modern provinces of Lahore and Moultan, commonly called the Punjaub, or the country watered by the five head branches of the Indus. Herodotus describes the climate of the country as intensely hot; the inhabitants in some points as little better than barbarians; and with a small grain of truth he mixes the strangest and most absurd fables. He mentions the populousness and wealth of the country, and the staple produce of cotton or wool growing on trees; the story of the white ants turning up the earth and digging up gold, which has been copied by succeeding writers; and, finally, the region of the five rivers as bounded by a barren plain, which must no doubt be the sandy desert that lies between the valley of the Indus and the Ganges. The Scythians or Tartars who wandered over the northern and eastern plains of Asia were only known by their irruptions into Europe. The two tribes of the Massagetæ and the Sacæ, the former inhabiting the desert plains to the east of the Aral and north of the Jaxartes, and the latter the country to the north-west of India, are mentioned by Herodotus and other ancient writers; and their description is merely a detail of pastoral manners. The expedition of Alexander into India was a great step in the progress of Asiatic geography. This warlike prince was intent not merely on conquest, but on the diffusion of arts, commerce, and science; and, like some modern conquerors, his army was accompanied by a body of men of science, who were instructed to measure each day the distance traversed, to make an accurate table of the various routes, and to observe and describe the countries through which they passed. Science thus followed in the train of arms; and it was by a European army that the remote regions of the East were first explored. Alexander pursuing his victorious march through Asia Minor, passed the limits of European discovery, and entered the eastern country of Bactriana in pursuit of the Persian army. Having passed the Paropamisan range of the Himalaya Mountains, crossed the Oxus, and taken Maracanda, the modern Samarcand, he advanced northward to the Jaxartes, where he pursued the Scythian host into the northern deserts to the eastward of the Aral. Retracing his steps, he again crossed the Paropamisan Mountains, and advancing eastward among hostile tribes, through the modern country of Cabul or Afghanistan, to the south of the Hindu Koh range, he crossed the Indus near the mountains, and having defeated the Indian army of Porus, he obtained the command of the country watered by the five tributary streams of the Indus, where his course was arrested by the murmurs of his troops, who refused to follow him across the desert to the Ganges. Still intent on discovery as well as on conquest, he fitted out a large fleet, and sailing down the Indus to its mouth, in the Indian Ocean, he instructed his admiral, Nearchus, to return to Persia by sea, while he took his course through the modern country of Mekran, and was nearly lost with his whole army in its sandy deserts. Nearchus directed his course along the shores of Asia, and triumphing over the perils of unknown seas, arrived safely in the Persian Gulf, which he ascended to the mouth of the Tigris. This is the first great voyage of discovery of which we have any authentic account; and considering the age of the world in which it was accomplished, it must be viewed as a singular display of courage and of nautical skill. Alexander was not equally successful in tracing the connection of the Red Sea with the Indian Ocean, which remained unknown until the reign of the Ptolemies in Egypt.

Seleucus, the successor of Alexander, carried his arms into India for the purpose of completing its conquest; but he does not appear to have reached the valley of the Ganges. He sent, however, to the court of Sandracottus, an Indian prince who reigned over all the countries from Delhi to the mouth of the Ganges, his ambassador Megasthenes, who acquired the most important and clear information respecting those unknown regions. He visited the celebrated city of Palibothra, the site of which has so much perplexed modern geographers; and, with some admixture of fable, he accurately describes the countries on the Ganges, and their productions; the amazing size of the rivers; the most remarkable animals which he saw, among others the Bengal tiger; and the manners of the people, and their division into castes, with other singular customs.

During the reign of the Ptolemies in Egypt the geography of Asia was still farther illustrated, not by conquest, but by commerce. Alexandria was at that time the great emporium of the eastern trade; and India was explored in its most remote parts, for the precious commodities which it was supposed to produce. The Egyptian mariners entering the Indian Ocean from the Red Sea, and coasting along the Arabian shore, stretched across the Persian Gulf by the help of the south-west monsoon, to the mouth of the Indus, whence they sailed southward along the Malabar coast, and doubling Cape Comorin, extended their voyage on the coast of Coromandel as far as the modern city of Masulipatam.

In the age of Ptolemy the geographer, which was a century later, the knowledge of the Europeans had extended eastward beyond the Ganges to the Burman empire and the Gulf of Siam, though it does not appear that the navigators of antiquity ever reached the Chinese coast. The commerce of India was carried on by land as well as by sea; and regular caravans commenced their route from Byzantium eastward through Asia Minor and Persia, passing through the modern cities of Hamadan and Herat; and journeying northward, and crossing the Oxus and the modern country of Bokhara, they passed the great branch of the Himalaya Mountains which runs northward from the main range under the modern appellation of Bolor Dagh; and descending into the lower plains of Little Tibet, they assembled in great numbers, and, after halting for some time, took their journey to the capital of Serica or China, which occupied a period of seven months. The description given of the Seres as a frugal and mercantile people, averse to all intercourse with strangers, and carrying on their trade at a single station on the frontier, answers entirely to the modern character of the Chinese. The commerce, which during the flourishing era of Rome was carried on between Europe and the eastern parts of Asia, was interrupted by the inroads of the barbarous nations who assailed, and in the end overthrew, the Roman empire; and all knowledge of Asia was for a time lost. It was not till the 6th or 7th century, during the reign of the caliphs at Bagdad, that the Arabian geographers acquired a knowledge of those countries. During this period the country to the west of the Bolor Dagh Mountains, which stretch northward nearly to the frontier of Siberia, consisting of extensive plains, watered by the Oxus and the Jaxartes, was well known to them; and they were imperfectly acquainted with the southern plains of Asia inhabited by the Tartars, though they were as usual the subject of fables. The eastern countries of Hindustan, the beautiful region of Cashmere, the great Asiatic plains, and China, with the island of Sumatra and others, were known to the Arabian geographers, though they seem to have had no correct knowledge of the Asiatic shores. Their accurate description of Chinese manners leaves no doubt of their having reach-

ed that country. The invasion of the Holy Land by the crusaders tended, among its other consequences, to introduce into Europe a knowledge of those countries in Asia which were famed for wealth and the remains of ancient refinement; and from the camps of the crusading kings, as well as from the pope, some remarkable embassies were sent to the Tartar sovereigns, the descendants of the conqueror Zinghis, the site of whose capital of Karrakorum is now the subject of dispute, though it is generally agreed that it must have been situated far east, in the wilds of Tartary. The object of the embassies dispatched by the pope to the Tartar camp was to divert the storm of barbarian invasion from Europe. The ambassadors were friars, who were carried to the head-quarters of the Tartars, in the eastern wilds of Asia, through countries which had never been explored by any European. Rubruquis, a friar, who was sent ambassador by St Louis to the Tartars, has given a lively and circumstantial account of his adventures. He reached the Tartar capital of Karrakorum after a fatiguing and dangerous journey of more than two months, having traversed a vast tract of unknown country, and brought to the knowledge of the Europeans the immense plains and high lands of Central Asia, Eastern Tartary or the country of the Mongols, Thibet, and Cathay or China, and the eastern shores of the continent. All those countries were afterwards visited by the celebrated Venetian traveller Marco Polo, who, being dazzled by the splendid accounts diffused through Europe of the wealth and luxury of Asia, was inflamed with the desire of exploring those distant countries. He accordingly proceeded through Asia Minor, Persia, the high country of Balk, visited the cities of Cashgar and Yarkund, and skirting the great desert of Shamo or Cobi, he reached the Tartar capital of Karrakorum, and finally entered the Chinese empire, of which his account is circumstantial and correct, and of which some of the magnificent cities, though they have fallen from their ancient importance, are still recognised in his accurate description. He returned to Venice by sea after an absence of twenty-four years, having obtained accounts of the eastern islands of Java, Sumatra, Ceylon, and of Ormus in the Persian Gulf, at that time the great and splendid emporium of the Indian trade. The discovery, in 1498, of the passage to India by the Cape of Good Hope, opened the Indian seas to the European fleets; and shortly after this great event, the southern, and partly also the eastern shores of Asia, were completely explored, as well as that great archipelago which extends from the Malacca peninsula to New Holland. In the interior of the continent the progress of discovery was much slower, and only kept pace with the gradual extension of the Russian dominion over the barbarous tribes in Northern Asia. The Tartars under Tamerlane in 1382 had invaded the east of Europe, had taken Moscow, and overrun all the countries on the Volga and the Dnieper. The rise of the northern empire was for more than two centuries obstructed by the inroads of the barbarians; and it was only after long and obstinate struggles that they yielded to the superiority of the Russian arms. About the middle of the 16th century Russia had extended her conquests to the Obi, and her empire was enlarged northward and eastward, until it reached the frontiers of China and the Pacific Ocean. The general form of the continent, which was exhibited in the maps from mere conjecture, was in this manner laid open to Europeans; and in the course of the last century the eastern and northern shores were surveyed; also Kamtschatka, the Kurile Islands, and Jesso. The islands of Japan had been previously discovered by navigators. The relative limits of the Asiatic and American continents were traced by Behring, Tschirikoff, and other navigators, who also discovered the Aleutian or Fox Islands; and finally by Captain Cook, who advancing into Behring's Straits as far as the parallel of 70° 44′, ascertained the near approach and true bearing of the two continents.

The interior countries of Asia near the Caspian and Aral Seas have been visited by Russian travellers, who have corrected some errors of long standing in Asiatic geography. Lake Aral was either unknown to the ancients, or they confounded it with the Caspian Sea, of which they supposed it to form a part, and to be the receptacle of the great river Oxus. After the fact of two separate seas was fully known, the Oxus was still supposed to terminate in the Caspian; and its course was laid down accordingly in all the most approved charts. The Russians, having visited those countries, ascertained by actual observation that the Oxus, as well as the Jaxartes, terminates in the Sea of Aral. There seems, however, an ancient channel by which at least one portion of the waters of the Oxus at one time may have found their way into the Caspian, as mentioned by ancient authors.—Humboldt, *Asie Centrale*, ii. 296.

Eastern Asia, namely, the Chinese empire, with the source and termination of all its great rivers; the northern country of the Tartars; the course of the great river Amour; with the high lands of Central Asia, namely Mongolia, the original seat of the Mongols, were in the course of the sixteenth and seventeenth centuries explored by the Romish missionaries, as well as by mercantile travellers. In 1624 Antonio d'Andrada, a Jesuit, travelled from the coast of the Great Mogul to China. He passed through the country of Serinagur, and ascending the great Himalaya range, he and his companions endured such incredible hardships that he was forced to return. He afterwards crossed these mountains along with a caravan, and was among the earliest travellers who reached the country of Tibet, which he describes, and also the manners and religion of the people. In 1603 the missionary Goez set out from Lahore, where he resided at the Mogul court on his way to China. He travelled westward, and crossing the Indus, passed through the countries of Kabul or Afghanistan, Cashgar to the N., and the country on the banks of the Oxus; and crossing a ridge of the Himalaya Mountains, he arrived at Yarkund. From this place he journeyed with a caravan across the central country of Mongolia to China. These missionaries were received into high favour by the Chinese emperors, who valued them on account of their science, and gave them access to the public archives, which contained all the Chinese surveys of the empire and of the adjacent countries. By the help of these they exhibited with accuracy the interior geography of Tibet, and also of that extensive country beyond the Ganges which now forms the Burman empire, and which is watered by the great rivers that take their rise in the central mountains and run southward,—the Irawaddy into the Indian Ocean, the Setang into the Gulf of Martaban, of which it forms the estuary, the Saluen into the same gulf, the Menam into the Gulf of Siam, and the Menam Kong or the Mekong into the Chinese Sea.[1] These missionaries prosecuted with equal activity and zeal their inquiries into the interior geography of China;[2] they traced the great

[1] See Crauford's *Journal of an Embassy to the Courts of Siam and Cochin-China*. Geographers are not agreed on the respective appellations of these rivers: in this we have been guided by Mr Crauford.

[2] For a more detailed account of these missionary travels the reader is referred to Hakluyt's *Collection of Voyages*; Purchas' *Pilgrims*; *Histoire Générale des Voyages*, Paris, 1749; and to the *Historical Account of Discoveries and Travels in Asia*, by H. Murray, who has given an equally learned, judicious, and comprehensive abstract of all the existing information on the subject of Asiatic geography.

rivers the Hoangho or Yellow River, and the Yank-tse-Kiang or Blue River, to their termination as well as to their source, which they found to be in the depths of the central mountains, and not in the imaginary lake of Cayamay, as had been generally believed. Grueber, who set out on his travels to the East in 1656, traversed the whole country of China, partly by land and partly by water; and his route to Europe was through the Tartar deserts to Lassa, a town in Tibet, and thence through the mountainous country of Nepaul to Battana on the Ganges, Benares, and finally to Agra, which he reached after a journey of more than twelve months. Other journeys equally enterprising were also undertaken by the missionaries. Desideri set out in 1714 from Delhi, and travelled across the Himalaya Mountains through Cashmere into Tibet; and, at a later period, Horace de la Penna, with a body of twelve missionaries, resided in the same country for a number of years. The missionary Gerbillon, who was in great favour at the Chinese court, travelled in 1688 through the Tartar deserts, with a Chinese embassy, to the banks of the Selingha, there to settle with the Russians the respective limits of the two empires; and having been also in the practice of following the emperor in his hunting expeditions into Tartary, he contributed with other travellers to illustrate the geography of these countries and the manners of the people.

The great extension of the British conquests in Northern India has laid open to Europeans all that portion of Asia which lies on the southern declivity of the Himalaya Mountains, which is interesting not only from its natural grandeur, but also as it contains the sources of the Indus, the Ganges, and the Brahmapootra. The Europeans were indebted for all the knowledge which they possessed of those countries to the Chinese missionaries, who represented the Ganges to rise on the north of the Himalaya chain, from two small streams which pass the town of Ladak. They fixed the source of the Indus in the Bolor Mountains, one of the cross ridges which run N. and S. from the main Himalaya ridge. The British in India, with all their characteristic ardour in the cause of science, have corrected those errors of the Chinese geographers, having ascertained the source of the Ganges to be not on the N., but on the southern side of the Himalaya Mountains. The extent and bearing, and the vast elevation, of many of the highest peaks of this northern barrier of Hindustan, have also been fixed by the accurate observations of Lieutenant Webb and other officers. From the embassy of Elphinstone into Afghanistan we have received more full details of that country; and the course westward of the great Himalaya chain has been accurately traced, as well as the upper course of the Indus, through the source of that river is still imperfectly known. The missions of Turner into Bootan, of Kirkpatrick and Buchanan into Nepaul, and the embassy of Major Symes and Dr Buchanan to the court of Ava, and of Mr Crauford, who resided in the character of ambassador at that court, and whose works have thrown great light on the commerce and manners of Asia, have contributed materially to illustrate the geography of those countries. Of the vast regions of Tartary to the W. of China, and under its dominion, we know little except from the earlier travellers and missionaries, and from the accounts published of the journeys of the Russian embassies through these countries. The travels of Huc, Gabet, and Puch, have made some additions to our knowledge of Tartary and Tibet; and the hitherto proverbial jealousy of the Chinese authorities in regard to the intrusion of foreigners into their western dominions, may perhaps now be expected to give way to a more tolerant policy.

Asiatic commerce.

Asia, notwithstanding the wars by which it has been desolated, was from an early period the seat of commerce and of wealth. The eastern countries of Hindustan and China appear to have preceded Europe in civilization and industry, and, independent of that diversity of natural productions which is the foundation of trade, they had cultivated many arts and manufactures which were unknown in the Western World. Asia accordingly abounded in many precious commodities which could not be produced by the ruder industry of Europe. Thus China had its silk and porcelain; Hindustan its muslins, cotton, precious stones, and aromatics of all sorts; costus, bdellium, spikenard, ivory, tortoise-shell, pepper, &c. These were in general demand throughout Europe, where they could not be produced; and they were procured in exchange chiefly for bullion, which then, as in later times, was the great article of export to India; also for woollen cloths, wine, brass, lead and tin, glass, coral, female slaves, &c., all which commodities met with a ready sale in the markets of Hindustan. The staple commodity of China was silk; and the mode of producing this esteemed luxury being unknown in Europe, it was brought in large quantities, either by the caravans or by the annual fleets, to Alexandria, at that time the great commercial mart of the East, and was thence sent to supply the demand at Rome, where it sold at one time for its weight in gold; but, owing to the high profit, caravans began to travel so regularly to China, that the supply increased with the demand, and the price was reduced. Between the sixth and the seventh centuries Eastern Asia was robbed of this precious monopoly by the art of two Persian monks, who contrived, in a hollow cane, to transport the eggs of the silk-worm from China to Europe, where they were hatched by means of heat, and the race quickly propagated; and one great link of commerce between China and Europe was in this manner broken. The trade of Asia was interrupted by the irruption of the barbarians, who invaded and finally subverted the Roman empire; but the moment the storm was past, commerce resumed its quiet course. Constantinople, the eastern capital of the empire, was still the centre of luxury and trade; as were also such parts of the Roman territory as had not been swept by barbarian invasion; and with those places the caravans still traded, shaping their course as they best could to avoid the distractions of the interior. Farther to the east the khalifs who reigned at Baghdad encouraged science, commerce, and the arts; and the extensive country through which the Oxus and the Jaxartes flowed was the seat of a flourishing commerce and of many opulent cities. Besides Bokhara, still a great city, Balk, Samarcand, Cosh, and others in the valley of the Oxus and the Jaxartes, numerous splendid cities are enumerated which are scarcely known to Europeans. To the east of the great range of mountains which takes a direction from the main Himalaya ridge, the country of Cashgar contained Cashgar its capital, and Khoten, which were both large, populous, and wealthy. Those countries served as the connecting link between India and Europe, and the resting-place of the caravans, which there collected in great force, and prepared for their journey to China across the great eastern desert, or for a more southerly course through the country of Tibet. The armies of Zinghis Khan in the thirteenth, and of Tamerlane in the beginning of the fifteenth century, laid waste this highly-cultivated and flourishing region. But those conquerors were not the enemies of commerce, and the surplus produce of India still reached Europe, though by a route rendered more difficult and dangerous from the desolation of the intervening countries. But the effect produced on the trade of Asia in the East by the encroachments of barbarism, and by the disorders in the interior, was more than counterbalanced by the growing civilization of Europe. About the beginning of the fourteenth century, the darkness which had so long covered the western world began to dispel, and the Italian cities of Venice, Genoa, and others, had already made advances in letters, science, and commerce. The costly articles of Asia, her rich stuffs and precious aromatics, were now required to answer the grow-

Asia.

ing demands of luxury and wealth; and the produce of India, imported into Alexandria through the Red Sea, was thence brought into Italy by the nobles of Venice and Genoa, who were all engaged in trade, and was diffused in smaller quantities all over Europe. The Italian states were enriched by this lucrative traffic, which only ceased with the discovery of the maritime route to India by the Cape of Good Hope. From this period the trade between Asia and Europe took a different direction. The commodities of India and China were transported to Europe directly by sea; and neither Alexandria nor the other ports of the Red Sea or of Italy were any longer the depositories of the Eastern trade. The Portuguese, always distinguished by their ardour for maritime discovery, were the first adventurers in the Asiatic seas. In the course of the sixteenth century the English and Dutch appeared as their competitors; and with the growing wealth of those countries the trade to the East rapidly increased. The commerce of Asia may therefore be distinguished into the following branches:—*1st*, The inland trade of China, Hindustan, Burmah, &c., with Turkey, the eastern countries of Europe, and with the intervening countries of Persia, Balk, Bokhara, and the regions of the Oxus; also, by a different route, the trade with Russia and the N. of Asia. *2dly*, The maritime trade, including the coasting trade and the trade to the Eastern Archipelago, and the great trade to Europe and America, in which, from the progress of wealth and luxury, there is a great consumption of Asiatic produce.

Inland commerce.

The inland trade of Asia is carried on by caravans, or large bodies of merchants, who travel together for the sake of security through those parts of the country which are disturbed by predatory tribes. It is only from the southern countries of Asia, such as Hindustan, China, the Burmese countries, Tibet, and the western countries of Persia, Afghanistan, Bokhara, and the regions of the Oxus and the Jaxartes, that Europe can derive any supply of valuable commodities; and all this trade, from whatever quarter it comes, must flow in its progress to Europe through the countries that lie between the Persian Gulf and the Caspian Sea; as the caravans could not, without inconvenience and danger from wandering tribes, pass to the north of this sea or the Sea of Aral; and accordingly, though an annual caravan is sent from Astracan to Khyvah and the countries on the Oxus, the chief trade with Russia is by sea to the port of Mangalshuck, and thence to Khyvah and Bokhara. The Russians have also begun to trade with Persia from the Caucasian province of Georgia, of which Tiflis, the capital, has, from a wretched collection of wooden huts, been rapidly improved, under the protecting influence of a European government, into a respectable and wealthy town, the future emporium, as may be anticipated, of this growing trade. The caravans from Constantinople and Syria proceed through Asia Minor and the northern or southern provinces of Persia, according as their ulterior route is through Afghanistan and the Punjaub into Hindustan, or to Tibet and China, or the more northern districts of Balk, Bokhara, and the country of the Oxus and the Jaxartes. Bokhara though reduced to desolation by Zinghis Khan, is still one of the largest towns of the East, its population being estimated by Burnes at 160,000. It is also a great commercial mart; and the caravans which come from the west, passing along the southern shore of the Caspian Sea through the Persian province of Astrabad, a most luxuriant and fertile country, arrive successively at Balfroosh, Ashruff, Astrabad, Mushed, Serrukhs, Merve, formerly the capital of the Seljook sovereigns, but now surrounded by deserts, and at Bokhara. From this great centre of commerce they proceed north-eastward about 400 or 500 miles to Khojend and Kokaun, the former a large city, said to contain 30,000 houses; and crossing the Bolor range of the Himalaya Mountains, they arrive in the Mahometan states of Kashgar and Yarkund, 600 miles E. of Kokaun, passing some towns on the way, of which Ush is the most important, being a trading and populous town. Those two latter states lie within the precincts of the Chinese authority, where the most exact order is enforced; and they are fertile, rich, and well cultivated. The town of Cashgar is said to contain 20,000 houses, and to be thronged with strangers from all parts of Asia. Yarkund is also wealthy and populous. So strict a police is maintained by the Chinese authority, that, according to the information given to Fraser,[1] a single traveller may traverse the whole territory as safely as a large caravan. From Kashgar there is a constant intercourse through Chinese Tartary, along the edge of the great central desert, with China, though we know little of the intervening countries beyond what we learn from the accounts of the early missionaries. Besides this eastern trade, and the trade westward along the southern shore of the Caspian, two caravans, consisting of 4000 or 5000 camels each, proceed to Astracan by Khyvah, round the northern shore of the Caspian Sea. The imports from Russia into Bokhara are iron, steel, copper, brass, quicksilver, vermilion, coral, hardware, plated goods, gold and silver embroidery, copper wire; furs, the broad cloths and cotton manufactured goods of Britain, Germany, and France; refined sugar, cochineal, paper, and a variety of rich goods, which, from this great commercial depot, are diffused far and wide over Central Asia. Russia receives in exchange black lamb-skins, certain manufactures of cotton and silk imported from Persia, antique gems and coins, lapis lazuli, rubies, and turquoises, which are received from the southern country of Buducksha, where there are famous mines of these precious stones. From Cashgar, Yarkund, and the side of China, Bokhara receives large quantities of tea, the great modern staple of the China trade, porcelain and China ware, and the various manufactures of China; and in return sends turquoises, coral, sheep, lamb, and fox skins, and furs, &c. From Persia shawls are imported, and woollen goods from Kerman; silk stuffs from the cities of Yezd and Ispahan; gold and silver embroidery, copper ware, loaf, candy, and raw sugar; Hamadan leather; and turquoises, of which there are mines in Persia; and, in return, black sheep and lamb skins are sent, which are in great request, to be manufactured into black caps; camblet made of camel's hair, coarse coloured silk handkerchiefs, lapis lazuli, indigo from India, cochineal, tobacco, chintzes from Masulipatam, and cotton manufactures. Slaves form a staple article in the commerce of Bokhara, and also of Khyvah. These are made prisoners by the disorderly tribes of Asia, the Koords, Turkomans, &c., in the course of the wars in which they are constantly engaged; and they are carried to the great slave markets of Bokhara and Khyvah, where they are exposed for sale like cattle. The balance of trade is always in favour of Bokhara. Money is consequently in great plenty and cannot be imported with a profit into this trading city. The Russian caravans, as they journey round the N. shore of the Caspian Sea, are frequently attacked by the Kirgeesh and Cossack tribes, and prisoners are carried off and sold into slavery. Fraser was assured that the number of Persian slaves in Khyvah and its dependencies exceeded the male population of these countries, and amounted to 150,000; and that, according to inquiries set on foot by the Empress Catherine, there were in Bokhara no less than 60,000 Russian slaves.

The commerce of the west with the southern countries of Asia, namely, Kabul or Afghanistan, Cashmere, and India, passes through Persia by a different and more southerly route, namely, by Cashan, Yezd, which is the seat of rich silk manufactures, a great entrepôt of commerce, and a conve-

[1] *Narrative of a Journey into Khorassan*, Appendix.

nient resting-place for all the caravans, both from the East and other quarters; through Furrah and Herat, on the frontiers of Persia, famed for its rich manufactures of silk stuffs, a great channel of communication between the East and the West, and also an entrepôt of all the richest productions from Kabul, Cashmere, and India on the one side, and from Bokhara, Persia, Arabia, Turkey, and even Europe on the other. From Herat the route continues through Furrah and across the river Helmund and the ranges of the Paropamisan Mountains, to Candahar, a journey of about 800 miles; thence to Kabul, Peshawur, and the countries on the Indus, and across extensive sandy deserts to the rich valley of the Ganges, whence by this river, there is an easy access to Bengal and to Central India. There are various other routes by which the commerce of Asia, concentrated within the comparatively narrow boundaries of the Caspian Sea and the Persian Gulf, diverges in its progress eastward to the N., as well as to the S. From Bokhara there is a mountainous route into Little Tibet, and thence through Tibet into China; besides other more sequestered and difficult roads, through glens and mountains, where the only mode of transport is on the backs of asses and mules.

Persia, from its central situation between the East and the West, is not only a great entrepôt of Asiatic trade, but, though on the whole rather a poor country, it still contributes some valuable productions to the commerce of the East. It has long been famed for its abundant produce of raw silk, of cotton, and of wool—that of the province of Kerman especially being so valuable for shawls that it rivals in some respects that of Cashmere; of fruits, turquoises, tobacco, grain, &c. Almost all the principal towns of Persia, such as Kashan, Ispahan, Yezd, Tabreez, Kerman, Herat, &c., excel in the manufacture of silks, cottons, woollens, fine carpets, &c.; Kerman also in the manufacture of shawls; and others in that of cutlery, arms, &c. These are its chief exports to other countries, in exchange for their manufactures or produce. To India Persia sends raw silk, carpets, Kerman shawls, dried fruits, tobacco, horses—in which there is a considerable traffic, swords, &c., and specie to make up the deficient balance. The imports from India are cotton goods, as chintzes, sent from Masulipatam by sea to Bushire, whence they reach the interior of Persia, and are thence carried eastward into Kabul and the countries on the Indus; the same article from Moultan, Lucknow, Delhi, &c.; some muslins, indigo, spices, sugar, and sugar-candy, in large quantities; gold and silver stuffs and brocades from Benares; precious stones, Cashmere shawls, iron, lead, copper, &c. Many of these articles, namely, Cashmere shawls, spices, indigo, muslins, &c., are carried through Asia Minor by a long land carriage to their final destination in European Turkey, and are found, along with the lamb-skins of the no less distant Bokhara, in the bazaars of Baghdad and Constantinople.[1] To those countries Persia exports also every article of her own rude and manufactured produce; coarse fabrics, both of silk and cotton, for the consumption of Asia Minor; and many heavy articles, such as grain, rice, tobacco, salt, coffee, cotton, &c.; besides fine silks, brocades, and prints, which are exchanged in Turkey for European goods brought through the countries of the Levant, namely, broad and narrow cloths, cassimeres, cotton goods, chintzes, muslins, veils, silks, satins, French brocades and embroidered goods, imitation shawls, cutlery of all sorts, glass, &c., and a considerable quantity of gold and silver bullion. Persia imports coffee and pearls from Arabia, in exchange for wheat, dried fruits, and cloaks. The mountainous country of Afghanistan, on the southern declivity of the Himalaya ridge, and the country on the head streams of the Indus, export to India horses and ponies bred in Tartary, fur, shawls, Moultan chintz, madder, assafœtida, tobacco, and dried and other fruits, such as almonds and pistachio nuts. The imports from India are coarse cotton cloths, worn by the common people of this country, and also in Tartary; muslins and other fine manufactures, silken cloth and brocade, indigo in great quantities, ivory, chalk, bamboos, wax, tin, sandal-wood, almost all the sugar which is used in the country, and spices from the Malabar coast, through Kurrachee and other parts of Sinde, and thence to Kabul and Candahar. The Indian cloths, shawls, chintzes, and also the indigo, are exported to Bokhara, from which are imported the broad cloths, cutlery, and hardware of Europe, received from the Russians, and finally consumed in Kabul and the countries of the Indus, loaded with the expenses of a land journey across nearly half the globe.

In the E. of Asia, China has from the earliest times been the seat of wealth and of an extensive trade. The Chinese have been always noted for their industrious habits, and the country has from time immemorial abounded in the most valuable produce and manufactures. These were sent westward in the caravans to Asia Minor and into Europe, or they were transported by sea to India, and carried thence by the European fleets to the Red Sea. The same commerce is still continued, and China exports its produce of woollens, silk, and satin; tea in small boxes of thin lead; china, porcelain, raw silk, cochineal, crystal, gold dust, golden ingots, and silver with the Chinese stamp. These are sent through Chinese Tartary into the countries on the Oxus, and also to Cashmere, Kabul, and the countries situated on the southern declivity of the Himalaya Mountains. Regular caravans of horses and ponies, no other animal being fit to travel through those mountainous districts, set out from Cashmere, and from Peshawur, the capital of the Afghan country of Kabul, and a considerable commercial resort, to make their way through Chinese Tartary with goods imported from India and Persia. China carries on also an interior trade to a considerable extent with Russia by the frontier town of Maimatchin, in which European goods and furs are received in exchange for tea, silk, and other articles of Chinese produce and manufacture.

Maritime commerce

In addition to her internal trade, Asia maintains an extensive intercourse by sea with Europe, America, and with Egypt and all the countries on the Mediterranean. A great trade is also carried on from Hindustan and China to the Asiatic Archipelago, and the trade of the Asiatic islands with each other is of great importance. It appears that those islands were at a very early period the seat of commerce; and the learned researches of Europeans have brought to light, in some of them, the monuments of ancient civilization. Sumatra was the seat of the Malay empire, Java of a Hindu state; and the Celebes were inhabited by the Bugis, a race of expert navigators and merchants. The productions of these islands, and of the Moluccas and Borneo, namely, spices, aromatics, and gold, entered into the commerce of the ancient world, and were imported into Rome through Egypt. In later times, about the ninth century, the Asiatic Archipelago was visited by the Arabs and the Chinese, while the adventurous Malays frequented the coasts of Asia, and even of Africa, and particularly the African island of Madagascar. When these islands were visited by Europeans, about the fifteenth century, Malacca, Acheen, and Bantam were the great marts of the Eastern Archipelago, where the rich produce of Sumatra, Borneo, and the Moluccas, conveyed in the small trading craft of the country, was exchanged for that of India and China.

[1] Elphinstone's *Cabul*; Kinneir's *Geographical Memoir of Persia*; Fraser's *Travels in the Persian Provinces around the Caspian Sea*, Appendix, p. 364.

The Portuguese fixed on Goa, on the Malabar coast, as the capital of their Eastern settlements; and they afterwards selected Malacca as a central station for protecting and extending their intercourse with the neighbouring nations. The Dutch chose Bantam, and afterwards Batavia, situated midway between Hindustan and China, as the centre of their commercial settlements. The situation was most advantageous, and the port was soon frequented by vessels from China and Japan, Tunkin, Malacca, Cochin China, and the island of Celebes. But the great and flourishing trade of Java was crushed under the colonial monopoly of the Dutch, and under what Sir Stamford Raffles terms "the short-sighted tyranny of a mercantile administration." The conquest of Java by the British in 1812 put an end to this thraldom, and the great trade of the Asiatic Archipelago began to centre in Batavia, which was fast rising into a great commercial emporium; all the articles which were the exclusive produce of the Eastern islands being collected at its principal ports for re-exportation to India, China, and Europe. Since Java was restored to the Dutch, the free port of Singapore, established by the British, is the centre of a great trade, and is frequented by the Chinese in their junks, and by all the other navigators of those seas with the produce of their respective islands. The Chinese take back with them the nests of a certain species of bird, which are esteemed a great luxury at their tables, and sell, it is said, for their weight in silver; biche-de-mer or tripang, a dried sea-slug, also used in Chinese dishes; Malayan camphor, the exclusive produce of Sumatra and Borneo; the tin of Banca, the spices of the Moluccas, opium, indigo imported from Hindustan; gold and silver, the first collected in Sumatra, Borneo, and some of the other islands. The maritime country trade of the Asiatic islands is carried on chiefly by the Chinese in their junks and brigs, by the Arabs in square-rigged vessels, and by the Bugis, the inhabitants of Celebes, who are all bold and expert navigators.

From the E. the annual fleet of Chinese junks arrives with the favourable monsoon among these islands, from Canton, Amoy, and other provinces, with cargoes of teas, raw silk, silk, piece-goods, and innumerable minor articles, for the use of the Chinese, who are settled in great numbers here, and are distinguished by their shrewd, intelligent, and industrious habits. The Chinese extend their voyages to Sumatra, the Straits of Malacca, and eastward as far as the Moluccas and Timor, collecting edible bird-nests, biche-de-mer, and other articles of which Java is the great entrepôt. Java is also a great depot of European goods; and the people being rather industrious cultivators of their fertile island than mariners or traders, it exports rice, a variety of vetches, salt, oil, tobacco, timber, brass-wire, and its own cloths, and a considerable quantity of European, Indian, and Chinese goods, in exchange for gold dust, diamonds, camphor, benjamin, and other drugs; edible bird-nests, biche-de-mer, rattans, bees-wax, tortoise-shell, and dyeing woods from Borneo and Sumatra. The rice and other productions of Java are exchanged for spices and pungent oils of the Moluccas, and for the tin of Banca. The natives of Celebes are famed for the manufacture of a particular species of fine cloths, of a very strong texture, which are in great request, and, along with spices, wax, and sandal-wood, are exchanged for the produce of Sumatra, Borneo, and Java, whence they are exported to China. The Bugis have a large share of the carrying trade of the Asiatic Archipelago; and they bring the produce of the Moluccas, and of Borneo and Sumatra, to Java and the other islands, and receive in exchange tobacco, rice, and salt, from Java, besides opium, iron, steel, European chintzes, and broad cloths and Indian piece goods, with which they return eastward during the south-west monsoon.[1]

The eastern countries of Asia, viz. India and China, as we have already stated, have from time immemorial been famed for certain manufactures, such as silks, cambrics, muslins, &c., as well as for other products peculiar to the climate, viz. spices, precious aromatics, medicinal herbs, &c. These were always in great demand in Europe, while the produce of Europe was not wanted in Asia. From the rude state of industry among the Western nations, they had nothing to offer in exchange for the finer manufactures of India, and still less could the soil of Europe yield any equivalent for the more genial produce of Eastern climes. Hence the great article of export in those times from Europe to Asia was always bullion, the instrument of exchange all over the world. Bullion could only be procured by an exportation of European produce or manufactures at such low prices as to insure a sale; and the loss on such transactions must have been made up to the merchant by the high price of Asiatic goods. The ancient monopoly of silk secured to Asia a favourable balance of trade with Europe, bullion being the only article with which it could be purchased. Notwithstanding the introduction of the silk manufacture into Europe about the sixth or seventh century, the commercial pre-eminence of Asia still continued, and bullion was the chief article of export to the East. Throughout the interior of Asia this superiority remains to the present day; and a continual stream of bullion flows from the Bosphorus eastward through Asia Minor and Persia into Hindustan, and is finally dispersed in the great ocean of the Chinese currency. Bullion is also the principal article sent from Arabia to India in exchange for Indian goods.

But a great revolution has taken place in the trade between Asia and Europe, and especially with Great Britain. Europe is now in a condition to offer an equivalent in manufactures for the produce of Asia; goods of various kinds are sent in exchange for those of India; and from Great Britain remittances in bullion have nearly ceased. So prodigiously has the price of goods been lowered by the use of machinery, that the cotton wool of India is now imported into Britain, and, after being manufactured, is re-exported to the place of its growth, and sold at a lower price than the same goods from the loom of the Indian workman, though it is loaded with the expense of a double voyage across half the globe. The goods of the European manufacturers are poured into Asia through all its seaports, and reaching the interior on the backs of mules and asses, often after a journey of several thousand miles over deserts and mountains covered with perpetual snow, they are sold cheaper than the same articles by the native workmen. The woollen manufactures of Yorkshire, the cotton goods of Manchester and Glasgow, French cloths, and German linens, are dispersed all over India, and even partially in China; they are found in the bazaars of Bokhara, Samarcand, and Cashgar, and are carried eastward by the caravans into the wilds of Tartary. The natural productions of Asia, namely, spices, rich aromatics, dyes, and other rare luxuries of tropical climates, will always be in demand in Europe; and the monopoly of tea by the Chinese gives them the command of the European markets. Tea has now almost become one of the necessaries of life, and it travels for a market across half the globe. It is the great commercial link between Europe and China, from which, like the precious produce of silk in ancient times, it can only be procured. But the improved industry of Europe supplies, as already observed, an equivalent in woollen and cotton goods for this highly-prized luxury. Since the expiry of the charter of the East India

[1] Raffles' *History of Java*: Marsden's *Sumatra*.

Company in 1834, the trade has been thrown open to all classes of British subjects, and our merchants can now freely trade to all places accessible to Europeans to the E. of the Straits of Malacca. During the short time that has elapsed since then, the increase of the exports and imports have fully realized the expectations held out by those who opposed the Company's monopoly. See HINDUSTAN. (H. M.) (W. P—E.)

ASIA MINOR. From the unsettled state of this country, once the seat of early civilization and the cradle of the fine arts, it is now comparatively imperfectly known, and the accounts left us by ancient writers are very meagre and unsatisfactory. It is, however, of perhaps greater interest to the geographer, the historian, and the antiquary, than almost any other country. It everywhere abounds with relics and monuments of antiquity, all tending more or less to throw light upon the history of the human race. It may be true that Asia Minor was only of secondary importance in the palmy days of Assyria and Egypt,—when science, literature, and arts flourished in Greece, or when Rome sat mistress of the world; but these rose to eminence for a short time, only to fall into a greater depth of barbarism, whereas it has maintained a greater or less degree of importance from the first dawn of history to the present time. But even apart from its historical interest, the country itself presents much to recommend it to notice. The grandeur and picturesque beauty of its scenery renders it at least equal, if not superior, to any country of Europe, while its extreme productiveness, coupled with the number of its excellent ports and other advantages, give evidence, that under a more favourable system of government it might become a place of importance in a commercial point of view; but at present its imports are subject to very heavy and arbitrary taxes, and almost every branch of industry is paralyzed by the still more ruinous system of monopolies.

When the descendants of Noah were, from their numbers, obliged to disperse themselves over the earth, the family of Lud, one of the sons of Shem, is supposed to have been the first to people the wilds of Asia Minor, and to have at length settled on the banks of the Hermus. The traditionary Lydus, the eponymous king of the Lydians, is supposed to be the same with Lud, and his grandfather Manes is probably the Noah of Scripture. It is not our intention, however, to follow out here the history of the country, as that will be found in other parts of the work. Suffice it to say, that Asia Minor was the theatre of the earliest remarkable events recorded in profane history, as the Argonautic Expedition, the Trojan War, in which the gods are said to have descended from Olympus and joined battle with mortals; the conquests of the Persians, the overthrow of their empire by Alexander, and the settlement in this part of Asia of his successors. It subsequently fell under the Roman sway, and suffered severely in after ages in the wars of the Saracens, the Turks, Tartars, &c. It is also intimately connected with the early history of Christianity, and the first Christian churches were planted here.

From the earliest times till after the establishment of the Roman power in Asia Minor, that country, or a part of it, went under the general name of Asia. Homer and others apply this term to the valley between Tmolus and the Caystrus. When the Romans extended their conquests beyond the peninsula, they divided their Asiatic territory into *Asia intra Taurum*, and *Asia extra Taurum*. The term Asia Minor seems to have been adopted about the fourth century of our era, and was applied to that peninsula of Asia extending westward from an imaginary line drawn from Trebizond to the Gulf of Scanderoon. It comprehended Mysia, Lydia, Caria, Lycia, Pisidia, Cilicia, Bithynia, Paphlagonia, Pontus, Phrygia, Galatia, Lycaonia, Cappadocia, and Armenia Minor.

Most of the works of the ancient geographers and historians on this country are now lost, with the exception of Strabo, Pliny, Ptolemy, Stephen of Byzantium, and a few others. Accounts of several military expeditions into the country are, however, extant, as Xenophon's account of the expedition of Cyrus the younger; Arrian's history of the Asiatic expedition of Alexander the Great; the history of the Roman wars in Asia, by Polybius, Livy, and Appian, particularly Livy's account of the Marches of the Consul Manlius through Phrygia, Pamphilia, Pisidia, and Galatia, to Ancyra; Anna Comnena's account of her father Alexis Comnenus' expedition against the Turks. Among modern travellers in this country are Tavernier, Tournefort, Pococke, Niebuhr, Beaufort, Kinneir, Richter, Leake, Keppel, Arundell, Fellow, Texier, Hamilton, Chesney, Ainsworth, &c. The work, however, which promises to throw most light upon this interesting country is that by the recent traveller Tchihatcheff, entitled *Asie Mineure, Description Physique, Statistique, et Archeologique*. The first volume has lately been published, and is devoted to the physical geography; the second is to treat of the meteorology, botany, and zoology; the third of the geology; and the fourth is to give a statistical and archæological account of the country.

The peninsula of Asia Minor is the most western territory of Asia, and extends northward from the Mediterranean to the Euxine, and eastward from the Grecian Archipelago to the banks of the Euphrates. Its length from E. to W. is nearly 600 miles, and its breadth about 360, lying between Lat. 36° and 42° N., and Long. 26° and 40° E. It is divided into the pashaliks of Anatolia, Livas, Karamania, Isthil, Adana, Marash, and Trebizond. The principal towns are Smyrna, Trebizond, Brusa, Angora, Konieh, and Kaisaryeh.

It may be described as an elevated table-land, consisting principally of a succession of extensive plains, frequently furrowed by deep valleys, and intersected by lofty chains of mountains. The limits of this extensive upland, containing these plains and valleys, are marked by an elevated and almost continuous chain of mountains, round which, at a lower level, a succession of narrow plains border the shores of the Mediterranean and Black Seas. The Taurus mountain chain extends from E. to W., near its southern coast, rising frequently to the height of 8000 or 10,000 feet; and along the northern coast is another chain rising to the height of 6000 or 7000 feet, and comprising Mount Olympus and Mount Ida of antiquity. On the S.E. are the mountain chains of the Anti-Taurus, the loftiest point of which, Arjish Tagh, attains the height of 13,000 feet.

The coast of Asia Minor is deeply indented by bays and gulfs, particularly on its western and southern sides. Along the western coast there are numerous deep and well-sheltered harbours, as well as in that part of the southern belonging to Lycia, while those of the northern coast are all more or less exposed to the action of the winds. Asia Minor contains several lakes, some of which receive streams but emit none, evaporation being sufficient to preserve their level. The *Tuzla*, or salt lake of Koch-Hissar, situate nearly in the centre of Asia Minor, is stated to have only a circumference of 30 leagues, although it is 50 miles in length. Its waters are so salt that no fish exist in it; and birds are said to avoid it, as when they alight on it their plumage instantly becomes incrusted with salt so as to impede their flight. Wood thrown into it is immediately incrusted with salt. Vestiges of a causeway that once crossed it are nearly concealed by a coating of salt; and in some places the bottom is a solid mass of muriate of soda. This salt is collected at four places, and is a government monopoly. Its

surface is 2500 feet above the level of the Mediterranean. In the language of the adjacent district it bears the names of *Tuz-choli* (salt desert) in summer, when partially dried up; *Tuz-Goli* (salt lake), *Agi-goli* (bitter lake), or *Koch-Hissar-goli* (lake of Koch-Hissar.) Southward of this lake, towards the Gulf of Adalia, are several other lakes; one of these, *Egerdir*, is a fine fresh-water lake, 30 miles long, surrounded by lofty branches of the Taurus, clothed with forests. The lake of *Beg-shehr*, also fresh, is about the same size, and discharges its superfluous waters by a considerable stream into the lake of *Seidi-shehr*, or *Soghlah*, which has no visible outlet, but is fabled to have a subterranean passage through the chain of the Taurus. The other lakes deserving notice are those of *Ak-shehr*, *Eber-Ghieul*, *Ak-Ghieul*, near Eregli; *Mangas-Ghieul*, and *Ulubad*, or Apollonia, to the S. of the Sea of Marmora.

The principal river of Asia Minor is the *Kiril-Irmak*, which has a tortuous course of above 400 miles through the eastern part of that region, and falls into the Euxine. It is the celebrated Halys of antiquity. The other principal streams falling into the Black Sea are the *Jehil-Irmak*, the Jorukh, and the Sakaria; while the Caïcus, the Hermus, Cayster, and Mæander with its three affluents, now individually the *Grimalki*, Sarabat, and Meinder-su, pour their waters into the Mediterranean.

The mountain ranges of Asia Minor seem to be principally composed of limestone reposing on granite, quartz-rock, and schists, with secondary formations on their flanks; in the valleys, tertiary and lacustrine deposits, ancient and modern igneous rocks, and recent sedimentary accumulations. The micaceous schist and associated rocks, however, form a great part of the mountain chains which intersect the western portion of the peninsula. Tertiary lacustrine formations occur in almost every valley, and secondary deposits, with organic remains, are found in several places. Trap-rocks are of frequent occurrence, and trachyte is abundant in the western part of the country. About 90 miles eastward of Smyrna is the district of Katakekaumene, or burnt-up country, about 19 miles in length and 8 in breadth. It consists of mounds of erupted rocks, referable to two epochs; the older cones are low and flat, their craters only marked by slight depressions, or have entirely disappeared; the more recent ones, three in number, still retain their forms unaltered, though they have been extinct for more than 3000 years. The former are covered with vineyards which produce the Katakekaumene wine, celebrated since the days of Strabo.

The climate in the lower parts of the country bears a considerable resemblance to that of Southern Europe. The soil, except in the rocky districts, is very fertile and well watered. A large portion of the surface, particularly in the territory bordering upon the two seas, consists of a fine alluvial soil, covered with rich herbage, or the finest grain crops. The mountain ranges are in many places mantled with extensive forests of pine, beech, chestnut, walnut, plane, and mulberry, while the plains and valleys produce oranges, lemons, grapes, figs, and olives.

The chief productions of the country are silver, copper, iron, lead, and alum; grapes and other fruits; grains, silk, cotton, hemp, flax, tobacco, opium, saffron; madder, mastic, and other gum resins, galls, skins, hides, wool, goats' hair, leeches, sponges, wax, honey, salt, and some wine. The imports are confined chiefly to coffee, sugar, spices, cutlery, and cloths.

The principal inhabitants of Asia Minor are Osmanli, or Othman Turks. In the interior are several nomade tribes of Turkomans, Kurds, and Yorukhs; of these the Turkomans are the most numerous and civilized. Like the Osmanli, they are a branch of the great Turkee family, and speak a kindred dialect. In summer they live in tents, but in winter are generally inhabitants of villages. They possess large herds of camels, buffaloes, sheep, and goats. They have also a fine breed of horses, which they dispose of, with flesh, butter, and milk, to the inhabitants of the adjacent towns and villages, in exchange for money, arms, and articles of clothing. Their women spin wool and weave handsome carpets. Each camp or village is under a chief, whose power is regulated by custom and the habits of his tribe. They pay to the pasha of the province they inhabit a certain rate per cent. for the privilege of pasturage in the uncultivated lands. The Kurds are inclined to pillage travellers, and inhabit the wilder parts of the country. The Yorukhs live in tents throughout the year, among the mountains generally; and when near towns they cultivate a little ground, and are usually the charcoal burners of the district.

ASIATIC SOCIETIES. Numerous associations of learned men have, within a comparatively modern date, been formed for the purpose of adding to our knowledge of Eastern countries in the various departments of science and literature. The oldest society of this kind was founded by the Dutch in Batavia. Its transactions, published at Batavia from 1780 to 1833, form 15 volumes. The next was the *Royal Asiatic Society of Bengal*, founded at Calcutta in 1784 by Sir William Jones. Its transactions from 1788 to 1832 appeared under the title of *Asiatic Researches*, and afterwards as the *Journal of the Royal Asiatic Society of Bengal*, to which the accomplished editor Mr Prinsep contributed his researches in Indo-Bactrian and Persian numismatics.

In 1823, the *Royal Asiatic Society of Great Britain and Ireland* was established at London by Mr Colebrooke, assisted by Ouseley, Staunton, Wynn, and other eminent orientalists. The literary societies of Bombay and Madras were subsequently incorporated as branches of this society. Since 1833, its transactions have been published in the society's journal, published quarterly, of which vol. xiii. appeared in 1852. To this journal Major Rawlinson has contributed his valuable researches on the ancient cuneiform inscriptions of Persia. This society possesses a valuable library and museum. Connected with it is the *Oriental Translation Committee*, instituted in 1828, which has published versions in English, French, and Latin, of many valuable oriental works, as well as several original texts.

The *Société Asiatique* of Paris was founded in 1822, by the distinguished oriental scholars Silvestre de Sacy, Abel-Remusat, Saint Martin, Chézy, Klaproth, Degérando, &c. Its transactions appeared monthly under the title of *Journal Asiatique*, until January 1828, when it took the name of *Nouveau Journal Asiatique*. This society has published many important works. It holds an annual public meeting, and has a good museum. An oriental institution, with chairs of Oriental languages and a museum, is supported at St Petersburg by the government. In Germany there is the *Deutsche Morgenländische Gesellschaft*, of the journal of which 6 vols. have appeared at Leipzig. The *Zeitschrift für die Kunde des Morgenländes*, begun at Göttingen in 1837, is now edited at Bonn, by the eminent orientalist Lassen. The labours of German orientalists have also found a place in the well-known collection entitled *Mines de l'Orient*.

The *American Oriental Society* issues a journal, of which 2 vols. have appeared.

ASIARCHÆ (termed by St Paul, *Chief of Asia*, Acts xix. 31) were the Pagan pontiffs of Asia, chosen to superintend the public games, which they did at their own expense. They were always persons of high consideration.

ASIENTO (a Spanish word signifying a *seat*, a *contract*), in *Commerce*, was used to denote a treaty between the king of Spain and other powers, for importing negroes into the Spanish dominions in America.

ASINARA, a small island of Italy on the western coast of Sardinia, with good coral fisheries. Long. 8. 15. E. Lat. 41. 5. N.

ASINIUS POLLIO, a Roman consul and orator, who distinguished himself under Augustus by his exploits and literary works. He is frequently mentioned with praise by Horace and Virgil, and is said to have collected the first library at Rome. He died at Frascati, at eighty years of age, A.D. 4. None of his works are extant.

ASKEATON, a small town of Ireland, county of Limerick, on the river Deel, two miles from its junction with the Shannon. It was founded by the Desmonds, and has remains of a fine Franciscan house, and a castle. Pop. in 1851, 1957.

ASKERN, a place six miles from Doncaster in Yorkshire, noted for its sulphureous springs.

ASKEW, or ASCUE, ANNE, one of the numerous victims to the cause of the Reformation in the year preceding the death of the tyrant Henry VIII., was a lady of great merit and beauty, of a good family in Lincolnshire, and in correspondence with Queen Catherine Parr, and the chief ladies of the court. She had studied the Scriptures, and denied the real presence in the Eucharist, for which a bigoted husband expelled her from his house. On coming to London she was arrested, and interrogated by Chancellor Wriothesley and Bishop Bonner; at the instigation of whom, under threats of torture, she signed a qualified recantation. She was imprisoned, and wrote to the king, says Hume, "that as to the Lord's Supper she believed as much as Christ himself had said of it, and as much of his divine doctrine as the Catholic Church had required. But while she could not be brought to acknowledge the king's explications, this declaration availed her nothing, and was rather regarded as a fresh insult." She was most cruelly racked in the presence, and it was said by the hand, of the chancellor himself, in order to extort confession of those ladies about court with whom she corresponded. Her fortitude and fidelity probably saved the life of the queen and others. She disclosed nothing, although her limbs were so dislocated by the rack that when condemned to be burnt alive she could not stand, and was carried in a chair to Smithfield, where, on 16th July 1546, she underwent this terrible mode of execution with undaunted courage, along with four other victims of an atrocious tyranny.

ASKRIGG, a market-town and polling-place in the North Riding of Yorkshire, on the Ure, 15 miles S.W. of Richmond.

ASMODEUS. See ABADDON.

ASMONEUS, or ASSAMONEUS, the father of Simon, and chief of the Asmoneans, a family that reigned over the Jews 126 years.—Josephus, *Hist. Jud.*

ASNA. See ESNE.

ASOLO (ancient *Acelum*), a town of Austrian Italy, 18 miles N.W. of Treviso. It is well built and finely situated; has a cathedral and several other churches, with an ancient castle, and the remains of a Roman aqueduct, &c Pop. 3500. Long. 11. 58. E. Lat. 45. 50. N.

ASOPH. See AZOPH.

ASP, in *Natural History*, a poisonous kind of serpent. It is said to be thus denominated from the Greek ἀσπὶς, *a shield*, in regard to the manner of its lying convolved in a circle, in the centre of which is the head, which it exerts or raises like the umbo or umbilicus of a buckler. This species of serpent is very frequently mentioned by authors, but so carelessly described that it is not easy to determine which, if any, of the species known at present may properly be called by this name. It was with the asp that Cleopatra is said to have despatched herself, and prevented the designs of Augustus, who intended to have carried her captive to adorn his triumphal entry into Rome. But the fact is contested: Sir Thomas Brown places it in the list of vulgar errors. The indications of that queen's having used the ministry of the asp were only two almost insensible pricks found in her arm; and Plutarch says that the cause of her death is unknown. Naturalists now suppose the asp of the ancients to be a species of viper, either the *V. Echis* or *V. Cerastes* of Schlegel; and some suppose it to be the *Naja Haje.*

ASPARAGUS. See HORTICULTURE.

ASPARAGINE. See CHEMISTRY.

ASPASIA of Miletus, a celebrated courtezan who settled at Athens under the administration of Pericles. She was of admirable beauty; yet her wit and eloquence, still more than her beauty, gained her extraordinary reputation among all ranks in the republic. Her conversation was so entertaining and instructive, that notwithstanding her dishonourable profession, persons of the first distinction, male and female, resorted to her house as to an academy. It is said that she even numbered Socrates among her hearers. She captivated Pericles in such a manner that he dismissed his own wife, to make way for Aspasia, who, by her universal knowledge, irresistible elocution, and intriguing genius, in a great measure influenced the administration of Athens. She was accused of having excited, from motives of personal resentment, the war of Peloponnesus. The companions of Aspasia served as models for painting and statuary, and themes for poetry and panegyric. Nor were they merely the objects, but, as is said, the authors of some literary works, in which they established rules for the behaviour of their lovers, particularly at table; and explained the art of gaining the heart and captivating the affections.

ASPECT, in *Astronomy*, the position of one planet with respect to another.

ASPECTANT, in *Heraldry*, signifies face to face; as when two beasts or birds are borne opposite to each other in the shield.

ASPER (*Spiritus*), in *Grammar*, an accent peculiar to the Greek language, marked thus ʽ, and importing that the letter over which it is placed ought to be strongly aspirated, or pronounced as if an *h* were prefixed.

ASPERN, or GROSS ASPERN, a village of Austria on the left bank of the Danube, a few miles below Vienna. This village and the neighbouring one of ESSLING are celebrated as the scene of a tremendous conflict between the French army commanded by Napoleon, and the Austrians under the Archduke Charles. After two days hard fighting (21st and 22d May 1809), with great loss on both sides, the French were obliged to take refuge in Lobau, a small island in the Danube; but Napoleon speedily retrieved his losses on the field of Wagram.

ASPEROSA, a town and bishop's see of Turkey in Europe, situated on the coast of the Archipelago. Long. 25. 20. E. Lat. 40. 58. N.

ASPERMOUS (α, priv., and σπέρμα), in *Botany*, destitute of seed.

ASPHALTITES LACUS, or LAKE OF BITUMEN, so called from the bitumen which floats upon its surface. The Arabs call it *Birket Lut*, "the Sea of Lot." It is more familiarly known as the DEAD SEA, a name associated with many fables, and derived from a long standing belief that no creature could live in its waters, or within reach of its pes-

tiferous exhalations. It lies between Lat. 31. and 32. N. Long. 35. 40. E.

This celebrated lake is supposed to occupy the site of the ancient plain of Sodom and Gomorrha; and this belief may possibly have given rise to the idea of its deadly exhalation. It is, indeed, possible that when the volcanic agencies that appear to have torn and upheaved its rocky southern borders were in operation, such emanations may have taken place, but these have long ceased. Early in the Christian era Pliny merely states that the Essenes, a tribe dwelling on its banks, abandoned their stations on the approach of summer as unwholesome; just as other lakes in warm climates are pestilential at that season from marsh miasms. In the present day the air over it has nothing peculiarly pestilential. It has been repeatedly visited, and the supposed absence of animal life on and in its water is found to be fabulous. Heymann and Van Egmont observed swallows skimming along its surface; and a sparrow, which they had thrown into the lake after clipping its wings, easily regained the shore. Captain Lynch of the U. S. navy, saw ducks on its surface, and snipes, partridges, singing birds, and hares, on its shores. Some travellers have ascertained that the coral *porites elongata* lives in its waters; and Hasselquist and Maundrell long ago mentioned living shells as occurring in it. Dr Wilson observed shells of dead Clausilia and Pupa on its shores, which he supposes to have been carried into it by the Jordan, but may very well have lived there and been ejected after death on the beach. It has even been asserted that one small species of fish is peculiar to the Dead Sea. This designation of the lake seems to have arisen from the little agitation of its very dense waters by the winds, and the dull murmur they make on its shores. Its surface very speedily resumes its unruffled appearance on the ceasing of a gale, and is scarcely curled by a moderate breeze.

The lake occupies a portion of a very remarkable depression of the earth's surface, the Wady-el-Ghor Within the present century its surface has been found to be greatly below the level of the Mediterranean. The problem was attempted by Schubert and Russegger with the barometer; but it was more accurately determined by a series of levels taken by some French engineers, and by Lieut. Symonds of our Royal Engineers. The levels of the latter, carried from Jaffa to the Dead Sea, give the depression of the surface of the latter at 1312·2 feet. The French state it at 1446 feet below the Mediterranean, and 1407 below the Red Sea. The determination of Captain Lynch, U. S. navy, nearly agrees with that of Symonds. Three attempts have been made to survey it by boats; the first by Mr Costigan, an enterprising young Irish traveller in 1835; the next by Lieut. Molyneux, R.N., in 1847. Exposure to the sun proved fatal to both. In 1848, Captain Lynch was sent with iron boats and suitable apparatus by the American Government to survey the Dead Sea, and the result has been published. The lake is stated by Symonds to be $48\frac{1}{2}$ English miles in length, and $11\frac{1}{2}$ at its greatest breadth. Lynch makes its extreme length to be 42 miles from north to south, and rather less than 10 at its widest part. These measurements are much below its fancied dimensions. Even Mariti states its circumference at 180 miles. Its depth is very considerable. The greatest depth, according to the observations of Molyneux, is 225 fathoms; and even then it was uncertain whether the plummet struck the bottom. In the northern portion, between Ain-Jidi to the mouth of the Arnon, the mean depth, according to Lynch, for a distance of seven geographical miles, was 188 fathoms. The southern portion of the lake is shallow, and is divided from the deep part by a narrow peninsula of loose calcareous marl. To the south of this peninsula the depth is only about 13 feet. With regard to the bottom of the lake, it is in part rocky, but generally consists of a bluish mud or slime, containing cubic crystals of salt. Bitumen and asphalt are found on the east and west shores of the lake, with small masses of sulphur, especially at the end of the peninsula which Lynch has named Cape Costigan, a bluff 40 or 50 feet high, with an angular ridge 20 feet higher. The sulphur is occasionally in masses as large as a walnut, and the asphalt is manufactured into rosaries at Jerusalem. The north shores of the lake Lynch describes as an extensive flat of mud, with sandy plains beyond, and as the very type of desolation, with the blackened trunks and branches of trees strewed in every direction, partially encrusted with salt. The north-west shore consists of a bed of gravel sloping gently to the hills. The eastern shores are formed by the rugged sterile mountains of Moab, a branch of the Hauran range. The southern shore is low, flat, and marshy, of the most desolate aspect. The whole line of the west coast is formed of a range of rugged mountains like the eastern side. At the south-west extremity of the lake is the isolated ridge called the Mountain of Usdom, containing fossil salt. Here Lynch found a lofty detached pillar of salt, standing at the head of a deep narrow chasm. It is cylindrical in front, and pyramidal behind; it is of solid crystalline salt, capped by carbonate of lime. The upper part is 40 feet high, resting on an oval pedestal 40 or 50 feet above the water. It slightly diminishes in diameter as it ascends, and the top is of crumbling limestone. It is probably this pillar of salt which some travellers have mentioned as known to the Arabs under the name of "Lot's Wife."

Captain Lynch's survey was leisurely made; his boats were 22 days on the lake. He encountered a sudden squall on one occasion, when the sound of the waves against the boats is described as like that of sledge hammers rather than of waves of the sea; yet when the squall as suddenly ceased, within 20 minutes they were rowing along a placid sheet of smooth water scarcely rippling to the breeze. This comparative sluggishness of its waters is owing to their great density, which has no parallel except in the lately discovered Utah Lake of North America. Lynch once observed the sea extremely phosphorescent; which appearance we now believe to be produced by medusaria and other minute animals—a further proof that the waters of this celebrated lake are not hostile to life. The water, when examined in a glass, is clear and transparent; but Molyneux found it throughout at the period of his visit muddy like the waters of the Jordan; and he also speaks of its disagreeable smell. It has been chemically examined by Macquer, Lavoisier, Sage, Marcet, Klaproth, and last by Dr Salisbury of America. Its specific gravity as given by Lavoisier = 1·240; by Klaproth, 1·24; by Marcet, 1·211; by Salisbury, 1·1877. These differences may depend on the season of the year, and the proximity to the Jordan or the Arnon. Certain it is that its waters are far more buoyant than those of the Mediterranean. The ancients believed that men and animals, and even iron, floated entirely on its surface. Mr Stephens, a late American traveller, states that when he made the experiment, lying on his back without any motion of his hands, half his body remained above the surface, and he could easily have read in that position; although in the Mediterranean he could only float when using some slight motion of his hands.

The analysis of the water has been differently stated by eminent chemists; thus we have for its contents—

	Marcet.	Klaproth.
Muriate of lime	3·920	10·60
Muriate of magnesia	10·246	24·20
Muriate of soda	10·360	7·80
Sulphate of lime	0·054	0·00
	24·580	42·60
Water	75·420	57·40
	100·000	100·00

This striking difference probably depends on two causes:

Asphaltum ‖ Assafœtida.

the loss of some water by evaporation in the keeping of the specimen of water before analysis; and the difference in drying the salts before weighing them. That this last cause is very important we know; and Marcet found that when the saline ingredients were dried only at a temperature of 180° Fahr., they equalled 41 per cent. of the water examined. The analysis given by Dr Salisbury in the *Transactions of the American Scientific Association for* 1851, gives also minute quantities of potass, bromine, sulphur, silica, alumina, peroxide of iron with nitric, phosphoric, and carbonic acid, and organic matter, as ingredients in the waters of the Dead Sea; and no doubt he would also have found in them *iodine*, but his method of stating the proportions of each, while the bases of the other salts only are given, renders quantitative comparison unsatisfactory. He, however, states the ponderable contents of the water at 23·002 per cent. He further states that a gallon weighed 11·877 lb.; a cubic foot 71·175 lb., while that of distilled water only 62·32 lb.

The saltness of the lake is derived from extensive beds of salt that occur on its shores. At Usdom these beds extend five geographic miles in length, and form cliffs from 100 to 150 feet in thickness. The waters of the Jordan, though potable, contain exactly the same kind of saline substances as the lake; and as it has no outlet, the supply brought by the Jordan, the Arnon, and its other tributaries, must be removed by evaporation, leaving the salt behind; so that in process of time the lake may become a bed of fossil salt. The rugged mountains of Moab have all the character of erupted rocks; and the sulphur and bitumen, with the large disengagement of bubbles of gas from the deepest part of the lake, are probably indications of slumbering volcanic action. (T. S. T.)

ASPHALTUM, BITUMEN JUDAICUM, or JEW'S PITCH, is a light, solid bitumen, of a dusky colour on the outside, and a deep shining black within; of very little taste, and having scarcely any smell, unless heated, when it emits a strong pitchy odour. It is found in a soft or liquid state on the surface of the Dead Sea, and by age grows dry and hard. The same kind of bitumen is met with likewise in the earth in other places of the world—in China, America, and in some places of Europe, as the Carpathian Hills, France, Neufchatel, &c. See BITUMEN.

ASPHODELEÆ, a natural order of plants, containing, among others, the well-known vegetable, *asparagus*. This plant, and the root of the marsh-mallow, yield the chemical principle asparagine. See CHEMISTRY.

ASPHYXIA (ἀσφυξια), a temporary suspension of the motion of the heart and arteries, causing swooning or fainting.

ASPICUETA, or AZPILCUETA, MARTIN DE, commonly called the Doctor of Navarre, was descended of a noble family, and born on the 13th of December 1491, at Varasayn, near Pampeluna. He studied classics, natural and moral philosophy, and divinity, at Alcala in New Castile. After teaching with applause at Toulouse and Cahors, he was professor of canon law at Salamanca for 14 years, and afterwards at Coimbra for 20 years. Pope Pius V. made him assistant to Cardinal Francis Aciat, his vice-penitentiary; and Gregory XIII. never passed his door without calling for him, and stopped sometimes a whole hour to talk with him in the street. He was consulted as an oracle; and his name became so famous, that even in his lifetime the highest encomium on a learned man was to call him a *Navarrus*. He died on the 21st June 1586, having by temperance prolonged his life to the age of 94. He wrote a number of treatises on morality, law, &c. These were published in 3 vols. folio, Rome, 1589; and in 6 vols. 4to, Venice, 1602.

ASS. See MAMMALIA.

ASSAFŒTIDA, a fœtid gum resin, obtained by exudation from the roots of at least two species of umbelliferous plants, *Ferula Assafœtida* and *F. Persica*. The best comes from Persia and Herat. Another locality has lately been assigned on the northern slope of the Himalayas in Sŷghan. That produced in Northern Persia from *F. Persica*, is inferior in quality to that of Eastern Persia. See BOTANY.

Assam.

ASSAM, a province of Eastern India, situate in the north-east of the Bengal territory, between the 25th and 29th degrees of north latitude, and the 90th and 97th degrees of east longitude. Its boundaries are Bhotan on the north and north-west; Thibet on the north-east; Burmah on the south-east; Cachar, Jyntea, and the tract inhabited by the Cossya tribes on the south; and the district of Goalpara on the west. Assam is an immense valley, surrounded on all sides, except upon the west, by mountains of considerable elevation, and interspersed with numerous eminences in the interior, rising abruptly from the general level. The whole superficies is calculated at 21,805 sq. miles, a large portion of which is occupied by woods and rivers. Probably the rivers intersecting Assam are more numerous than those of any other country of equal extent, a consequence resulting from its being environed by hills. The valley is divided throughout by the Brahmapootra into two nearly equal parts; and many islands, some of them very large, are formed by the confluence and mutual intersection of numerous rivers, which contribute alike to fertilize the ground and to facilitate the intercourse of the inhabitants. Of these rivers not less than sixty-one are known and distinguished by particular names, of which thirty-four flow from the northern, twenty-four from the southern mountains, and the remainder from sources beyond the confines of Assam. The streams of the south are not rapid, and have no considerable current until May or June.

Boundaries, rivers, and natural features.

The Brahmapootra, one of the largest rivers in the world, derives its source from a well or circular basin at the eastern extremity of the Brahmakund valley; it enters Assam not by a deep chasm, but by a series of cascades caused by the accumulation of blocks of stone which have been propelled forward by the torrent, and thus create a succession of rapids. Its earliest feeders after crossing the frontier are the Kundil and the Digaroo, flowing from the Mishmi Hills on the north, and the Tenga Pence and Noh Dihing which take their rise on the Singpho Hills to the south-east. Shortly afterwards it receives the Dibong, flowing from the north-east; but its principal confluent is the Dihong, which deriving its origin under the name of the Sanpoo, from a spot in the vicinity of the source of the Sutlej, flows in a direction precisely opposite to that river, and traversing the table-land of Thibet at the back of the great Himalaya range falls into the Brahmapootra in Lat. 27. 48., Long. 95. 26., after a course of nearly 1000 miles. Doubts were long entertained whether the Dihong could be justly regarded as the continuation of the Sanpoo; these, however, have been gradually removed by the additional testimony of more recent notices; and as it is ascertained moreover that the last-named river does not flow into the Irawaddy, it appears impossible to account for its course to the sea, except by presuming it to discharge its waters into the Brahmapootra through the channel of the Dihong. Below the confluence the united stream flows in a south-westerly direction, forming the boundary between the districts of Luckimpore and Durrung, situate on its northern bank, and those of Sudiya, Seebpoor, and Nowgong on the south; and finally bisecting Camroop, the lowest of the six districts into which Assam is distributed, it crosses over the frontier of the province and passes into Bengal. In its course it receives on the left side the Booree Dehing, a river having its rise at the south-eastern angle of the province; and lower down on the opposite side it parts with a considerable offset termed the Booree Lohit, which, however, reunites with the Brahmapootra 60 miles below the point of divergence, bearing with it the additional waters of the Sobu Sheree flowing from Thibet. A second offset under the name of the Kul-

Assam.

lung River rejoins the parent stream a short distance above the town of Gowhatty. The remaining rivers are too numerous to be particularized. Among the islands formed by the intersection and confluence of the rivers is Majuli, or the Great Island, as it is called by pre-eminence. This island extends 55 miles in length by about 10 in breadth, and is formed by the river Brahmapootra on the south-east, and the Booree Lohit on the north-west. A Persian writer, Mahommed Cazim, in describing Assam at the latter end of the seventeenth century, makes some observations on its general appearance, which, as he bore no favour to the inhabitants, may probably merit the greater confidence. He thus speaks of Majuli—"an island well inhabited, and in an excellent state of agriculture; it contains a spacious, clear, and pleasant country. The cultivated part is bounded by a thick forest which harbours elephants, and where these animals may be caught as well as in four or five other forests in Assam. If there be occasion for them, five or six hundred elephants may be procured in a year." Describing the country south of the Brahmapootra, the same author observes, "across the river on the side of Ghergong is a wide, agreeable, level country that delights the heart of the beholder. The whole face of it is marked with population and tillage; and it presents on every side charming prospects of ploughed fields, harvests, gardens, and groves. From the village of Salagerah to the city of Ghergong, a space of about 50 coss (100 miles), is filled with such an uninterrupted range of gardens, plentifully stocked with fruit trees, that it appears as one garden. Within them are the houses of peasants, and a beautiful assemblage of coloured and fragrant herbs, and of garden and wild flowers blowing together. As the country is overflowed in the rainy season, a high and broad causeway has been raised for the convenience of travellers from Salagerah to Ghergong, which is the only uncultivated ground that is to be seen. Each side of this road is planted with shady bamboos, the tops of which meet and are entwined. Among the fruits which this country produces are mangoes, plantains, jacks, oranges, citrons, limes, and punialeh, a species of ambleh, which has such an excellent flavour that every person who tastes it prefers it to the plum. There are also cocoanut trees, pepper-vines, areca trees, and the sadij (an aromatic leaf), in great plenty. Sugar cane excels in softness and sweetness, and is of three colours, black, red, and white; there is ginger free from fibres and betel vines. The strength of vegetation and fertility of the soil is such, that whatever seed is sown, or slips planted, they always thrive. The environs of Ghergong furnish small apricots, yams, and pomegranates; but as these are wild, and not assisted by cultivation and engrafting, they are very indifferent. The principal crop of this country consists in rice and mash. Ades, a kind of pea, is very scarce, and wheat and barley are never sown." And in respect to the other great division of the province he remarks, "The country which is on the northern side of the Brahmapootra is in the highest state of cultivation, and produces plenty of pepper and areca nuts. It even surpasses the southern portion in population and tillage; but as the latter contains a greater tract of wild forests, and places difficult of access, the rulers of Assam have chosen to reside in it for the convenience of control, and have erected in it the capital of the kingdom. The breadth of the Northern Division from the bank of the river to the foot of the mountains, which is a cold climate and contains snow, is various, but is nowhere less than 30 miles nor more than 90. The inhabitants of those mountains are strong, have a robust and respectable appearance, and are of a middling size. Their complexions, like those of the natives of all cold climates, are red and white; and they have also trees and fruits peculiar to frigid regions." Various agricultural products appear to have been introduced since the time of Mahommed Cazim. Wheat and barley are now raised, though only to a small extent; but cotton, tobacco, and the poppy are extensively grown. The indigenous trees producing lac, and those yielding the gum known as caoutchouc, are of great importance. But perhaps the most valuable of the vegetable products of Assam is the tea plant. This was first discovered in 1823, while the country was part of the Burmese dominions, by Mr Robert Bruce, who had proceeded thither on a mercantile speculation. The war with the British breaking out shortly after, and a brother of the first discoverer happening to be appointed to the command of a division of gun boats employed in some part of the operations, he followed up the pursuit of the subject and obtained several hundred plants and a considerable quantity of seed. Some specimens were ultimately forwarded to the superintendent of the Botanic Garden at Calcutta. In 1832 Captain Jenkins was deputed by the Governor-general of India, Lord William Bentinck, to report upon the resources of the country, when the tea plant was brought to his especial notice by Mr Bruce; and in 1834 a minute was recorded by the Governor-general on the subject, to which it is said his attention had been called in 1827 before his departure from England. In accordance with the views of that minute, a committee was appointed to prosecute inquiries, and to promote the cultivation of the plant. Communications were opened with China with a view to obtaining plants and seeds from thence, and a deputation composed of gentlemen well versed in botanical studies was despatched into Assam. Some seeds were obtained from China; but this probably was of small importance, as it was clearly ascertained by the members of the Assam deputation, that both the black and the green tea plants were indigenous there, and might be multiplied to any extent; but another result of the Chinese mission, that of procuring persons skilled in the cultivation and manufacture of black tea, was of more material benefit. Subsequently, under Lord Auckland, a further supply of Chinese cultivators and manufacturers was obtained, these being acquainted with the processes necessary for the production of green tea, as the former were with those requisite for black. In 1838 the first twelve chests of tea from Assam were received in England. They had been injured in some degree on the passage, but on samples being submitted to brokers and others of long experience and tried judgment, the reports were highly favourable. It was never, however, the intention of government to carry on the trade: from the first it was proposed to resign it to private adventure, as soon as the experimental course could be considered fairly completed. Mercantile associations for the culture and manufacture of tea in Assam began to be formed as early as 1839, and in 1849 the government disposed of their establishments, relinquishing the pursuit to the ordinary operation of commercial enterprise. In 1851 the crop of the Assam Tea Company was estimated to produce 280,000 lb., and the general aspect of the affairs of that company is described in their latest report as satisfactory and promising.

Vegetable products.

Cultivation of tea.

The climate of Assam is said to be more temperate than that of Bengal, and subject to less variation. The warm weather is moderate, and the nights cool and refreshing. The mean temperature of the four hottest months does not exceed 80°; that of the winter season amounts to 57°, and the mean annual temperature may be stated at 67°. The rains are of unusual duration, commencing in March and continuing till the middle of October. Earthquakes are frequent. No less than twelve are stated to have occurred in the twelve months between May 1834 and May 1835: in 1845 a shock was experienced at Nowgong, whereby considerable damage was sustained.

Geology.

A meagre sketch is all that is possessed of the geology of Assam. The mountains on the opposite sides of the valley are characterized by distinct systems, those on the north being composed of primitive formations, while those on the south partake largely of sandstone, shell-limestone, and coal. Some

Assam.

Minerals.

valuable minerals, however, are met with: gold-dust is found in all the rivers flowing from the northern mountains, but it differs in purity and colour, and also in malleability. That which is obtained in the Dekrungh is particularly celebrated, and is distinguished by a higher colour than that found in the Brahmaputra, though it is more abundant in the bed of the latter river. The greatest quantities of gold are found nearest the mountains, which probably indicates that it is carried down from them by the torrents; but it is never sought in the southern rivers. Beds of iron ore exist in various places, and tracings of former workings to a considerable extent remain; but the native article being undersold by iron imported from England, as well as from adjacent provinces, is by this competition driven out of the market. In noticing the mineral productions, coal must not be overlooked. It has been discovered in beds of considerable magnitude, from the banks of the Noh Dihing in the south-eastern extremity of the province, to the vicinity of the Kossilei River, within 60 miles of Gowhatty; and from the circumstance of its existence at these two extremities, as well as in several intermediate localities, there appear grounds for the inference that the coal formations of Assam are co-extensive with the whole length of the valley. In 1851 specimens of this mineral, derived from the coal-bed of Jaipur, on the Booree Dehing, were forwarded by the Government of India for analysis to Professor Oldham, the superintendent of the geological survey. The professor's report, though not given sufficiently in detail, owing to the condition in which the specimens reached their destination, was still so far encouraging as to induce the belief that the labour of further search would be amply remunerated. Neither copper nor silver are found in Assam. Rock-salt is dug out of the earth, and brine springs are not uncommon in some localities, from the produce of which salt is made; but the manufacture is costly, and the salt is fully as expensive as that imported.

Animals.

The zoology of Assam presents little that is remarkable. Wild elephants abound and commit many depredations, entering villages in large herds, and consuming everything suitable to their tastes. Many are caught by means of female elephants previously tamed, and trained to decoy males into the snares prepared for subjecting them to captivity. A considerable number are tamed and exported from Assam every year, but the speculation appears to be somewhat precarious, as it is said about twice the number exported are annually lost in the course of training. Many are killed every year in the forests for the sake of the ivory which they furnish; and the supply must be very great which can afford so many for export and destruction without any perceptible diminution in their number. The rhinoceros is found in the denser parts of the forests, and generally in swampy places. This animal is hunted and killed for its skin and its horn. The skin affords the material for the best shields. The horn is sacred in the eyes of the natives. Contrary to the usual belief, it is stated that if caught young, the rhinoceros is easily tamed, and becomes strongly attached to his keeper. Tigers abound, and though many are annually destroyed for the sake of the government reward, their numbers seem scarcely at all to diminish. Their destruction is sometimes effected by poisoned arrows discharged from an instrument somewhat resembling a cross bow, in which the arrow is previously fixed, and a string connected with the trigger carried across the path in front of the arrow, and fastened to a peg. The animal thus struck is commonly found dead at the distance of a few yards from the engine prepared for his destruction. Leopards and bears are numerous; and the *Arctonix Collaris* of Cuvier, a small animal somewhat resembling a bear, but having the snout, eyes, and tail of a hog, is found. Among the most formidable animals known is the wild buffalo, which is of great size, strength, and fierceness. Many deaths being caused by this animal, a reward is given for its destruction. The fox and the jackal exist, and the wild hog is very abundant. Goats, deer of various kinds, hares, and two or three species of antelope are found, as are monkeys in great variety. The porcupine, the squirrel, the civet cat, the ichneumon, and the otter are common. The birds are too various to admit of enumeration—wild game is plentiful; pheasants, partridges, snipes, and water fowl of many descriptions furnish attraction for the sportsman. Vultures and some other birds of prey are met with. Crocodiles swarm in all parts of the Brahmaputra. Tortoises are numerous, and constitute a staple article of food sold in the bazaars. Porpesses are common, their favourite resort being the entrance of some tributary stream into the great river. There they are hunted and speared by the natives. Serpents of many kinds exist. Leeches abound; and a land leech is very common in the hills, especially during the rains, when it is found clinging to every bush and blade of grass. It is believed that it might be applied in the exercise of the curative art, as harmlessly as the ordinary medicinal leech, and with similar results. The Brahmaputra abounds with very fine fish in great variety, including the mullet.

Assam.

History and manners of the inhabitants.

The population of Assam is returned at 780,935. The Assamese are descendants of a race called Ahoms, who, about the thirteenth century, emigrated from some more eastern region and possessed themselves of the country; but having no females of their own race, took wives from the aborigines, a circumstance favourable to their stability. Of the religion of the conquerors it seems impossible to speak except in negative terms. It is said to have exhibited no trace of Bhudhism. Its followers were not Hindus, for they ate beef; nor Mahometans, for they were consumers of pork. Other descriptions of animal food, almost universally considered repulsive, entered into their gastronomic repertory, and in this respect they seem to have resembled the Chinese. The Assamese have been described as a degenerate, weakly race; more so, indeed, than the people of Bengal. This, however, is questioned by late observers, who, while admitting the Assamese to be physically inferior to the people of the north-west provinces, regard them as greatly superior to those of Bengal. In complexion they are represented to be somewhat lighter than the Bengalese. Their faces are flat; they have high cheek-bones, and in general physiognomy bear a resemblance to the Chinese. Their hair is black, coarse, and lank. The beard is scanty, and the small quantity bestowed by nature is usually plucked out. The personal characteristics of the women are decidedly superior to those of the other sex. They are fair to a degree not usually met with in India, and many of them, it is said, would in any part of the world be considered beautiful. In most parts of the country they do not affect the personal concealment common in the East, but appear in public as in Europe. The state of morals in both sexes is low. Among the men falsehood and knavery are predominant. They are lazy and utterly careless as to making provision for the future. If compelled to labour, they abandon their work after a day or two, and resort to the more pleasant occupations of drinking arrack and chewing opium. The female part of the population estimate lightly that virtue which is the peculiar ornament of their sex. It is considered a disgrace for a girl to remain unmarried after the attainment of a marriageable age; but, as among the humbler classes this is often unavoidable, the fact of her becoming a mother before she is a wife occasions no scandal, and a parent will bargain for her daughter's honour with as much coolness as if for the sale or hire of a domestic animal. The health of the women is said to be injuriously acted upon by this state of manners and morals. Those who escape the stigma attached to protracted spinsterhood incur the cares and dangers of maternity before the constitution has acquired sufficient strength to sustain them without injury; while those who remain unmarried till a later period of life do not necessarily escape this source of debility, while they are exposed also to the enervating consequences of a career of illicit indulgence. Children are not numerous, and of those born the proportion who die before reaching the second stage of life is large. The darker shades of Assamese life are, however, relieved by a few gleams of light. The respect paid to old age is great. The affection of parents for their children also appears strong, and the bonds of family connection generally are maintained and strengthened by the exercise of kindness. Beyond their own caste, how-

ever, little of good-feeling seems to exist among the people. The Assamese have always been a people of warlike habits; this fact being vouched not only by their original conquest, but by the extension also of the conquered territory. In 1638, during the reign of the Emperor Shah Jehan, the Assamese descended the Brahmaputra and pillaged the country round the city of Dacca; they were expelled by the governor of Bengal, who retaliated upon the plunderers by ravaging Assam. During the civil wars between the sons of Shah Jehan, the king of Assam renewed his predatory incursions into Bengal: upon the termination of the contest, Aurungzebe determined to avenge these repeated insults, and despatched a considerable force for the regular invasion of the Assamese territory. His general, Meer Jumla, defeated the Rajah, who fled to the mountains, and most of the chiefs made their submission to the conqueror. But the rains set in with unusual violence, and Meer Jumla's army was almost annihilated by famine and sickness. Thus terminated the last expedition against Assam by the Mahometans, whose fortunes in this country were never prosperous. A writer of the Mahometan faith says, "Whenever an invading army has entered their territories, the Assamese have sheltered themselves in strong posts, and have distressed the enemy by stratagems, surprises, and alarms, and by cutting off their provisions. If these means failed they have declined a battle in the field, but have carried the peasants into the mountains, burned the grain, and left the country desert. But when the rainy season has set in upon the advancing enemy, they have watched their opportunity to make excursions and vent their rage; the famished invaders have either become their prisoners or been put to death. In this manner powerful and numerous armies have been sunk in that whirlpool of destruction, and not a soul has escaped." The same writer states that the country was spacious, populous, and hard to be penetrated; that it abounded in dangers; that the paths and roads were beset with difficulties; and that the obstacles to conquest were more than could be expressed. The inhabitants, he says, were enterprising, well armed, and always prepared for battle. Moreover they had lofty forts numerously garrisoned and plentifully provided with warlike stores; and the approach to them was opposed by thick and dangerous jungles, and broad and boisterous rivers. The difficulties in the way of successful invasion are of course not extenuated, as it was the object of the writer to exalt the prowess and perseverance of the faithful. He accounts for their temporary success by recording that, "the Mussulman hordes experienced the comfort of fighting for their religion, and the blessings of it reverted to the sovereignty of his just and pious majesty." The short-lived triumph of the Mussulmans might, however, have warranted a less ambitious tone. About the middle of the seventeenth century the chief became a convert to Hinduism. By what mode the conversion was effected does not clearly appear, but whatever were the means employed it seems that the decline of the country commenced about the same period. Internal dissensions, invasion, and disturbances of every kind convulsed the province, and neither prince nor people enjoyed security. Late in the eighteenth century some interference took place on the part of the British government, then conducted by Lord Cornwallis; but the successor of that nobleman, Sir John Shore, adopting the non-intervention policy, withdrew the British force, and abandoned the country to its fate. Its condition encouraged the Burmese, an aggressive people, to depose the Rajah and to make Assam a dependency of Ava. The extension of their encroachments on a portion of the territory of the East India Company compelled the British Government to take decisive steps for its own protection. Hence arose the series of hostilities with Ava, known in Indian history as the first Burmese war, on the termination of which by treaty in February 1826, Assam remained a British possession. In 1833 that portion of the province denominated Upper Assam, was formed into an independent native state, and conferred upon Poorunder Sing, the ex-Rajah of the country; but the administration of this chief proved unsatisfactory, and in 1838 his principality was reunited with the British dominions. (E. T.)

ASSARIUM, in *Antiquity*, denotes a small copper coin, being a part or diminutive of the *as*. The word ἀσσάριον is used by Suidas indifferently with ὀβολός and νόμισμα, to denote a small piece of money; but according to Polybius (ii. 15), the assarium was equal to half the ὀβολός, or $3\frac{1}{4}$ farthings. We find mention of the assarium in the gospel of St Matthew, chap. x. ver. 29.

ASSASSIN, a person who kills another with the advantage either of an inequality in the weapons, or by means of the situation of the place, or by attacking him unawares. The word *assassin* is said by some to have been introduced from the Levant, where it took its rise from a certain prince of the family of the *Arsacidæ*, popularly called *Assassins*, living in a castle between Antioch and Damascus, and bringing up a number of young men, ready to pay a blind obedience to his commands; whom he employed in murdering the princes with whom he was at enmity. This people probably owed their origin to the Carmatians, a famous heretical sect among the Mahometans, who settled in Persia about the year 1090; whence, in process of time, they sent a colony into Syria, where they became possessed of a considerable tract of land among the mountains of Lebanon, extending itself from the neighbourhood of Antioch to Damascus. According to Colonel Chesney, the Assassins, or Ismaïli, have their chief seat still at Kalat-el-Masryad in Persia; and they have several strongholds in the mountains of Tripoli. Their name is most probably derived from the intoxicating plant *Cannabis indica*, which they use, and which is called *Hacchisshin* in Persic; "and has no connection with the *Old Man of the Mountain*." The first chief and legislator of this remarkable tribe appears to have been Hassan Ben Sabah, a subtle impostor, who by his artifices made fanatical and implicit slaves of his subjects. Their religion was compounded of that of the Magi, the Jews, the Christians, and the Mahometans; but the capital article of their creed was to believe that the Holy Ghost resided in their chief; that his orders proceeded from God himself, and were real declarations of his divine pleasure. To this monarch the orientals gave the name of *Sheikh-el-Jebelz;* but he is better known in Europe by the name of the *Old Man of the Mountain.* This chief, from his residence on Mount Lebanon, like a vindictive deity, with the thunderbolt in his hand, sent inevitable death to all quarters of the world; so that from one end of the earth to the other, caliphs, emperors, sultans, kings, princes, Christians, Mahometans, and Jews, every nation and people, execrated and dreaded his sanguinary power, from the strokes of which there was no security. At the least suggestion or whisper that he had threatened the death of any potentate, all immediately doubled their guards, and took every other precaution in their power. It is known that Philip Augustus, king of France, on a premature advice that the sheikh intended to have him assassinated, instituted a new body-guard of men distinguished for their activity and courage, called *sergens d'armes*, with brass clubs, and bows and arrows; and he himself never appeared without a club, fortified either with iron or gold. Most sovereigns paid secretly a pension to the sheikh, however scandalous and derogatory it might be to the lustre of majesty, for the safety of their persons. The knights-templars alone dared to defy his secret machinations and open force. This people once had, or at least they feigned to have, an intention of embracing the Christian religion. They reigned a long time in Persia and on Mount Lebanon. Holagoo or Hu-

Assaying.

laku, a leader of the Mogul Tartars, in the year 655 of the Hegira, or 1254 of the Christian era, entered their country and dispossessed them of several places; but it was not till some years after that they were totally extirpated. This achievement was owing to the conduct and intrepidity of the Egyptian forces sent against them by the Sultan Bibars.

A *History of the Assassins*, in the German language, by Mr Von Hammer, was published at Stuttgard in 1818. It contains some new and striking views of the origin, proceedings, and doctrines of the sect. He represents them as forming a military and religious order, subject to the control and direction of a grand master, like the templars, to whom the title of Old Man of the Mountain was applied. This learned and curious work has been translated into English by Mr Wood.

ASSAULT, in *English Law*, is an offer or attempt to hurt the person of another; as, if one lift up his cane or his fist in a threatening manner at another, or strike at him, but miss him, this is an assault; the actual touching of the person not being necessary to make the offence. Finch describes it to be "an unlawful setting upon one's person." No words whatsoever, be they ever so provoking, can amount to an assault. There are, however, opinions to the contrary.

ASSAY, Essay, or Say, in *Metallurgy*, the proof or trial of the goodness, purity, value, &c., of metals and metalline substances. In ancient statutes this is called *touch*, and those who had the care of it *keepers of the touch*.

ASSAYING, taken in its general acceptation, is a chemical process by which any ore, or other metallic compound, is analysed, and its constituent parts determined. But the term more particularly denotes the peculiar art by which gold and silver are examined, and their qualities ascertained, in relation to their state of purity. By the former the whole contents of the substance under examination are separated and collected; by the latter it is only necessary in practice to find, by the destruction or separation of the alloys, the amount of pure metal contained in the specimen operated on, so that a value may be given, by computation, to the whole mass. To this specific branch we purpose to confine ourselves in the following observations.

Importance of this art.

The art of assaying the precious metals must be esteemed of considerable importance in many points of view; but more especially to commercial nations trading extensively in these commodities. For although the ultimate destination of these metals be their conversion into coin, plate, or other articles of use and ornament, still there are vast treasures of bullion consigned to the stores of different countries merely as commodities, as convenient representatives of value, or in security for nominal wealth, the marketable value of which is determined solely by the skill and accuracy of the assayer. Every one having experience of such matters knows that, unlike other things of a mercantile nature, bullion cannot be valued by its bulk, weight, or any simple external characteristic, but by ascertaining in some way the amount of fine metal contained in a given quantity. And implicit confidence being placed in the honesty, accuracy, and fidelity of the assayer, who, by examining a small portion only, gives a certificate of its quality upon which the whole is estimated, merchants are enabled to buy and sell bullion without risk of loss, and with the most perfect assurance of the value being maintained. By means of the art of assaying, as applicable to small as to large things, we also possess a certain safeguard against fraud in the manufacture of plate and other articles of personal or domestic use, which must be regarded as of some importance in a country rich and affluent like Great Britain, where gold and silver have become so common amongst the middle classes as scarcely to be esteemed luxuries. We could only wish that the laws which prevail in reference to plate were more generally extended in their application to the manufacture of jewellery, and other personal ornaments; for in these things the public have no guarantee against fraud and knavery beyond the character or assurance of the dealer.

If the art of assaying be deemed valuable and important as regards bullion and plate, securing a certain and reliable test of value, as well as a sufficient check upon fraudulent designs, we cannot surely question its even greater importance in reference to the metallic currency of a country, the standard accuracy of which affects materially the interests of all, and so far tends to promote the welfare of mankind. Whatever this standard be, it is obvious the value of all property in exchange must be regulated and determined by it, whether in land, houses, commodities, or the wages of labour; and if we had no reliance on the integrity of our coin, as a measure of value, we could enjoy no security in our property. In all countries, therefore, claiming a character for honesty, the integrity of the standard should be a fundamental principle. Any, the slightest, deviation from it, will instantly be discovered, followed by a loss of credit, and violent fluctuations in the exchange, which of all things are most injurious to trading communities. For the exchange between one country and another is not determined by coin merely as a circulating medium, but, in reality, by the exact amount of fine metal contained in the coin; and, therefore, it is necessary to know that the proportion is maintained called *the standard*, which, in our gold currency, consists of eleven-twelfths of pure metal and one-twelfth of alloy. This fact can only be ascertained by the process of assay. But when nations acquire a character for honesty and integrity, the currency will freely circulate all over the world without suspicion, at its reputed value, and the currency of one be easily converted into the currency of another. But we should fail to secure this great advantage, this implicit confidence, without the assayer's skill and check, by which the due proportions of metal are guaranteed, and any depreciation detected.

We need now no longer apprehend any of those capricious and dishonourable changes in the currency, not unknown to our history before the reign of Elizabeth, which enriched the monarch at the expense of his subjects, created sudden and violent changes in the value of property, and often spread dismay and poverty amongst all classes, without any clear knowledge of the cause. That patriotic and sagacious queen, of whom England is justly proud, among other great and durable merits, is honourably distinguished by the restoration of our currency to purity, and by fixing our present standard of value, from which, happily, no deviation can be notified in succeeding ages. In this respect science and knowledge, if not always the handmaids of integrity, are the best guarantees against fraud and evil designs; and we can scarcely believe it possible, in these times, to suffer from a dishonourable depreciation of the currency, while any vague apprehension of error is instantly dissipated by the numerous checks, public and private, on the purity of our coin. Amongst these we may briefly instance the ancient ceremony called the *Trial of the Pyx*, which, in the most public manner, secures an impartial examination of the coinage, and a verdict, as public, of its legal or standard purity. In no other country have we been able to discover an institution analogous to this, which, after all intermediate tests have been tried in the process of manufacture, affords an ultimate and judicial appeal for the public satisfaction. And it may be added, to the credit of the officers of the Mint, that, whatever may happen in future times, amid the sudden and hasty revolutions in public affairs, during the past we are unable to adduce any instance of this ordeal being passed without honour and integrity; and instead of the allowance or remedy by law for errors, unavoidable in manufacture, being taken advantage of, as a protec-

Trial of the Pyx

tion to carelessness, we may pronounce that the coinage has always been proved to be as nigh to the legal standard as is possible, the deviation being on the average scarcely worth notification.

The *Trial of the Pyx* takes place once in about every three years, but no specified period is fixed by law. It is so denominated from the pyx, or chest, in which the specimen coins are deposited in the Mint for future examination; these specimen coins being supposed a fair representation of the whole money coined within a certain period. Out of each bag of coin, whether gold or silver, two pieces are taken, one for the trial by assay within the Mint, the other for the general pyx; and these are carefully sealed up in paper by three officers, and deposited in the chest. It should be remarked, that previously to the issue of coin to the public, a minor pyx takes place within the Mint, intended for the examination of the coined money by appointed officers, as regards both weight and fineness, and no coin is permitted to be delivered before it has passed this necessary ordeal.

It having been notified to the government that a trial of the pyx is called for, the Lord Chancellor issues his warrant to summon a jury of goldsmiths, who, on the appointed day, proceed to the Exchequer Office, Whitehall, and there, in presence of several privy-councillors, and the officers of the Mint, receive the solemn charge of the Lord Chancellor, who directs them in their important functions, and requests them to deliver to him a verdict of their finding. A piece of gold and silver, cut from the *trial-plates* deposited in the Exchequer, supposed to be of the exact legal standard, are delivered to the foreman of the jury, who is required to declare to what degree the coin under examination deviates from them. This being done, the jury proceed to Goldsmith's Hall, London, where assaying apparatus, and all other necessary appliances, are in daily use for the trial of gold and silver plate; and sealed packets of the specimen coins being delivered to them by the officers of the Mint, they are first tried by weight, and then a certain number are taken from the whole and melted into a bar, from which the assay trials are subsequently taken.

The verdict of the jury, founded on the results of these proceedings, proving favourable, the Master of the Mint and subordinate officers are released from all further responsibility, while the country receives, by the publicity of the verdict, an attestation of the standard purity of the coinage.

In times of comparative ignorance, the art of assaying was esteemed a mystery, and, like some other crafts, the practice of it was retained in few hands. There were supposed secrets in the conduct of the processes which none but the initiated were permitted to know; but now it is admitted that those secrets are nothing but the knowledge acquired by long experience, amounting in reality to certain allowances or adjustments in the results of the operations. The uncertain tests and appliances employed in ancient times, which afforded only a wide approximation to truth, and exposed the public to extortion and fraud, have in more scientific times been superseded by chemical processes as accurate as they are delicate and beautiful. The exquisite and varied laws of nature, in connection with metals and their transformations, are made instrumental to the use and knowledge of mankind; and science, so called, enables man to nicely balance and estimate the vast treasures found in the bowels of the earth, and constitute them measures of value more unchanging than any other product of nature. As science has progressed, so has the art of assaying improved, while in modern times new fields have been opened up for its use and application. Along with increased accuracy, it has become more varied and extensive in its practice. The amount of the precious metals have not only increased immeasurably, thereby magnifying the importance of the art, but in recent times changes in the mode of refining or separating these metals have created a new branch of business little practised in former ages. The application of sulphuric acid to separate gold from silver, and silver from gold, by which the operation is effected with great economy, and nearly all the contents recovered at comparatively little cost, has led to an extensive business in *parting* assays, which did not formerly exist. In this manner the holder of bullion, of a mixed character, has a higher value put upon his metal by reason of the gold or silver contained in it; and in the market he is able to realize the whole value by assay, less the deduction made to cover the charge of refining. The *parting* assay is different from the simple assay in this, that it declares upon the certificate of a gold assay the amount of silver combined with it, and of a silver assay the number of grains of fine gold contained in each pound.

The bullion to be valued having been melted into ingots or bars, small pieces are cut from each and folded separately in slips of paper with a corresponding mark or number of the bar, so as to preserve the identification of the assay reports with the bars. On these slips of paper the assayer writes his report, which declares the quality of the gold and silver, and this is the certificate upon which the bullion is bought and sold in the market. The Bank of England, however, and the Mint, in order to guard against any surreptitious change, or fraud, require the assays upon which they receive bullion to be cut off in presence of appointed officers. The assayer reports gold by *carats,* and silver by pennyweights. In the one case the Troy pound is divided into 24 parts or carats, and British standard being $\frac{11}{12}$ths fine gold and $\frac{1}{12}$th alloy, the carat will thus represent 10 dwts. Troy, the standard being therefore 22 carats fine and 2 carats alloy. In the other the Troy pound is divided into 240 dwts., and the standard of silver being 222 dwts. fine and 18 dwts. of alloy, the pennyweight will represent the $\frac{1}{240}$th of the pound.

Assay weights and reports.

Carats are subdivided into four carat grains, = 60 Troy grains each, and these are again further subdivided into eighths of a carat grain, = $7\frac{1}{2}$ grains Troy. The lowest trade report of gold is one-eighth of a carat grain, and of silver, half a pennyweight. In reporting gold, the practice in general use is to take 2 carats as the representative of fine gold for bullion *better* than standard, and 24 carats for bullion *worse* than standard. Thus a bar reported *better* 1. $3\frac{3}{4}$, or one carat, three carat grains, and three-quarters of a grain, is within one-quarter of a carat grain of purity, or 15 grains Troy. But if a bar were found to contain only one-half of fine gold, the report would not be one carat worse, but *worse* 12 carats, or $\frac{12}{24}$ths. We may observe, however, that this complex mode of enumeration, so great a mystery to the uninitiated, will probably in a few years be entirely superseded by the decimal system of notation in general use on the continent. Already it is partially adopted by assayers in England, who are now required to append the decimal report, to the ordinary one, on the certificate. Instead of carats and pennyweights, the numeral 1000 will represent fine gold and silver, and any deviation in purity from this will be expressed by a decimal instead of a vulgar fraction.

It has been already remarked that the lowest denomination of the trade report is $\frac{1}{8}$th of a carat grain, or $7\frac{1}{2}$ grains Troy, as respects gold, and half a pennyweight, or 12 grains, as respects silver; but practically an assayer can arrive at a much nearer approximation to the truth. As in the Royal Mint, in making the combination for standard coin, he can report to a single grain, or $\frac{1}{5760}$th, in each case; but in buying and selling bullion some protection to the purchaser is deemed necessary as an indemnity against errors and irre-

Assaying.

gular mixture of the alloy, and hence arises the above latitude in the assay report. It is probable, however, that the general use of decimal notation will eventually cause a more accurate report, and deprive the bullion dealer of a share of that advantage which obviously is greater than is necessary.

An ordinary assay report of gold and silver expresses the variation from the standard, and not the fine metal contained in it; and it is, therefore, marked as either better or worse than standard. The standard of gold being 22 carats fine and 2 alloy, or $\frac{11}{12}$ths fine, an ingot of gold found to contain only 21 carats pure gold would be reported *worse* 1 carat; if it contained $23\frac{1}{2}$ carats, it would then be reported *better* 1 carat, 3 grains, and half a grain. The standard of silver being 11 oz. 2 dwts. fine, and 18 dwts. alloy, an ingot of silver found to contain only 11 oz. of fine would be reported *worse* 2 dwts., but if it contained 11 oz. $4\frac{1}{2}$, the report would then be *better* $2\frac{1}{2}$ dwts.

In buying or selling, the *betterness* or *worseness* of the bar is added or deducted from the gross weight; and the value is computed on this, the standard weight, at the market price of the day.

When the assay required is a *parting* assay, or an assay of gold containing silver, a report is given of the weight of fine silver in the pound; and when the silver exceeds 15 dwts. per pound, all above that is usually added to the value of the gold, that being an allowance made by general agreement for the cost of separation or refining. So likewise with an assay of silver holding gold. The report declares the number of grains of fine gold in the pound, and all above 3 or 4 grains is added to the computed value of the silver.

In these delicate operations we need scarcely impress upon the reader how important an instrument an accurate balance must be in securing a certain and uniform result. The specimen taken by an assayer is no more than 12 or 15 grains of the mass, and if 12 grains, each grain would represent an ounce, or $\frac{1}{480}$th. In the Royal Mint, the fine balances in use are sensible to the $\frac{1}{1000}$th of a grain.

The principle of assaying gold and silver is very simple theoretically, but in practice great experience is necessary to insure accuracy; and there is no branch of business which demands more personal and undivided attention. The result is liable to the influence of so many contingencies, that no assayer who regards his reputation will delegate the principal processes to one not equally skilled with himself. Besides the result ascertainable by weight, there are allowances and compensations to be made which are known only to an experienced assayer, and if these were disregarded, as might be the case with the mere novice, the report would be wide from the truth.

With regard to silver assaying, the chief principles in the process are—1. The power of lead to oxidate, or destroy the metallic property of the alloys, which it does by combining with them and sublimating them in fumes; 2. The absorbing power of the cupels in which the assays are made, and by which a great portion of the lead is taken up.

With regard to gold assaying, the same principles prevail in the preliminary process of cupellation, the result being a compound of gold and silver in their pure state. In the second process of *parting* the two metals, the first principle is the property of nitric acid to bring silver into a state of solution while it leaves gold untouched. The silver thus separated from the gold, which remains in a pure state, enters not into the calculation unless a parting assay is required, and therefore it is not recovered for any purpose connected with the art.

But before proceeding to the detailed description of the various delicate and interesting processes comprised in the art of assaying, we shall first describe the furnaces and implements formerly in use, as well as those changes and improvements which have been recently introduced and adopted, the result of experience and the promptings of scientific research, by which it may be said assaying has approached as near to certainty as can be expected in any chemical operation.

Assaying.

Description of furnaces, &c., formerly in use.

Plate LXXIV., A A A A, fig. 1, is a front elevation of an assay furnace; *a a*, a view of one of the two iron rollers on which the furnace rests, and by means of which it is moved forward or backward; *b*, the ash-pit; *c c* are the ash-pit dampers, which are moved in a horizontal direction towards each other for regulating the draught of the furnace; *d*, the door or opening by which the cupels and assays are introduced into the muffle; *e*, a movable funnel or chimney, by which the draught of the furnace is increased.

B B B B, fig. 2, a perpendicular section of fig. 1; *a a*, end view of the rollers; *b*, the ash-pit; *c*, one of the ash-pit dampers; *d*, the grate; *e*, the plate upon which the muffle rests, and which is covered with loam nearly one inch thick; *f*, the muffle in section representing the situation of the cupels; *g*, the mouth plate, and upon it are laid pieces of charcoal, which, during the process, are ignited, and heat the air that is allowed to pass over the cupels, and which will be more fully explained in the sequel; *h*, the interior of the furnace, exhibiting the fuel.

The total height of this furnace is 2 feet $6\frac{1}{2}$ inches; from the bottom to the grate 6 inches; the grate, muffle, plate, and bed of loam with which it is covered, 3 inches; from the upper surface of the grate to the commencement of the funnel, *e*, fig. 1, $21\frac{1}{2}$ inches; the funnel *e* 6 inches. The square of the furnace which receives the muffle and fuel is $11\frac{3}{4}$ inches by 15 inches. The external sides of the furnace are made of plates of wrought iron, and are lined with a 2-inch fire-brick.

C C C C, fig. 3, is a horizontal section of the furnace over the grate, showing the width of the mouth-piece or plate of wrought iron, which is 6 inches, and the opening which receives the muffle-plate.

Fig. 4 represents the muffle or pot, which is 12 inches long, 6 inches broad inside; in the clear $6\frac{3}{4}$; in height $4\frac{1}{2}$ inside measure, and nearly $5\frac{1}{2}$ in the clear.

Fig. 5, the muffle-plate, and which is of the same size as the bottom of the muffle.

Fig. 6 is a representation of the sliding door of the mouth-plate, as shown at *d* in fig. 1.

Fig. 7, a front view of the mouth-plate or piece, *d*, fig. 1.

Fig. 8, a representation of the mode of making, or shutting up with pieces of charcoal, the mouth of the furnace.

Fig. 9, a view of the cupel, which is generally 1 inch by $\frac{7}{8}$ths of an inch.

Fig. 10, the teaser for cleaning the grate.

Fig. 11, a larger teaser, which is introduced at the top of the furnace, for keeping a complete supply of charcoal around the muffle.

Fig. 12, the tongs used for charging the assays into the cupels.

Fig. 13 represents a board of wood used as a register, and is divided into 45 equal compartments, upon which the assays are placed previous to their being introduced into the furnace. When the operation is performed, the cupels are placed in the furnace in situations corresponding to these assays on the board. By these means all confusion is avoided, and without this regularity it would be impossible to preserve the accuracy which the delicate operations of the assayer require.

Figs. 14, 15, 16, 17, represent sections of a smaller assay furnace invented by MM. Anfrye and D'Arcet of Paris, called by them *Le petit fourneau à coupelle*, and which may be advantageously used by the experimental assayer. It is composed of a chimney or pipe of wrought iron *a*, and of the furnace B. It is $17\frac{1}{2}$ inches high, and $7\frac{1}{4}$ inches wide. The furnace is formed of three pieces; of a dome A; the body of the furnace B; and the ash-pit C, which is used as the base of the furnace, figs. 14 and 15. The principal piece or body of the furnace has the form of a hollow cylinder, flattened equally at the two opposite sides, parallel to the axis, and in such a manner that the horizontal section is elliptical.

The section of the furnace, fig. 15, presents several openings; the principal, which is that of the muffle, is placed in *i*; it is shut with the semicircular door *m*, fig. 14, and as is seen in the section *m*, fig. 15. In front of this opening is the table or shelf upon which the door of the muffle is made to advance or recede; the letter *q*, fig. 15, shows the face, side, and cross section of the shelf, which makes part of the furnace.

Fig. 19 is a plan of the grate of the furnace; and fig. 20 a horizontal view of it.

Figs. 21, 22, 23, are views of the muffle.

Fig. 24 is a view of a crucible for annealing gold.

Figs. 25, 26, 27, are cupels of various sizes, to be used in the furnace.

Assaying.

Figs. 28 and 29 are views of the hand-shovels used for filling the furnace with charcoal.

Fig. 30, the smaller pincers or tongs by which the assays are charged into the cupels.

Fig. 18, the teaser for cleaning the grate of the furnace.

Fig. 16 is a representation of the furnace first constructed by MM. Anfrye and D'Arcet, and which was worked by means of a pair of bellows, which forced a current of air through the brass tube *b*, entering the ash-pit under the grate at the circular hole *c*, fig. 15. The strength of the blast or current of air can be regulated at pleasure by the stop-cock *d*, fig. 16.

As the accuracy of the art of assaying depends in a great measure upon the construction of the furnace, as well as its management, and other implements and appliances, we proceed now to describe the improvements introduced recently in the Royal Mint by Mr H. W. Field, the Resident Assay-master of that establishment, which tend to secure greater accuracy, and allow of the processes to be conducted with greater economy. Instead of the expensive product, charcoal, being used in the cupellation-furnace, anthracite coal has been substituted; and the old sand-bath, employed to boil the acid, has been superseded by the use of gas.

In the furnace already described, figs. 1 and 2, the usual mode of lighting and feeding it is to throw the charcoal in at the top, igniting the fuel by means of a faggot of wood placed on the charcoal. In this manner two to three hours are necessary to raise the furnace to the required temperature to carry on the process.

In the new furnace, Plate LXXV, figs. 32 and 33, the fuel is ignited by a small quantity of live charcoal scattered round the sides and end of the muffle; and a few minutes having elapsed, the furnace is then filled up to the door, *h*, with anthracite coal, broken into fragments of about the size of a two-inch cube, and perfectly free from dust. The doors of the furnace should then be closed, excepting that of the ash-pit, and damper in the chimney, intended to give circulation to the air.

When the coal is found to be in a state of combustion, either the door at the top, *x*, or the furnace door, *h*, or both, should be opened, as experience may dictate; because it must be borne in mind that, after a certain point, if the heat were urged too suddenly, either the muffle would crack and be spoilt, or the bottom be too hot and the roof too cold, while at the same time clinkers formed in the furnace might impede the draught. If these simple precautions are attended to, and the heat gradually raised, the annealing of the muffle, cupels, and furnace will be uniform, and both trouble and expense avoided. By the use of anthracite coal, the process of cupellation may be carried on as successfully as by charcoal, when a saving is made of 550 per cent.

Description of new anthracite furnace.

Plate LXXV., fig. 32, is the front elevation of Mr Field's furnace; *a*, a view of the front iron-roller, on which it rests; *b*, the ash-pit; *c c* are the dampers moving horizontally from side to side towards each other, meeting exactly in the centre; *d*, the muffle-door by which the assays are introduced; *e e*, the door slides. So far the body of the furnace is similar to the old one, except that the bars on which the muffle stands run from front to back, and are movable, rendering the removal of the brick-work unnecessary. By this means the muffle stand is easily introduced, and having steady pins on the under side, it is raised about an inch above the bars.

The furnace measures 2 feet 10 inches in height; 1 foot 7 inches in width; and 1 foot 11 inches in depth. Instead of the furnace, as formerly, being fed at the top, the fuel is charged by the door *h*, which also affords the means of regulating the draught, and of throwing a current of air through the muffle by the door *d*. This door has a bar, *k*, traversing about two-thirds of it, running easily from the top towards the bottom within *i i*, with a ketch, *m*, on each side, to keep it close. These are made on an incline, and about 3½ inches long, so as to allow the traversing-bar to slide freely when the door is not required to be closed. In this manner the door may be opened from a quarter of an inch to the extent of three inches.

This feeding and regulating door is fixed by hinges, *l l*, to the front part of the *iron frame* covering the brick lining on the top of the furnace. On this frame rests the square dome, the front of which, *w*, is removable by two handles, *n n*; and by taking out the two thumb-screws, *o o*, the door and part of the frame come away, leaving a large opening, so as to enable the furnace to be cleared, the muffle repaired, &c.

The furnace should be placed in a recess under a chimney, with a movable iron ceiling, *t*, about one foot above the dome, fitting close in every part, so that the draught of air may pass through the furnace. A door, or flap, *x*, is attached to the iron ceiling by a hinge, opening on the side of the recess, with means to fix it at any point required, so that the current of air may be regulated by the operator: *s*, a swivel door affords another mode for damping the furnace.

Fig. 33 is a section of the furnace fig. 32: *a a*, the two rollers on which the furnace is placed; *b b*, the slides on which the ash-pit doors run; *c*, the door and ash-pit; *d*, the iron casing to the furnace; *e*, the brick lining; *f*, the ash-pit; *g g*, the two bars inserted in the brick lining, one in front, one at the back, support the furnace bars, which can easily be removed at pleasure; *h* shows one of the bars on which the muffle-plate rests; *i*, a movable tray on which the mouth coal is placed; *k* is a section of a muffle charged with its full complement of 50 cupels; showing also the rows of holes over each row of cupels, through which a current of air passes. Similar holes are placed at the back in three rows. They are not pierced through horizontally, but slope towards the ceiling of the muffle, at such an angle as to exclude the ashes; *l* represents the extra covering of fire-clay; *m*, the anthracite coal, showing the level; *n*, the feeding and regulating door; *o*, the ketch, or inclined plane on which the sliding bar travels; *p*, the door, with running staples in which the bar slides; *q*, the mode in which the movable front is brought round, and fixed by thumb-screws, *r*; *s v*, the hood; *t*, handle for removing the front; *w x*, the damper and handle; *y*, the iron ceiling.

Fig. 34 represents the upper internal view of the furnace bars, with the muffle stand or plate, showing also the space intended for the fuel.

Fig. 35 is the mouth of the muffle door, representing the mode of regulating the current of air by cylinders of charcoal. Fig 40 is the movable muffle door.

Fig. 38 is a representation of a muffle, 14½ inches long, 7½ inches wide, until it begins to taper at about 1½ inches from the front (see fig. 39), when it does not exceed 5½ inches. The height is 6½ inches, in the clear 5⅝ inches. Its sides are perforated with holes about a quarter of an inch diameter.

Fig. 36, an annealing-iron for softening the assays after they are flattened and rolled. It resembles a square box of iron about ⅛th of an inch thick, having strengthening pieces rivetted at each end, and two in the middle, *b b b' b b*, between which are receiving places for the assays, *a a a*. The apertures are made diagonally, as shown by *c c c*, that the assays may not fall completely to the bottom of the box, so that they may be conveniently removed. The under part of the box has a kind of double keel, *d*, rivetted on it, so that in taking it from the furnace there be no danger of upsetting it on the *nealing trident*.

Fig. 37 represents the trident for removing the annealing-iron from the furnace.

Gas apparatus.

Fig. 41 is a view of the apparatus for boiling the gold assays in acid. Though, it may be remarked, there is no peculiar novelty in boiling by the agency of gas, this is a very useful and ingenious application of the principle; and, we may add, that the apparatus here represented, constructed by the Assay-master of the Royal Mint, is superior to any in use. By it 45 gold assays can be operated upon at the same time, but its greatest advantage is the perfect control which it gives to the assayer over the process, by which great uniformity in the result is obtained.

The whole apparatus, with the exception of the wooden feet and slips upon which the flasks rest, is constructed of brass, and consists of three tubes, *b b b*, firmly fixed at each end to two sides of mahogany, *a a*, by screws: each tube has a cap *h* soldered thereon, with small stopcock; the other end is open, in order to secure its connection, by a vulcanized india-rubber tube, with three fixed pipes having stop-cocks; and these pipes again unite in one main pipe, also furnished with a cock.

From the end of the front and back tubes or bars, *b b*, rise the metal pillars *g g g g*, to which are attached the inclined supports *k k* on each side, having notches for the movable bars *f f f*, which are so arranged as to allow the operator to see over each bar the row of burners behind it, as well as inspect the ebullition of the liquid. From the three tubes or bars *b b b* rise the gas-burners, *c d e*, each row being fixed at a distance sufficient to allow the flasks when resting over the burners and against the movable bar to be secure from falling. The burners have each a separate stop-cock, and as the tubes, or bars, are arranged at different heights, the highest being in front, the operator can easily reach the stop-cock of any particular burner, or, if necessary, a key can be applied.

Assaying.

The movable bars *f f f* have cross handles at each end to remove them, and on the front of the bars a piece of wood is screwed, having semi-circular notches exactly opposite each burner in which the neck of the flask rests, while the body of the flask is supported over the burner by brass rings passing through the bar above, attached and fixed by thumb or milled screws, thus affording the means of adjustment as to distance from the burner, &c. These particulars may be seen by a reference to fig. 42, *a b c d*.

Fig. 43 is a section of the apparatus; *a*, the wooden stand; *b b b*, the three tubes or bars by which the gas passes to the several burners; *g g*, the pillars, rising from the front and back bars, which at *h h* hold the sloping notched supports *k*, for the movable bars *f*; *c, e*, faintly indicate the burners; *d*, the middle line of burners, showing also the stop-cocks, with the rings supporting the flasks over the flame; *m m*, the notches for front and back movable bars; *f*, the handle to the bar to which the ring supports are fixed by screws.

Fig. 44, a tray for the flasks when charging the acid, or washing the assay.

Fig. 45, tray to stand in front of the operator in case one or more flasks require to be removed before the whole are sufficiently boiled.

Fig. 46 represents a stand for holding the movable bars when taken from the apparatus to charge the acids or otherwise.

Fig. 47 shews a burner unscrewed from the bar.

Fig. 48, the wire support.

Fig. 42, a portion of a movable bar; *a*, a burner; *b*, part of supporting bar; *c*, a flask; *d*, rings for carrying flasks.

Fig. 49, a glass-lipped vessel in which the acid is placed before filling the flasks. *b*, a *pipette* by which an equal quantity of acid is supplied to each flask.

By this description, the mode of working may be easily seen. The movable bars are first charged with the flasks containing acid. The three small cocks *h h h*, at the end of the tubes, are then opened, for speedy escape of the air; next the main or chief cock; and then the other three cocks communicating with the tubes. Each individual burner can be regulated by its own stop-cock, the whole tube by its cock, and the whole apparatus by the main.

Having thus fully described the various implements in use amongst assayers, without which the process could not be conducted with any practical utility, it is necessary to make some preliminary observations here with regard to the lead, cupels, &c., before the operation of the assay commences. The cupels are made of the ashes of calcined bones, or phosphate of lime, and besides being uninjured by the ordinary heat of an assay furnace, they possess the peculiar property of absorbing the lead used to refine the silver. Hence the term *cupellation* applied to the process of purifying gold and silver by fire on cupels.

The cupels are formed in a circular mould made of forged steel, nicely turned, by which means they are easily freed from the mould when struck. The bone-ash being moistened with a quantity of water, just sufficient to make the particles adhere, is put into the mould and pressed down level with the surface. It is then struck with a pestle or rammer, smoothly turned and polished, the end being of a convex shape, and of the exact size of the cupel required. (See Plate LXXV., figs. 50 and 51, the section.) This concavity forms the cup in which the assay is made. These cupels are allowed to dry in the air for some time before they are used, and are annealed in the furnace before the assay is charged in.

The lead used in cupellation should be of the greatest purity, because, as most lead contains a small portion of silver, this silver would necessarily combine with the assay, and vitiate the accuracy of the result. Lead revived from litharge is supposed to be the purest, as it contains scarcely any silver. Another important consideration in the process of assaying is the *quantity* of lead to be used with each assay, but such information can only be acquired by experience; for the assayer must first ascertain the approximate quality of the metal to be examined before he can determine the amount of lead necessary.

This in ancient times was effected by the use of what were called *touch-needles*, or slips of metal composed of pure silver alloyed with definite proportions of copper in a regularly-increasing series. The silver to be assayed was examined in comparison with these touch-needles in colour, tenacity, and other external characters, and its alloy was estimated by that of the needle to which it showed the closest resemblance. These needles are now seldom used, the assayer relying on his general experience for the quality of the metal. Having ascertained this point so far as is necessary, he apportions the lead deemed requisite (ranging from 10 to 20 times the weight of silver), which is first flattened into a thin plate from small bullets cast for this purpose.

Assaying.

Silver assaying.

We will now proceed to describe and explain the process of assaying silver by cupellation.

The small specimen of silver sent to an assayer cut from the bar to be valued, usually weighs from 3 to 4 dwts.: it is folded in a slip of paper on the head of which is written the date, the mark or number of the bar from which it was severed, and the kind of assay required. This piece is flattened upon a polished anvil by means of a hammer, which should be examined and freed not only from dirt but from any particles of metal flatted from previous assays. From the silver, thus flattened to about the $\frac{1}{25}$th of an inch thick, the centre portion is cut out, as being the most compact, and is then adjusted in a "preparing balance," by cutting and filing to the weight of what is technically denominated the "assay pound." After this preliminary weighing, it is then weighed most accurately in one of the superior balances.

At this stage of the operation it is necessary to ascertain the approximation to purity of the metal, so that the proper amount of lead be added; but, as we have before remarked, practice alone can guide the assayer in this particular. The chief indications relied on are the specific gravity, colour, and even sound; for the purer the silver is the less it rings, while at the same time whiteness, softness, ductility, and superior gravity are tokens of purity; but, on the contrary, when sonorous, yellow, and specifically light, it may be inferred that the metal is base in the degree that these peculiarities are indicated.

The amount of lead having been determined, the assay is wrapped up in a known quantity (say one-half of that required for its purification), formed into a case somewhat resembling a thimble, great care being taken to make the joints firm and close, so that no particle of silver shall escape. When a number of assays are made at the same time, they are arranged, enveloped in their cases of lead, on a board divided into compartments, corresponding in number and position with the cupels into which they are intended to be charged. As the assayer makes generally two or more trials of the same piece, so that great accuracy may be secured, it is his practice to give one assay a side place in the muffle, and the second a middle one, in order to check any irregularity in the result.

When a sufficient number of assays are weighed, and arranged upon the board, in the manner referred to, and the furnace raised to the necessary point of heat as well as the cupels, the charging tongs are then taken, and the *rest* of the lead apportioned to each assay placed individually upon the cupels, beginning at the back of the muffle. The lead added in this case is not flattened, but a piece or bullet of known weight, various sizes of which, as well as cases, are kept in stock by the assayer. The lead so placed in the furnace rapidly melts and becomes covered with a grey oxide, but soon after appears fluid and brilliant; and at this point the assays are charged by means of a pair of tongs, great attention being given that no part overhang or touch the edge of the cupel. The assays are thus drawn into the mass of molten lead, and any particles of silver are in this manner prevented from adhering to the sides of the cupels in charging; sufficient despatch being used to obviate the fusion of the assay in its transition. The assays being charged in order on their respective cupels, and the furnace

previously filled with fuel, cylinders of charcoal, about six inches long, are inserted in the mouth of the muffle, so as to fill up the orifice in the furnace. The object of this is, that the stream of air admitted to pass over the surface of the cupels, and which is necessary for the rapid oxidation of the lead, may not chill the muffle and retard the progress of the assay. By displacing one or more of these pieces of charcoal, the assayer can increase the current of air, while at the same time he is enabled to inspect the operation as it proceeds.

In the first instance, dense fumes will be observed to rise from the melted metal, indicating the oxidation and subsequent volatilization of the lead. These continuing some time are then followed by the appearance of small luminous points on the surface, which increase in size and brilliancy as the operation progresses. And then a minute stream of red fused matter is seen to flow from the top of the silver globule, and circulate around it, which is carried down and absorbed by the cupel. This arises from the vitrifaction of the lead by the air, which at the same time oxidates the copper.

As the cupellation advances, the fumes gradually lessen in density till they disappear altogether. The melted button at this stage is observed to become more convex and round; and as the last vestiges of the lead and alloy are being carried off, it assumes a cloudy appearance on the surface, changing to large bright points of the fused oxide, till at length it is nearly freed from all impurity. At this point the noble metal displays some singular and beautiful characteristics. Deprived of all the base alloys save the last minute portion that tarnished its lustre, it has become bright and pure, and gives forth from its surface irridescent circulating rays of light, which indicates the successful completion of the process.

During the operation, the assayer's attention should be directed to the heat of the furnace, which must be neither too hot nor too cold: if too hot, minute portions of silver will be carried off with the lead, and so vitiate the assay; moreover, the pores of the cupel being more open, greater absorption will ensue, and there is liability to loss from that cause. One indication of an excess of heat in the furnace, is the rapid and perpendicular rising of the fumes to the ceiling of the muffle, the mode of checking and controlling which has been pointed out in the description of the improved furnace.

When the fumes are observed to fall to the bottom of the muffle, the furnace is then too cold; and, if left unaltered, it will be found that the cupellation has been imperfectly performed, and the silver will not have entirely freed itself from the base metals.

The white, or dark appearance of the cupels, may also afford some guide to the operator; but in such cases practice and experience are the best instructors; and it is not possible, in a general description, to measure out the precise degree of heat necessary to the perfection of the process.

The cupellation completed, great care is required with regard to the cooling of the globules, for if that process be not allowed to take place gradually, they will "spring" or burst, and throw out particles of pure metal from the interior. This arises, as is generally supposed, from the exterior portion cooling too rapidly, which forms a sort of shell that, shrinking as it cools, presses on the still liquid fluid and makes it spurt out; but others have suggested that the cause of "springing" as it is called, is to be attributed to the disengagement of a small portion of oxygen combined with the melted silver.

The globules being cool are removed from the cupels with a pair of pincers, and struck on the edge with a hammer on the anvil, in order to remove any oxide or extraneous matter adhering to the under surface, and are further cleaned with a "scratch-brush," made of fine wire bound firmly together. After this, having been carefully placed in their compartments, they are weighed with the greatest nicety, the loss in weight indicating the amount of alloy abstracted; and affording the *apparent* quantity of pure metal in the pound. But into the assayer's calculation certain considerations enter, derived from long experience and observation during the process, which make the actual result of the assay button only an approximation to the actual quality of the metal under examination. For, supposing the operation to have been perfectly performed, he finds it necessary, for example, to make some compensation for a certain amount of silver, not lost, but absorbed in the cupel itself, which he knows to have been abstracted from the assay.

Assaying.

This fact may be ascertained by reviving the oxide of lead from the cupel, and cupelling the lead by itself, when it will be found that the small globule of silver left on the cupel considerably exceeds the proportion of this metal in the lead, and will correspond nearly with the loss of silver in the assay. And it is manifest, therefore, if this were not taken into calculation in the assayer's report, the metal would appear less pure than it really is, all deficiency of weight being reckoned as alloy. It has been calculated, that when no more lead is used than is necessary to separate the alloy, there is carried down into the cupel as much silver as, when the whole is again reduced, would make the noble metal $\frac{1}{128}$th of the mass, when the natural admixture of the silver is only $\frac{1}{1152}$d. But if an excess of lead be employed, this loss of silver is somewhat greater, though it does not increase in the ratio of the excess of the lead.

French chemists, who impugn the accuracy and scientific nature of the process of cupellation as applied to the assay of silver, have generally adopted another very ingenious and delicate mode, called "*La voie humide*," or humid method, in contradistinction to the dry. This system is maintained to be more certain and accurate in its results by the French, but as English assayers are divided upon the point, it is not generally practised, and therefore we need not enter elaborately into a description of it.

This ingenious process was originally discovered by M. Gay-Lussac, the distinguished French chemist, by whose influence it was introduced into the Paris Mint and other establishments. In his "*Instruction sur l'Essai des matières d'Argent*," it is thus described:—"Le nouveau procédé d'essai que nous allons décrire consiste à déterminer le litre des matières d'argent par la quantité d'une dissolution de sel marin titrée, nécessaire pour précipiter exactement l'argent contenu dans un poids donné d'alliage."

The metal being dissolved in nitric acid, a quantity of salt is poured into it from a graduated vessel till the whole silver is precipitated in the state of chloride, a compound insoluble in water or even in acid. The quantity of chloride of silver precipitated is determined, not by weight, which would render the process tedious, but by the weight or the volume of the dissolved salt necessary to precipitate precisely the silver in the acid. The complete precipitation of the silver is easily recognized by the cessation of the cloudiness in the liquid, when the solution of salt is gradually converted into nitrate of silver In this process the presence of copper, lead, or any other metal in the solution of silver, does not in a sensible degree affect the quantity of salt necessary to the precipitation; that is to say, the same quantity of silver, whether pure or alloyed, requires a fixed and constant quantity of salt to effect its separation from the acid.

Though the theory of the process appear thus so extremely simple, in the practice of it, nice manipulation, and long experience as to the presence of other metals equally affected by the salt, are absolutely necessary; and these have carried it to such perfection that the results can be obtained with as much rapidity, and, *according to its advocates*, with more certainty and confidence than by the ancient mode of cupellation.

Silver parting assay.

It remains for us now to notice briefly the *silver parting assay*, or that by which the amount of gold contained in silver is discovered and determined: an assay which has become very common in modern times, in consequence of the discovery of the art of refining by sulphuric acid, whereby gold can be separated from silver at a comparatively small cost.

The button or globule resulting from the cupellation of the silver is simply digested with nitric acid in a glass bottle, or matrass, on a sand-heat, and the acid taking up the whole silver, leaves the gold at the bottom in the shape of a fine brown powder. The acid being poured off, the residuum is washed in warm water, and then allowed to fall into a small clay-vessel, or crucible, in which it is brought to a red heat, in order to expel any moisture. The weight is then ascertained, and the gold being deducted from the silver, shows the proportion of each metal in a given weight. The report of this assay is stated as follows:—B. 15 dwts. for silver; gold 12 grains per pound Troy. When the amount of gold exceeds one-quarter of the assay-specimen, or $\frac{25}{100}$ths, it is found necessary in practice to treat it as a gold assay.

Gold assaying.

We proceed now to describe the process of assaying gold, which, as greater values are affected, demands even more care and attention than that of silver.

The preliminary process exactly resembles the one already described, the object of cupellation in this case, as in the other, being to destroy the base metal or alloy contained in the gold. If gold contained only copper as alloy, the assaying of gold would be as simple as that of silver, the globule of fine metal on the test indicating by weight the quality of the specimen operated on, as in the case of silver. But as gold generally is found to contain a portion of silver in combination, and as silver is not destroyed by cupellation, it will be manifest that another process is required to separate the silver from the gold. To effect this object recourse is had to the "*parting process*." This is done by means of nitric acid, which entirely dissolves the silver, and leaves the gold perfectly pure. But as gold does not commonly contain sufficient silver to allow of the action of the acid and complete dissolution of the silver, it is found necessary in all gold assays to add from 2 to 3 parts of fine silver on the cupel. In this manner the particles of gold are disseminated, and no longer protecting the silver from the acid, the dissolution is easily accomplished.

In the first stages of the operation the same remarks are applicable as were previously made on the assay of silver. The specimen to be examined is rolled or hammered out, and a piece taken from it free from extraneous matter; it is then nicely weighed against the integer, or *assay pound*, the assayer exercising his judgment on the metal as to its various characteristics of colour, &c., so as to determine the addition of pure silver necessary, with other alloys, to effect the solution in boiling acid, the proportion required being full $\frac{2}{3}$ds of the whole.

The silver added is then placed with the gold assay in a case of lead weighing half that necessary to complete the process; and if there be a number, they are arranged on the board as formerly described, ready to be charged *seriatim* into the cupels prepared in the furnace. The remainder of the lead is then added, and the process of cupellation proceeds as before.

The assays having passed the cupel successfully, they are flattened on a polished anvil, three well-directed blows with a heavy hammer being sufficient to reduce them to the proper form and thickness to pass through the flatting-mill. This is worked by hand, and reduces the pieces to thin plates or laminæ about $\frac{1}{30}$th of an inch thick, which are annealed or softened, and, to avoid confusion, they are placed on the "annealing iron" (fig. 36), from which they are taken one by one and carefully rolled up with round-nosed pliers, in such a manner that the acid may penetrate between each fold. They now resemble coils of silver, and are ready for the parting process.

From time immemorial *sand-baths* have been used for boiling the acid, deemed the safest and best for matrasses or bottles of glass, liable at all times to break by undue expansion caused by the sudden and irregular application of heat. But as gas in modern times has been applied to many useful purposes, so amongst others it has been successfully employed in boiling the parting assays.

The *sand-bath* is a somewhat clumsy contrivance, consisting of a square copper pan covered with fine sand about an inch in depth. This is placed over an open charcoal fire, and three-quarters of an hour are required to properly heat the sand. Flat-bottomed, conical glasses, containing the assays and acid are placed on the bath, and the liquid allowed to boil; and by changing the glasses from time to time, so as to equalize the ebullition of each, very satisfactory results have generally been attained. But this plan has been recently improved upon by Mr H. W. Field of the Royal Mint, by the introduction of his apparatus by which gas is used to boil the acid, and which is effected more expeditiously, with as much safety, and with more economy. This apparatus will be seen by reference to fig. 41 to 49. Plate LXXV.

The flasks or bottles which are round-bottomed, lighter, and more tapering than the old matrasses, are placed on the gas-jets, and in five or ten minutes the acid is hot enough to receive the assays. By means of this 45 assays can be operated upon at the same time. The assays being charged, the acid is seen instantly to attack the alloy with great vehemence, which becomes oxidized by abstracting a portion of oxygen from the nitric acid, giving forth at the same time dense nitrous fumes. So long as these dark red fumes are visible the decomposition continues, but gradually they become fainter and fainter, till they disappear altogether. Lest some silver remain in the gold, protected from the action of the acid, the liquid is decanted, and its place supplied by some stronger acid, of the specific gravity of 1·35. This removes effectually any particles of alloy that may be incorporated with the gold.

In this process, the assayer's attention should be chiefly directed to the strength of the acid; for if it be too strong the cornet of gold is liable to be broken and reduced to powder, rendering the subsequent collection of the grains a work of difficulty; if too weak, a portion of silver or alloy will remain incorporated with the gold, and vitiate the accuracy of the assay. The specific gravity of the acid applied in the first instance should be about 1·2, three or four times the weight of the assay being added; in the second boiling, it should be about 1·35; but experience will be found a safer guide in such particulars than any definite rules. The principal object is to employ acid of the exact strength that will, after the silver has been extracted, maintain the cornet unbroken and of a spiral form. Regard must also be had to the proper proportion of silver added to the assay; for if that be in excess, the nitric acid is liable to reduce the gold to powder.

When the acid is in the act of violent ebullition, the assay will be found to rise in the glass and strike against it, and in order to prevent this the French assayers generally put into the liquid a piece of charcoal about the size of a pea, which forms a kind of nucleus, around which the acid boils; but this application, however simple, discolours the acid and renders it useless. At the Royal Mint, in lieu of charcoal, the assayer uses small porous clay balls about $\frac{1}{8}$th of an inch in diameter, which have not that objection, and being washed in boiling water after use they can be employed again and again.

Before the cornets are removed from the glasses, the hot acid is carefully decanted, and the flasks filled with warm distilled water, so as to wash away the remaining acid, and any residue of silver. This should be repeated until the

liquid is seen to pour off perfectly clear. After this, the flasks being filled with water, they are one by one inverted over a small clay annealing pot, and the cornet of gold is allowed to fall gently through the water into the pot. These vessels are arranged in such a manner as to obviate any confusion, and secure the identification of the assay. The superfluous water being poured out of the pots, they are then placed in the furnace and annealed under a bright heat.

The cornets, by the action of the acid and by the separation of the silver, are thoroughly corroded, though their original form remains unaltered. They are in this state extremely brittle and porous, and when examined microscopically appear to resemble a very fine sponge. They bear a nearer likeness to pieces of brown earthenware than to gold. But after annealing, they regain all the properties of that truly noble metal; and being allowed to cool, they are carefully weighed against the assay pound, and the diminution of weight recorded. If they are weighed hot, it has been ascertained that a variation will occur of nearly ⅛th of a carat grain, and, therefore, such an error should be guarded against.

It is a matter of the greatest importance that the silver used in this process should contain no gold, otherwise a source of very material error would arise in the delicate operations of the assayer. The silver cannot be too pure, and a careful examination should be made of it before employing it for that purpose. The most certain mode of attaining that object is to precipitate silver from the nitrate, which cannot possibly contain any gold.

As in the case of the silver assay, certain compensations are found by experience necessary before an accurate report can be made of the gold assay. In the cornet it must not be supposed that we have before us an assay perfectly pure, as a previous paragraph may have suggested, or that no loss of precious metal has taken place during the process. Notwithstanding all the care and attention used by the assayer, it has been discovered that the cornet is not altogether free from silver; and it is manifest if this were not allowed for, the report would declare the gold to be finer than it really is. The amount of silver so remaining is estimated by the Mint Assayer to range between 4 and 9 grains Troy. But in this particular it is probable no two assayers will agree, as the allowance to be made depends on the practice of each. And what is gained to the assay by silver, is to some extent lost again, in the cupel and by the action of the acid. For, by the experience of Mr Field, an assayer of long practice, nitric acid does take up a small portion of gold, contrary to the general notion of chemists; which has been proved by laying aside the second or strong acid (employed more than once) in a conical-shaped bottle where it was permitted to remain. After some time a coating of gold was apparent at the bottom of the glass, and under the influence of light the whole interior of the bottle was coated up to the stopper when the acid reached so high.

Two bottles of acid that had been repeatedly used to digest gold assays for some years, yielded in this manner full 30 grains of gold. This fact has recently been confirmed by experiments made by Mr C. Sterry of the Mint, and also by that careful chemist and assayer Mr G. H. Makins of London.

Independently of these allowances and compensations, another must be made for variations caused by the particular process itself, as indicated by the trial piece put into the furnace along with the assays, and which in all respects passes the same ordeal. This standard piece of metal consists of a certain weight of gold of a known quality, and whatever variations it undergoes, the assays themselves are supposed to be subject to the same.

Gold is found to contain other metals beside silver and copper, such as platinum and the allied metals; and when that happens the assayer has to exercise his judgment in ascertaining the character of the metal and its amount. In ordinary cases, when the assay after cupellation contains gold and silver only, it assumes the appearance of silver; but if platinum be combined with it in any notable proportion, it will easily be detected by the crystalline surface of a dead white colour, covered with bright rough points; if palladium, the button assumes the appearance of an ordinary assay, but in the final clearing of the assay in the furnace it resembles an assay cooled too quickly; and while it tinges the acid a deep rich red colour, the former is marked by a pale yellow. Again, if iridium be in combination, it will mix mechanically with the gold in metallic grains; but, after passing through the fire, it will leave streaks of black powder on various parts of the cornet.

Assaying.

Small portions of platinum and palladium are removable by the acid; but, as iridium is insoluble in any acid, no means have yet been devised of separating it from the gold in the process of assaying.

Gold parting assay.

The "gold parting assay" is simply the process by which the silver is separated from the gold, so as to enable the assayer to report the contents, that the bullion-holder may realize the value. This is effected by dissolving the silver in the nitric acid, as before described in the common assay, and then ascertaining the amount of silver resulting in excess of the quantity used in the process, which indicates the amount of silver contained in the assay pound, and by computation in the Troy pound.

The gold coming from Australia, and particularly from California, is found to contain a considerable amount of silver, which can be separated easily and economically by the sulphuric acid process of refining, and recently this branch of assaying has also augmented far beyond what was required in former times.

The silver in solution resulting from the parting assay may be precipitated in the metallic state, by diluting the liquid with water, and then putting into it plates of copper. The silver being thrown down and washed carefully until the water be nearly tasteless, may then be dried and melted. This method, however, is considered offensive, because, in the action, there is a copious discharge of dark red noxious fumes of nitrous gas.

The plan now pursued by the Mint Assayer is to throw down the silver in solution as a chloride, by the addition of either common salt or hydrochloric acid, until all cloudiness disappear. The residuum is then collected in proper earthen pans, well washed, and slightly acidulated with hydrochloric acid, immediately immersing in the liquid plates of iron, which reduces the chloride to a metallic state. The plates are then taken out, and the silver first washed with hot water, containing a little hydrochloric acid, and then repeatedly with hot-distilled water till it pours off tasteless. The powder is then dried and melted.

In conclusion, we append a table of the gold assay weights, and their corresponding decimals; premising that in a few years the decimal system will probably supersede the ancient complex mode of notation.

Carats.	Carat Grains.	Eighths.	Troy Weight. lb.	oz.	dwt.	grs.	Decimals.

Assaying. Assay-balance.

A description of the process of assaying might be deemed incomplete without some reference to the assay-balance, which may be said truly to constitute the right hand of the assayer, and on the delicacy and accuracy of which depend, in a great measure, the truth of the results. With that view, we may be allowed to give a detailed description of a beautiful and ingenious balance recently adopted in the Royal Mint, constructed on improved principles by Mr G. H. Makins, practical Chemist and Assayer, Coleman Street, London, and manufactured by an excellent workman, Mr Oertling of Store Street. It seems to combine all the advantages of modern improvements, both in design and workmanship, and in practice must amply fulfil the most sanguine expectations of the inventor.

In a good assay-balance three essentials are indispensable,—1. It should be quick in its action; 2. It should be constant and uniform—that is, oscillate to the same point of the index with the same weight to any number of weighings; 3. It should be extremely sensible and delicate, indicating the minutest shades of difference. As, however, the sensibility of a balance is found to diminish as the quickness of action is increased, the centre of gravity being lowered, one of the excellencies of the balance alluded to consists in the nice adjustment of these two opposing qualities.

The beam is what is generally called a skeleton-beam, 10 inches long, $\frac{1}{2}$ an inch deep at the fulcrum, tapering off at each end to the $\frac{1}{3}$d of an inch. At the centre it is about $\frac{1}{10}$th of an inch in thickness, decreasing at the ends to the $\frac{1}{20}$th of an inch. The weight of the beam is only 85 grains; and therefore it contains little more metal than is necessary to secure the several parts together at the points of suspension.

The end adjustments, indicated by *a*, in fig. 52, Plate LXXV, for the length of arm, are similar to many other delicate balances, namely, a saw-cut with screws, to open and shut by pressure. The pendants, *b*, at each end, are supported by two hard steel-points, *c*, having a fine screw cut on each, with nuts to fix them, so as to obtain a perfectly straight line, touching all the points of suspension. These pendants or pans, *d*, with the skiffs, *e*, are hung on these points by means of steel-plates, having a cup-shaped cavity for the one, and a groove for the other. It would be impossible for the most skilful workman to form two cups so accurately as to *plumb* or adjust themselves with mathematical precision to the points of suspension.

As the weight used with this balance rarely, if ever, exceeds 20 grains, the parts of contact where friction occur have been reduced to mere points, and in consequence the wear is very slight.

One peculiarity of this balance is the use of a weight called a *rider*, represented by *f*, supposed to be a German invention, which is placed or rests on the beam itself, and depresses it; the beam being divided in its length into ten parts, and the rider placed on any part, the weight is ascertained, and thus allows of an easy and simple mode of weighing decimally. The rider, *f*, is carried from one point or division of the beam to another, or may be altogether removed by a movable arm, *g g*, worked by the hand from the outside, *h*, of the case or lantern. It travels or traverses the beam on a stage, *i*, fixed from side to side of the lantern at *k k*; and in this manner the small or fractional weights may be ascertained without subjecting the beam to disturbance by the admission of air upon opening the glass-door, *l l*, of the case B.

A, represents the outline drawing of the balance and apparatus; the supports being of massive construction in order to obviate any tremulousness. They consist of two pillars, *m m*, fixed on a base, *n*, and on the top of these columns a table is fixed, *o*, with two upright pieces, *p p*, rising from it, to which are attached the agate bearings, formed of an elliptical shape, and presenting therefore the smallest points of contact to the knife edges. A corresponding table, *q*, is fixed to the rods, *p p*, which move up and down the pillars, *m m*, and by means of the lever handle, *r*, give action to the beam. The table has two mortices in it exactly fitting the upright pieces, *s*, which carry the agate-bearers, and upon these uprights the table slides up and down. On the outside of this second table, *q*, is a crutch or Y, *t*, which raises the beam from its bearings when it is thrown out of action.

The beam, on being depressed, acts first upon the arms of two rollers, fixed under the lantern, whose opposite arms depress the ivory tables supporting the pans; and at the point when the tables are free, the lever has reached a connecting stirrup between the movement rods, and then begins to lower the beam upon the agate bearers. The tops of the ivory tables that support the pans are of a spherical shape, *v v*, fixed upon the tables *w w*, so as to admit of the least possible contact; and the pans have the curve of a radius exactly equal to the distance between the ivory table and the point of suspension; so that, if they are found to swing out of the perpendicular during the act of weighing, they will be caught by the tables when they rise upwards; *y y* are spirit-levels.

In this balance there are adjustments for the amount of fall of the fulcrum to the agates, as well as for the rise of the ivory-tables to the pans; but the former is small in amount. The pillars being placed at the distance of $1\frac{1}{2}$ inch apart, and the index-needle, *x*, long—extending 6 inches downwards—a good scale of division is obtained; while the motion of the index-needle being nearly level with the pans, a great advantage is secured in use. (R. M—T.)

Asselyn || Assemani.

ASSELYN, Hans, a distinguished Dutch painter, was born at Anvers in 1610, and became the disciple of Esaias Vandervelde, the battle-painter. He distinguished himself in historical painting, battles, landscapes, and animals, particularly horses. He travelled into France and Italy, and was so pleased with the manner of Bamboccio that he always followed it. He was one of the first Dutch painters who introduced a fresh and clear manner of painting landscapes in the style of Claude Lorraine; upon which all the painters imitated his style, and reformed the dark brown they had hitherto followed. Asselyn's pictures were in high esteem at Amsterdam. He died in that city in 1660. Twenty-four pieces of landscapes and ruins, which he painted in Italy, have been engraved by Perelle.

ASSEMANI, the surname of three learned Maronite Syrians, who flourished in Italy in the last century. The eldest, and the most learned of the three, *Giuseppe Simone*, was born at Tripoli in Syria, in 1687. Having been sent to Rome to receive a classical education, he soon distinguished himself by his learning and industry, and was chosen by Pope Clement XI. to go and visit the convents of Egypt and Syria, in search of ancient MSS. with which to enrich the library of the Vatican. He executed his commission with great success, and in reward for his services was made archbishop of Tyre, and librarian of the Vatican. His principal work is his *Bibliotheca Orientalis Clementino-Vaticana*, in 4 folio volumes, 1719–28, which contains valuable biographical notices of Syrian Christian authors. He also published, in 6 vols. fol. (Lat., Greek, and Syriac), 1732–34, the works of St Ephraem, a Syrian father of the Church. He died at Rome in 1768 at the age of 80. *Stefano Evodio*, his nephew, was created bishop of Apamea, and succeeded his uncle as librarian. He also published two folio volumes of Oriental Catalogues of Vatican MSS. and other archæological works of merit. *Simone*, the grand-nephew of Giuseppe, born at Tripoli in 1752, was long professor of Oriental languages in the University of Padua, where he died in 1821. He is best known by his masterly de-

tection of the literary imposture of Vella, a pretended history of the Saracens in Sicily, which was confirmed by the German Hager.

ASSEMBLY. This word, besides its well-known social application to meetings for purposes of conviviality or gaiety, is a term by which important political and ecclesiastical bodies have become known in history and jurisprudence. The original use of the term is in the French *Assemblée.* It is applied in early history to those *Assemblées du Champ de Mars*, or *Assemblées de Mai*, of which the historical notices are so uncertain that they are not clearly distinguishable from the meetings of the States General or great vassals of the crown. On the occasion of the meeting of the States General in 1789, a memorable use was made of this dubiety of expression, and the term National Assembly was applied to the assemblage, when the third estate or commons revolutionized its character by resolving to sit and act whether they were joined by the other orders or not. Of the history of this body a full account will be found under the head of FRANCE.

The application of the term *Assemblée* in France to the meetings of the clergy, elsewhere generally called councils, is evidently the source of its transference to Scotland, through Knox's intercourse with Calvin. The General Assembly thus became the fixed designation of the supreme collective council, legislative and judicial, of the Scottish Church. The first Assembly, when the system was of course but imperfectly developed, was held in 1561. In the subsequent ecclesiastical contests, of which an account will be found under the head of SCOTLAND, it was the object of the Presbyterian party, in opposition to the Episcopalian party and the crown, to vest a supreme and independent authority over ecclesiastical affairs in the General Assembly. In the memorable Assembly held at Glasgow in 1638, this supremacy was for a time accomplished; and after having abolished the Episcopal hierarchy, the body continued to sit and act after it had been required by royal authority to dissolve. It was the principle of Cromwell's government to tolerate the various Protestant communities in their worship and ordinances, but not to permit any of them to assemble in deliberative bodies. Those who vindicate his policy hold, that when ecclesiastical disputes are merely local, the influence of the victorious majority in one place is neutralized by the superiority of its opponents in another; while, if they were permitted to meet and fight pitched battles, the stronger party would crush or drive out the weaker. During the Commonwealth, this view was in some measure confirmed by the existence in Scotland of two opposite clerical parties, which, though denouncing each other, never afforded an opportunity by meeting in assembly for a critical trial of strength. At the Restoration, the suppression of the Assembly was continued on different grounds. Along with the inferior church judicatories, it was restored at the Revolution. William III., however, and his advisers, by no means admitted the claims of entire independence of the state claimed for the church, and more than once a contest appeared inevitable. He was accustomed to convene and dismiss the Assembly at his pleasure. At all times the Scottish church has denied this power to the royal prerogative, but methods were found for avoiding a discussion of the point. It came to be the practice for the Assembly to meet and separate on certain established days; and by a device adopted soon after the Revolution, the royal commissioner, in the name of the sovereign, adjourns the Assembly on its last stated day of meeting to the stated day for recommencing; and the elected moderator, without appearing to notice this proceeding, makes identically the same adjournment, solemnly proclaiming it in the name of "the Lord Jesus Christ," as the Head of the Church. The Assembly consists of representatives, clerical and lay, from the several presbyteries of the church, and of a few other members. It is a general characteristic feature, that the clergy are always the majority. When the Free Church separated from the Establishment in 1843, it constituted a General Assembly on the same principles; and, being a voluntary church, has not of course been embarrassed by any questions with the crown. The several bodies of dissenters from the Church of Scotland, who became combined together as the United Presbyterian Church, give the name of Synod to the general aggregate body of their members, corresponding with the General Assembly in the other Scottish Presbyterian bodies.

The Westminster Assembly of divines was a memorable and important adoption for a short period in England of the Scottish system. It was the creature of that remarkable influence exercised by the Scottish party ere the Independents and the army had asserted their preponderance. It followed the victories of the Scottish arms, and those exhortations of the covenanting preachers in London which obtained so much attention and popularity in the eventful epoch of the conflict between the parliament and the crown. In the negotiations conducted at Oxford in 1643, one of the bills to which the royal sanction was demanded, was termed "A bill for calling an assembly of learned and godly divines and others to be consulted with by the parliament, for the settlement of the government and liturgy of the Church of England, and for vindicating and clearing of the doctrine of the said church from false aspersions and interpretations." The measure was at length passed as an ordinance by the authority of parliament. From the commencement, indications of the growing power of the Independents is perceptible in the cautious jealousy of the parliament, which required the assembly to inquire and report to the legislature, instead of conferring on it independent powers. The Assembly nominally sat for five years; but for some time before it was extinguished by Cromwell, it lost the confidence and co-operation of parliament. It consisted of 121 clergymen and certain lay assessors. From that peculiar union with Scotland manifested in the adoption of the Scottish Covenant as the Solemn League and Covenant of the two nations, some Scottish members were admitted as representatives of the General Assembly, and exercised a predominant influence on the deliberations. Of the documents adopted by them, one, the Directory of Worship, received the nominal assent of the English parliament. The Confession of Faith was received with some modifications. Both these documents, however, along with the Larger and Shorter Catechisms, were received into the Church of Scotland, and have since remained unaltered, as "agreed upon by the Assembly of Divines at Westminster, with the assistance of commissioners from the Church of Scotland, as a part of the covenanted uniformity in religion betwixt the churches of Christ in the kingdoms of Scotland, England, and Ireland." (J. H. B.)

ASSEN, a town of the Netherlands, capital of the province of Drenthe, containing 2800 inhabitants. It is 16 miles south of Groningen, and is connected with the Zuyder-Zee by the Smilder canal. It has a considerable trade in corn.

ASSENEDE, a town of Belgium, province of East Flanders, 12 miles N.N.E. of Ghent. It has some woollen and cotton manufactures, soap-works, &c. Pop. in 1851, 4131.

ASSENHEIM, a jurisdiction belonging to the Counts of Solms Rödelheim and Assenheim, now mediatized to the Grand Duchy of Hesse-Darmstadt. It is in the province of Upper Hesse. Its chief town, of the same name, is situated at the confluence of the Wetter and the Nidda. Pop. 800.

ASSENS, a seaport town of Denmark, situated upon the Little Belt, a strait of the Baltic which separates the isle of Fuhnen from the continent. It is the ordinary port for the traffic between the duchy of Sleswick and Fuhnen. Pop. 2700. Long. 9. 55. E. Lat. 55. 15. N.

ASSER, John, or Asserius Menevensis (*Asser of St David's*), was born in Pembrokeshire in South Wales, and educated in the monastery of St David's by the Archbishop Asserius, who, according to Leland, was his kinsman. In this monastery he became a monk, and by his assiduous application soon acquired universal fame as a person of profound learning and great abilities. King Alfred, the munificent patron of genius, about the year 880 sent for him to court and made him his preceptor and companion. As a reward for his services, he appointed him abbot of two or three different monasteries; and at last promoted him to the episcopal see of Sherburn, where he died and was buried in the year 910. He was, says Pitts, a man of happy genius, wonderful modesty, extensive learning, and great integrity of life. He is said to have been principally instrumental in persuading the king to restore the university of Oxford to its pristine dignity and lustre. He wrote the life of Alfred (*De Vita et Rebus Gestis Alfredi*), first published by Archbishop Parker in the old Saxon character, at the end of Walsingham's *Hist.* Lond. 1574. It was reprinted at Frankfort in 1603, in folio, and in 8vo at Oxford in 1722. Various other works are ascribed to Asser by Pitts and Leland.

ASSESSOR, among the Romans, was a term generally applied to a trained lawyer who sat beside a governor of a province or other magistrate, to instruct him in the administration of the laws. The system is still exemplified in Scotland, where it is usual in the larger towns for municipal magistrates in the administration of their civil jurisdiction to have the aid of professional assessors. In municipal corporations in England, officers with the same name are appointed to assist at the election of councillors and ascertain the result.

ASSETS, a technical English law word, derived through the old Norman phraseology from the same source as the French *assez*, enough. Assets are real or personal. Where a man hath lands in fee-simple, and dies seised thereof, the lands which come to his heirs are assets real; and where he dies possessed of any personal estate, the goods which come to the executors are assets personal.

ASSIDEANS, or Chasidæans (from the Hebrew *chasidim*, merciful, pious), those Jews who resorted to Mattathias the father of the Maccabees, to fight for the law of God and the liberties of their country. After the return of the Jews from the Babylonish captivity, there were two sorts of men in their church,—those who contented themselves with that obedience only which was prescribed by the law of Moses, and who were called *Zadikim*, i.e., the *righteous*,—and those who, over and above the law, superadded the constitutions and traditions of the elders, and other rigorous observances: these latter were called *Chasidim*, i.e., the *pious*. From the former sprung the Samaritans, Sadducees, and Caraites; from the latter the Pharisees and the Essenes. See 1st Macc. ii. vii.; 2d Macc. xiv. The name of Chasidim has also been assumed by a Jewish sect which originated in Poland about a century ago, and still exists.

ASSIDUI, or Locupletes, *i.e.*, tribute-payers, Roman citizens of the upper and wealthier classes, so designated by Servius Tullius, in contradistinction to the *Proletarii*, or those who benefit the state only by their progeny (*proles*). Cicero says, "*locupletes assiduos appellasset ab ære dando.*" —*Repub.* ii. 22.

ASSIGNAT, the name given to a peculiar species of paper money issued during the first French revolution. The influence of the system, operating along with the other attempts to regulate trade, form a prominent feature in the calamitous history of the epoch. The share borne in it by the assignats is at the same time a memorable instance, for the use of the economist and financier, of the hopelessness of projects for creating or preserving national wealth by an issue of paper money, not the representative of available wealth and real business transactions. The first issue of assignats was made in the security of the forfeited ecclesiastical property, and was adopted as a preferable alternative to throwing the forfeited lands on the market, which it was no doubt judiciously believed that so large an amount of property would glut. The holder of the assignats might use them as money, or claim the land which they represented. As more forfeitures occurred, the issue of assignats was increased. But it soon ceased to be measured by property, and was enlarged according to the exigencies of the revolutionary government. The paper money fell to half, then to a sixth part of the value of the same denomination in silver, and sinking rapidly through successive grades of decrease, silver held at last the value of 150 times its denomination in paper. In August of 1773, 3776 millions of francs were thus put in circulation: and virtually the assignats became worthless. The establishment of the maximum, and the other tyrannical interferences with trade by which revolutionary governments endeavour to support credit, have their proper place, along with the account of the condition of the country during the depreciation of the assignats, under the head of France. (J. H. B.)

ASSIGNMENT, Assignation, Assignee, are terms which, as conjugates of the verb assign, are of frequent technical use in the law of the different parts of the United Kingdom. To assign is to make over, and the term is generally used to express a transference by writing, in contradistinction to a transference by actual delivery. In England the usual expression is assignment, in Scotland it is assignation. The person making over is called *assignerer*, *assigner*, or *cedent*; the recipient, *assignee*. This last term is of important application in the law of bankruptcy in England and Ireland, as expressing persons of two classes, the official assignees and the trade assignees, to whom the realization and distribution of the bankrupt estate is committed. See Bankruptcy. (J. H. B.)

ASSIMILATION, in *Physics*, is that action or process by which bodies convert other bodies into their own substance and nature.

ASSINIE, a country of Upper Guinea, in Africa, at the western extremity of the Gold Coast. On the river of the same name, the French in 1843 established a factory.

ASSISI, a city in the delegation of Perugia, in the papal territory of Italy. It contains about 5000 inhabitants, depending chiefly for subsistence on the devotees, who, to the number of many thousands, make annual pilgrimages to the cathedral. This cathedral contains the tomb of St Francis, the founder of the Franciscan order. The poet Metastasio was born here in 1698. Long. 12. 24. 50. E. Lat. 43. 4. 22. N.

ASSITHMENT, a wiregeld, or composition, by a pecuniary mulct; from the preposition *ad*, and the Sax. *sithe*, *vice; quod vice supplicii ad expiandum delictum solvitur.*

ASSIZE, in old English law-books, is defined to be an assembly of knights and other substantial men, together with a justice, in a certain place and at a certain time; but the word, in its present acceptation, implies a court, place, or time, when and where processes, whether civil or criminal, are decided by judge and jury. In Scotland the word assize is still technically used to denote the fifteen persons who, deciding on criminal charges, are colloquially termed the jury.

ASSOCIATION (from the Latin *associare*, to join in fellowship), the act of associating or constituting a society or partnership, in order to carry on some scheme or business with more advantage. See Societies. On the influence of association as a political engine, see Agitation. For associations of workmen and employers, see Commandite.

Association of Ideas. See Metaphysics.

ASSOILZIE, in *Law*, to absolve by sentence of court.

ASSONANCE, in *Rhetoric* and *Poetry*, a term used where the words of a phrase or a verse have the same sound

or termination, and yet make no proper rhyme. These are usually accounted vicious in English. *Assonant Rhymes* are common among the Spaniards; thus *ligera, cubierta, tierra, mesa,* answer each other in a kind of *assonant* rhyme, having each an *e* in the penult syllable, and an *a* in the last.

ASSUAY, the most southern department of Ecuador, in South America. Cuença, Loxa, Jaca, and Borga, are its principal towns. Its chief productions are cinchona bark and silver.

ASSUMPSIT, in the *Law of England*, a voluntary promise, whereby a person assumes or takes upon him to perform or pay anything to another.

ASSUMPTION, a festival of the Romish church, in honour of the miraculous ascent of the Virgin Mary into heaven. The Greek church also observes this festival, and celebrates it on the 15th of August with great ceremony.

ASSUMPTION, in *Logic*, is the minor or second proposition in a categorical syllogism.

ASSUMPTION, *Deed of*. See SCOTS LAW.

ASSUMPTION, or ASSONGONG, one of the Marianne or Ladrone Islands in the Pacific Ocean, of a conical figure, dreary aspect, and almost totally covered with lava from the eruptions of a volcano in the centre. It has no anchorage near the shore. Long. 145. 55. E. Lat. 19. 45. N.

ASSUMPTION, the capital of the province of Paraguay in South America. It is situated on an obtuse angle formed by the eastern bank of the river Paraguay, 18 miles above the junction of the first mouth of the Pilcomayo, and 48 above that of the second. It was originally a small fort, but, from the convenience of its situation, in a few years it became a city, and in 1547 was erected into a bishopric. The adjacent territory is rich and fertile in a high degree, and abounds in a great variety of fruits. The air is temperate and the climate salubrious; the trees are perpetually green, and the rich pastures in the neighbourhood feed numerous flocks of cattle. The city is inhabited by Spaniards, Indians, and Mestizoes, who trade in hides, tobacco, and sugar. The Paraguay affords a channel of communication with Buenos Ayres; but the passage is long, owing to the rapid flow of the waters of that river: this, however, is considerably obviated by the favourable winds which blow from the south for a great part of the year. Pop. 12,000. Long. 57. 37. W. Lat. 25. 16. S.

ASSUMPTIVE ARMS, in *Heraldry*, are such as a person has a right to assume with the approbation of his sovereign and of the heralds.

ASSURANCE, or INSURANCE. See INSURANCE.

ASSUS, afterwards *Apollonia* (Pliny, v. 32), an ancient city of Mysia, on the Gulf of Adramyttium, was the birthplace of Cleanthes the Stoic, and for some time the residence of Aristotle. Its ruins are contiguous to the modern village of Beiram, 35 miles W.S.W. of Mount Ida; and the whole is said by Colonel Leake to give, perhaps, the most perfect idea of a Greek city that anywhere exists.—Leake's *Asia Minor*, p. 128; Fellows's *Asia Minor*, p. 46.

ASSYE, in Southern India, a village in the native state of Hyderabad, or dominions of the Nizam, situate on the tongue of land inclosed between the rivers Juah and Kaitna. This place is rendered famous in Indian history, by a decisive victory gained on the 23d September 1803, over the combined armies of Scindia and the Rajah of Berar, by Colonel Wellesley, afterwards Duke of Wellington. The British troops engaged in this battle amounted only to 4500 men, while those of the enemy consisted of nearly 50,000. The great disparity of numbers between the combatants, the skill and promptitude displayed by the British commander, combined with the valour of his men, and the signal defeat of the Mahrattas, all conspired to give a lustre to this action, which is scarcely surpassed by that of any other exploit in the annals of Indian warfare. Distance from Hyderabad, north-west, 261 miles. Lat. 20. 18. Long. 75. 55. (E. T.)

ASSYN-KALESSI, a village of Asia Minor, in Caria, occupying a peninsula among the branches of Mount Grius, with a mean but extensive fortress on the summit of the rock. This village stands on the site of the ancient Iasus, a considerable city, and many antiquities are still to be seen in it. Some of the most spacious sepulchres are at present inhabited by Greek families as their ordinary dwellings. Long. 27. 38. E. Lat. 37. 17. N.

ASSYRIA, the name of a country and empire of Asia, the capital of which was Nineveh. The boundaries of the country have been variously given by Greek and Roman historians. In its strictest and most original sense, it was applied to a long narrow district lying on the east side of the Tigris, and which is commonly called Assyria Proper. In a more extended sense, it comprehended the whole country watered by the Euphrates and Tigris, between the mountains of Armenia on the north, those of Kurdistan on the east, and the Arabian desert on the west; thus including not only Assyria Proper, but also Mesopotamia and Babylonia. It was also applied to the empire, the boundaries and extent of which varied with the character of its monarchs. Boundaries.

Assyria Proper was bounded on the north by Armenia, on the west and south-west by the Tigris, which separated it from Mesopotamia and Babylonia, on the south-east by Susiana, and on the east by the Zagros chain, separating it from Media. It corresponded to the modern pashalic of Mosul, including the plains below the Kurdistan and Persian mountains.

The upper part of this region is rugged and mountainous; while to the south and south-west extend vast level plains, interspersed with low ridges of hills of sandstone, limestone, and gypsum. According to Mr Ainsworth,—"Assyria, including Taurus, is distinguished into three districts; by its *structure*, into a district of plutonic and metamorphic rocks, a district of sedimentary formations, and a district of alluvial deposits; by *configuration*, into a district of mountains, a district of stony and sandy plains, and a district of low watery plains; by *natural productions*, into a country of forests and fruit trees, of olives, wine, corn, and pasturage, or of barren rocks; a country of mulberry, cotton, maize, tobacco, or of barren clay, sand, pebbly or rocky plains; and into a country of date trees, rice, and pasturage, or a land of saline plants." In the mountainous parts, iron, silver, copper, lead, and antimony, are found, and in the hills to the south-west are deposits of bitumen, naphtha, sulphur, and salt. Among the forest trees, pines, oaks, and ashes are common, as are also the walnut, mulberry, and plane; the last of which attains a great size. Besides the productions above enumerated, it yields gall-nuts, gum-arabic, mastich, manna, madder, castor-oil, and various kinds of grain, pulse, and fruit. In the mountain district, are bears (black and brown), panthers, lynxes, wolves, foxes, marmots, dormice, fallow and red deer, roebucks, antelopes, goats, &c.; and in the plains are found lions, tigers, hyænas, beavers, jerboas, wild boars, camels, &c. Bees are plentiful, producing honey of the finest quality. Natural Features. Products.

The two principal rivers which water this country, besides the Tigris, are its tributaries, the Great and Little Zab, both rising in the lofty mountains of Northern Kurdistan. The Great Zab rises in the elevated plateau between Lakes Van and Urumiyah, 7000 feet above the sea, and falls into the Tigris, after a winding course of 200 miles. The lesser Zab has several sources, the principal of which are about 20 miles south of Lake Urumiyah, and has a course of about 100 miles. The rivers Great and Little Zab divide this territory into three parts; that north of the Great Zab, called Aturia, was the most ancient seat of the monarchy, and contained Nineveh the capital; the part between the two Zabs was called Adiabene, and the part south-east of Rivers.

Assyria. the Little Zab contained the provinces of Apolloniatis and Sittacene. According to Ptolemy, Assyria was divided into six provinces, the most northern of which was Arrapachitis; south of it Calakine; then Adiabene, with Arbelitis to the north-east; while to the south lay Apolloniatis and Sittacene, mentioned above.

History. The labours of Messrs Layard, Rawlinson, Botta, and others, promise to throw much light upon the history and manners of the ancient inhabitants of this country. We shall, however, defer notice of their researches till we come to the article NINEVEH, in the expectation that, by that time, much additional light will be thrown upon this interesting subject, and shall, in the meantime, only give a short historical notice of the empire, founded principally on the sacred narrative; as, indeed, the accounts given by profane writers are so contradictory, and so mixed up with fables, that very little reliance can be placed upon them.

Being in the vicinity of Ararat, this district was early peopled after the Flood. From the word Asshur being used in Hebrew both as the name of Shem's second son, and for the country of Assyria, ambiguity has arisen as to the founder of this empire. In Genesis x. 11, the sacred historian, in speaking of Nimrod and his kingdom, adds—"Out of that land went forth Asshur, and builded Nineveh," or it may be translated as in the margin, "Out of that land he (*i.e.* Nimrod) went out into Assyria, and builded Nineveh." For reasons which it would be foreign to our present purpose to narrate, the latter reading is generally considered to be the more correct, and Nimrod is regarded as the founder of the Assyrian empire. For several centuries after this, Scripture is silent respecting the history of this country. In the days of Abraham, Chedorlaomer, a king of Elam, is mentioned (Gen. xiv.) as having, along with three other kings, invaded the territory of five petty princes of Palestine. These four kings, according to Josephus, were only commanders in the army of the Assyrian king, who had their dominion over Asia. In the time of the Judges, the Israelites became subject to a king of Mesopotamia, Chusan-rishathaim, who is by Josephus styled King of the Assyrians.

According to the Greek historians, the founder of the Assyrian empire was Ninus, who is represented as having conquered Babylon, Media, Egypt, and other countries. He was succeeded by his widow Semiramis, who must not, however, be confounded with another queen of that name who reigned some centuries later. She was succeeded, after a long and glorious reign, by her son, Ninyas, who, however, preferred luxurious ease and indulgence to martial glory. His example was followed by a long line of successors. In the reign of Teutames, one of these, the Trojan war broke out. Troy was then, according to Ctesias and other Greek writers, subject to the king of Assyria. This, however, seems very doubtful, as neither Homer nor Herodotus make any allusion to it. Of this degenerate race, Sardanapalus, the last of the dynasty, was the most effeminate and voluptuous. His feeble administration prompted Arbaces, the governor of Media, to revolt, a measure in which he was encouraged by the advice and assistance of Belesys, a Chaldean priest, who persuaded the Babylonians also to assert their independence. These provinces, aided by the Persians and other allies, attacked the Assyrians, defeated their army, and took the capital after a siege of two years. The king, to prevent his falling into the hands of his enemies, collected all his treasures, his wives, and concubines, within the palace, which he then set on fire, and thus perished.

After the death of Sardanapalus, the Assyrian empire was divided into three kingdoms, namely, the Median, Assyrian, and Babylonian. Arbaces retained the supreme power in Media, and nominated governors in Assyria and Babylon, who were honoured with the title of *kings*, while they remained subject and tributary to the Median monarchs.

The first king of Assyria alluded to in Scripture is he who reigned at Nineveh when the prophet Jonah was sent thither. Hales supposes him to have been the father of Pul, the first Assyrian monarch whose name is mentioned in Scripture, and dates the commencement of his reign B.C. 821. By that time the metropolis of the empire had become a magnificent and populous city; but one pre-eminent in wickedness. Pul invaded the land of Israel during the reign of Menahem, and obliged that king to purchase peace at the price of 1000 talents of silver (2 Kings xv. 19, 20). According to Newton, this event took place in the year 770 B.C. Hales agrees with Newton in supposing that at Pul's death his dominions were divided between his two sons, Tiglath-pileser and Nabonassar,—the latter ruling at Bablyon, and giving name to the "era of Nabonassar," which took its rise in his reign, B.C. 747. In the sixth year of the reign of Tiglath-pileser, Rezin king of Syria, and Pekah king of Israel, came up against Ahaz, and besieged him in Jerusalem. Ahaz thereupon sent messengers, with a large present to Tiglath-pileser king of Assyria, requesting his assistance. The Assyrian king accordingly invaded the territories of the confederate kings, annexed a portion of them to his own dominions, and carried captive a number of their subjects. In the year B.C. 729, he was succeeded by Shalman, Shalmaneser, or Enemessar. He made Hoshea, king of Israel, his tributary vassal, but finding him secretly negotiating with So or Sobaco, king of Egypt, he laid siege to the Israelitish capital, Samaria, and took it after an investment of three years (B.C. 719). He then reduced the country of the ten tribes to a province of his empire, carried into captivity the king and people, and settled Cuthæans from Babylonia in their room. Hezekiah, king of Judah, seems to have been for some time his vassal. We learn from Josephus, on the authority of the Tyrian annals, that he subdued the whole of Phœnicia with the exception of Tyre, which successfully resisted a siege of five years, and was at length relieved by his death in B.C. 715. Sargon, mentioned in Isaiah (xx. 1) as being king of Assyria, in whose reign Tartan, elsewhere mentioned as a general of Sennacherib, besieged and took Ashdod in Philistia, is by some supposed to be Shalmaneser or Esarhaddon, Sennacherib's successor; but Gesenius is probably more correct in thinking that he was a king of Assyria who succeeded Shalmaneser, and reigned only for two or three years.

The result of Tartan's expedition against Egypt and Ethiopia was predicted by Isaiah, while that general was yet on the Egyptian frontier at Ashdod. In the reign of Sennacherib, Hezekiah king of Judah threw off the Assyrian yoke, and allied himself with Egypt. This brought against him Sennacherib with a mighty host, who attacked and subdued the fenced cities of Judah, and compelled him to purchase peace with 300 talents of silver and 30 talents of gold. But notwithstanding this agreement, the king of Assyria was not long in returning to invest Jerusalem. By the divine interposition, however, a pestilence destroyed in one night the Assyrian army. Sennacherib himself fled to Nineveh, where he was slain by his sons, Adrammelech and Sharezer, about B.C. 709. The parricides fled to Armenia, and a third son, Esarhaddon, the Sacherdon or Sarchedon of Tobit, and the Asaradinus of Ptolemy's canon, ascended the throne. The earlier part of his reign seems to have been employed in subduing the provinces that had revolted against him. He settled colonists in Samaria; and it seems to have been in his reign that the captains of the Assyrian host invaded Judah, and carried Manasseh the king captive to Babylon, which appears to have been at that time the capital of the Assyrian empire. The subsequent history of the empire is involved in much obscurity. The Medes had already shaken off the yoke, and the Chaldeans soon appear on the scene as the dominant nation of Western Asia; yet Assyria, though

much reduced in extent, existed as an independent state for a considerable period after Esarhaddon. Hales, following Syncellus, gives as his successor a prince called Ninus (B.C. 667), who was succeeded (B.C. 658), by Nebuchodonosor, for the transactions of whose reign Hales relies on the apocryphal book of Judith, the authority of which, however, is very questionable. The last monarch was Saruc, (called also Sardanapalus,) in whose reign Cyaxares king of Media, and Nabopolassar viceroy of Babylon, besieged and took Nineveh, (B.C. 606). What remained of the empire was divided between the two victorious powers, and Assyria Proper became a province of Media.

Modern Assyria. The greater part of the country which formed Assyria Proper is now under the nominal sway of the Turks, who compose a considerable proportion of the population of the towns and larger villages, filling nearly all public offices, and differing in nothing from other Osmanlis. The pasha of Mosul is nominated by the Porte, but is subject to the pasha of Baghdad; there is also a pasha at Solymaneah and Akra; a bey at Arbil, a mussellim at Kirkook, &c. But the aboriginal inhabitants of the country, and of the whole mountain-tract that here divides Turkey from Persia, are the *Kurds*, the Carduchii of the Greeks; from them a chain of these mountains was anciently called the Carduchian or Gordyæan, and from them the country is now designated Kurdistan. Klaproth, in his *Asia Polyglotta*, derives the name from the Persian root *kurd*, *i. e.* strong, brave. They are still, as of old, a barbarous and warlike race, occasionally yielding a formal allegiance, on the west, to the Turks, and, on the east, to the Persians, but never wholly subdued; indeed, some of the more powerful tribes, such as the Hakkary, have maintained an entire independence. Some of them are stationary in villages, while others roam far and wide, beyond the limits of their own country, as nomadic shepherds; but they are all more or less addicted to predatory habits, and are regarded with great dread by their more peaceful neighbours. They profess the faith of Islam, and are of the Soonee sect. See NINEVEH.

ASTABAT, a small town of Persian Armenia, near the river Aras, 20 miles south-east of Nakschivan. The neighbouring country is fertile, and produces good wine. There is a root peculiar to this country, called *ronas*, used for dyeing red, great quantities of which are exported to India. Long. 46. 30. E. Lat. 39. N.

ASTAFFORT, a town of France, capital of a canton in the department of Lot and Garonne, arrondissement of Agen. Pop. 1318.

ASTELL, MARY, an English authoress, born at Newcastle-upon-Tyne in 1668. She was instructed by her uncle, a clergyman, in Latin and French, logic, mathematics, and natural philosophy. Having spent 20 years of her life in Newcastle, she went to London, where she continued her studies; and, deeply affected with the general ignorance of her sex, she published in 1697 a work entitled *A Serious Proposal to the Ladies, wherein a Method is offered for the Improvement of their Minds.* Her most finished performance was, *The Christian Religion, as professed by a Daughter of the Church of England*, published in 1705. She died in 1731.

ASTELL'S ISLAND, one of the English Company's islands, at the north-west part of the Gulf of Carpentaria, of moderate height, and wooded. Iron ore is found here. Lat. 11. 55. S.

ASTEROIDS (from ἀστήρ and εἶδος), a name given by Herschel to the new planets discovered between the orbits of Mars and Jupiter.

ASTERISK, a mark in form of a star (*), placed over a word or sentence, to refer the reader to the margin, or elsewhere, for a quotation, explanation, or the like.

ASTERISM, any small cluster of stars.

A-STERN, a sea phrase, used to signify anything at some distance behind the ship; being the opposite of A-HEAD, which signifies the space before her.

ASTI, a province of the duchy of Piedmont, in the continental dominions of the king of Sardinia. It is bounded on the north-east and east by Alessandria, on the south-east by Aqui, on the south-west by Alba, and on the west and north-west by Turin. It extends over 268 geographical square miles. It is a gently undulating plain, watered by the Tanaro and the Po; fruitful in all the productions of Italy, especially in corn, wine, and silk. Pop. in 1848, 136,065. Asti, (the ancient *Asta*) the capital of the province, is a large and well-built town, on the left bank of the Tanaro. It is the see of a bishop; and has a cathedral, a college, many churches and monastical institutions, with 24,000 inhabitants, who carry on a considerable trade in corn, wine, and silk, which is not a little promoted by the situation of the town on the high road from Alessandria to Turin and Coni. In the middle ages Asti was a great commercial city. Alfieri the poet was born here.

ASTLE, THOMAS, a well-known antiquary, was born in Staffordshire in 1734. His reputation, from his papers in the *Archæologia*, procured him in 1770 the parliamentary appointment of superintendent of the printing of the ancient records of the kingdom, which occupied him till 1775; when he was made keeper of the records in the Tower. His principal work is the essay on *The Origin and Progress of Writing*, published in 1784. He died 1st Dec. 1803.

ASTOMOUS (α and στόμα, *i. e., without a mouth*), a term used in zoology and in botany.

ASTORGA, a city of Spain, in the province of Leon, on a plain near the River Tuerto, and having the appellation of a marquisate, which title it confers on a noble family. It is surrounded with ancient fortifications, and has near it a castle in ruins. It has a cathedral, being the see of a bishop under the church of Compostella; and was called "the city of priests," from the great numbers of that profession formerly resident within its walls. Pop. 4000. Long. 6. 9. 53. W. Lat. 42. 27. 9. N.

ASTORIA, a settlement in the territory of Oregon, about 12 miles from the mouth of the Columbia River, named after Mr Astor, its founder, who had designed it for an extensive fur depôt. In 1813 it was taken possession of, in the name of Great Britain, by Captain Black of the Raccoon, who changed its name to Fort George; but at the close of the war it was restored to the United States. It now consists of only a few log-houses. It possesses a good harbour, which is chiefly used by the shipping of the North West Company, to whom Mr Astor sold the property.

ASTRABAD, or ASTERABAD, a small province of Persia, bounded on the north by the Caspian Sea and the desert, on the south by the Elburz Mountains, west by Mazanderan, and east by the River Gourgan. The country, although mountainous, and interspersed with deep forests, in which it is scarcely possible to travel, possesses beautiful and fertile valleys, producing rice, wheat, and other grains in abundance, or spread out in a boundless expanse of verdure, the pasturage of numerous flocks and herds. Fraser, who travelled through Persia in 1822, extols in the most lavish terms the appearance of the country. The soil, with little culture, is exceedingly productive, owing to the abundance of water which irrigates and fertilizes it. But while the province in many parts presents a landscape of luxuriant beauty, it is a prey to the ravages of disease, and the frequent incursions of the surrounding tribes. The heavy torrents which fall in the rainy season stagnate in the forests, forming morasses which, in the heats of summer and autumn, exhale a pestilential vapour, from the decomposition of the vegetable matter they contain. From these seats of noxious effluvia the wandering tribes of shepherds fly beyond the Gourgan or the Attruck, and live on the verge of the burn-

ing sand, although they have to carry water for each day's consumption from the distant river. The better classes retire from the intense heats of summer into the mountains; but the settled inhabitants of the villages, who cannot so easily remove, and who generally remain, suffer severely from sickness. The inhabitants, notwithstanding the unhealthiness of their climate, are a stout and athletic race. The revenue derived from this province by the king of Persia does not exceed the value of L.7000 sterling. It is famous, however, for furnishing a supply of matchlocks for the king's body-guard. This is the ancient Hyrcania, and is the native country of the Kadgers, a Turkish tribe, of whom the king is the head, and on whom he considers he can rely in times of danger.

Astrabad, or Asterabad, a town of Persia, the capital of the above province, is situated near the mouth of the River Gourgan, which flows into the Caspian, and at the head of a sheltered bay, extremely convenient for shipping. Astrabad is a pleasant, well-built town, about 3½ miles in circuit, and highly picturesque in appearance, from the buildings being intermingled with trees and extensive gardens. It was formerly larger, but Nadir Shah contracted it within its present limits. A mound of earth surrounds it, the remains of a mud wall once lofty and formidable, and defended by numerous towers, and also by a wide and deep ditch, now almost filled with rubbish. Astrabad owes its origin to Yezzen-ibn-Messlub, an Arab chief of great celebrity, who commanded the armies of Soliman, the seventh khalif of the Ommiades, about the beginning of the seventh century. It was destroyed by Tamerlane. In 1744 Hanway visited this place, and attempted to open a direct trade with it from Europe. It has now but little trade; and the bazaars, though extensive, are but poorly filled, containing little more than the necessary supplies for the consumption of the place. The number of houses within the walls is estimated at from 2000 to 3000. The town is extremely unhealthy during the hot weather, owing to the noxious exhalations of the surrounding forests. Distance N.E. of Ispahan 400 miles. Long. 54. 25. E. Lat. 36. 50. N.

ASTRAKAN, a government of European Russia, bounded on the south-east by the Caspian Sea, north-east by Orenburg, north by Saratov, west by the country of the Don Cossacks, and south-east by the Caucasus. It lies between Lat. 44. 50. and 49. 50. N. and between Long. 43. 30. and 51. 0. E. It has an area of about 50,000 square miles, divided into two nearly equal parts by the Volga, and consists chiefly of sandy deserts, interspersed with saline lakes; but in the delta and on the banks of the rivers, grapes and other fruits of southern climates are raised. The population in 1846 was estimated at 284,400, comprising Russians, Tartars, Georgians, Armenians, Persians, Hindus, &c., who engage in the rearing of horses, cattle, and sheep, and also in the fishing of sturgeon, which forms the principal source of wealth to the government. The annual revenue derived from this source is estimated at from two to three million of rubles. The vicissitudes of climate are great: with a mean annual temperature of 48° Fahr., the summer averages 70°, and the winter 13° Fahr.

Astrakan, the capital of the government of the same name, is situated on a small island in the Volga, about 30 miles above the influx of that river into the Caspian. It consists of three parts, 1. the *Kremlin* or citadel, which stands on a hill, and contains the cathedral, a spacious brick edifice with the archbishop's palace and the convent of the Trinity; 2. the *Belogorod* or white town, containing the government buildings, bazaars, &c.; 3. the *Llobodeo* or suburbs, where the bulk of the population reside. In the last the streets are narrow, irregular, and mostly unpaved, and the houses are built of wood. It is the seat of a Greek and of an Armenian archbishop, also of an admiralty board; and it contains a number of Greek and Armenian churches and convents, a catholic and a Lutheran church, a Hindu temple, several mosques, a botanic garden, three bazaars, a gymnasium, an ecclesiastical seminary, and several inferior schools. From its favourable position, it enjoys a very considerable trade both with the interior of Russia, and with India, Persia, &c. Besides its importance as a fishing station, it has considerable manufactures of cotton, silk, leather, &c. Lat. 46. 21. N. Long. 47. 55. E. Pop. in 1848 estimated at 50,000.

This city was anciently the capital of a kingdom belonging to the Tartars, who were expelled in 1554 by the Russian prince Iwan Basilowitz. In 1569 it was besieged by the Turks, but they were defeated with great slaughter by the Russians. In 1670 it was seized by the rebel Stenko Razin; but he was soon dispossessed of it by his uncle Jacolof, who remained faithful to the Czar. In 1702 and 1718 it suffered severely from conflagrations; and in 1830 the cholera swept away a great portion of its inhabitants.

ASTRÆA, in *Astronomy*, a name which some give to the sign Virgo, by others called *Erigone*, and sometimes *Isis*. The poets feign that Justice quitted heaven to reside on earth in the golden age; but growing weary of the iniquities of mankind, she left the earth and returned to heaven, where she took her place among the stars, and from her orb still looks down on the ways of men.

ASTRAGALOMANCY, a species of divination performed by throwing small pieces, with marks corresponding to the letters of the alphabet, the accidental disposition of which formed the answer required. This kind of divination was practised in a temple of Hercules in Achaia. The word is derived from ἀστράγαλος, and μαντεία.

ASTRINGENTS, a class of medicines which are used for binding or contracting the several parts, external or internal, of the human system, for restraining profuse discharges, coagulating the fluids, condensing and strengthening the solids. The principal astringents are the mineral acids, alum, lime-water, chalk, several preparations of copper, zinc, iron, &c., catechu, kino, oak-bark, galls, and all vegetable substances containing tannin.

ASTROLABE, a stereographic projection of the sphere, either on the plane of the equator, the eye being supposed to be in the pole of the world; or upon the plane of the meridian, when the eye is supposed in the point of the intersection of the equinoctial and horizon.

Astrolabe is also the name of an instrument formerly used for taking the altitude of the sun or stars at sea.

Astrolabe, among the ancients, was the same as our armillary sphere.

ASTROLOGY (from ἀστρόν and λόγος), a pretended science, teaching to judge of the effects and influences of the stars, and to foretell future events by the situation and different aspects of the heavenly bodies.

This science was divided into two branches, *natural* and *judiciary*. To the former belonged the predicting of natural effects; as the changes of weather, winds, storms, hurricanes, thunder, floods, earthquakes, &c. Judiciary or judicial astrology is that which pretended to foretell moral events, as if they were directed by the stars. It is commonly said to have been invented in Chaldea, and thence transmitted to the Egyptians, Greeks, and Romans; though some will have it of Egyptian origin. At Rome the people were so infatuated with it, that the astrologers, or, as they were then called, the *mathematicians*, maintained their ground in spite of all the edicts of the emperors to expel them from the city. The same superstition has prevailed in modern nations. The French historians tell us, that in the time of Queen Catherine dè'Medici, astrology was so much in vogue that the most inconsiderable thing was not to be done without consulting the stars. And in the reigns of King Henry III. and IV. of France, the predictions of astrologers were the common theme of the court conversation.

ASTRONOMY.

ASTRONOMY, from αστηρ or αστρον, *a star*, and νομος, *a law*, is the science which treats of the laws observed by the stars in their motions. By an extension of signification, it embraces every thing that is known relating to the nature and constitution, as well as to the motions, of the celestial bodies.

The present treatise is divided into Four Parts. In the *First*, which contains the History of Astronomy, the progressive advancement of the science from the times of the Chaldeans and Egyptians to the present day is briefly sketched, and the labours of those illustrious individuals commemorated, who have either theoretically or practically contributed most to its progress. The *Second Part*, which we have denominated Theoretical Astronomy, is devoted to a general view of the science,—to the explanation of the different theories and methods by which the motions of the celestial bodies are represented, and their places computed; and the description of such facts as observation has made known respecting their nature and constitution. *Part Third* treats of Physical Astronomy; and *Part Fourth* of Practicai Astronomy.

PART I.

HISTORY OF ASTRONOMY.

Astronomy, if we dignify by that name the first rude attempts that were made to discover the order and connection of the celestial motions, may probably be regarded as the most ancient of all the sciences. In fact, a certain degree of attention to the heavenly bodies is forced even on the savage who inhabits the forest, and derives his subsistence from the spontaneous productions of the earth. The regular vicissitude of day and night inevitably compels him to observe the diurnal course of the sun; and he cannot fail soon to perceive, that the variety and succession of the seasons is equally dependent on the oblique annual course of the same great luminary. The moon, too, in the absence of the sun, is an object so conspicuous, so consoling, and so useful, that her motions must at all times have been watched with attention and interest; while her various phases, her alternate waxings and wanings, her regular disappearance and return after equal intervals of time, would be contemplated with admiration and delight. Nor are the wonders of the starry firmament less calculated to strike even the most heedless observer of the heavens. The magnificent spectacle of the sky bespangled with brilliant points, and revolving in obedience to eternal and unalterable laws, affords a constant succession of new objects of sublime and exalted contemplation. The occasional recurrence, also, of eclipses and other unusual phenomena, which seem to interrupt the general order and uniformity of the celestial motions, would stimulate to attentive observation; for the vanity of man has in all ages rendered him eager to connect his own destiny with the heavens, while his timidity has prompted him to regard every apparent deviation from the ordinary course of events as an emblem of the wrath, and a precursor of the vengeance, of superior beings.

But though mankind were probably first impelled by motives of mere curiosity to observe the courses of the stars, no great length of time could elapse ere they perceived that the regular and uniform revolutions of the heavens might be rendered subservient to their own wants and conveniencies. By the help of the stars the shepherd, during the night, could count the hours, the traveller track his course through the uniform wastes of the desert, and the mariner guide his bark over the ocean: the husbandman, also, learned to regulate his labours by the appearance of certain constellations, which gave him warning of the approaching seasons. The indications derived from the simple observation of such phenomena were doubtless extremely vague; but as civilisation advanced, the necessity of determining accurately the length of the solar year and of the lunar month, in order to regulate the calendar and the religious festivals, led to the accumulation and comparison of different observations, whereby errors were gradually diminished, and the foundations laid of a more perfect acquaintance with the heavenly motions.

Astronomy, presenting so many objects of interesting curiosity, and having so many practical uses, could not fail to be one of the sciences first cultivated by mankind. Its origin is consequently hid amidst the obscurity and traditions of the remotest ages, and is in fact coeval with the origin of society, and the earliest development of the human intellect. The records or traditions of almost every ancient nation furnish some traces of attention to the state of the heavens, and of some rude attempts to discover the laws, the order, and the period of the most remarkable phenomena,—such as eclipses of the sun and moon, the motions of the planets, and the heliacal risings of the principal stars and constellations. The Chaldeans and Egyptians, Chinese and Indians, Gauls and Peruvians, equally regard themselves as the inventors of astronomy; an honour, however, of which Josephus deprives them all, in order to ascribe it to the antediluvian patriarchs. The fables relating to the two columns of brick and marble which these sages are said to have erected, and on which they engraved the elements of their astronomy, to preserve them from the universal destruction by fire and water to which, they are said to have learned from Adam, the earth was doomed, are not worth the trouble of repetition; nor is there any better proof than the assertion of that credulous historian, of their acquaintance with the *annus magnus*, or, as is most probably supposed, the astronomical cycle of 600 years, which brings back the sun and moon to the same points of the heavens so nearly, that its discovery implies a pretty correct knowledge of the solar and lunar motions. Passing over, therefore, those periods that present us only with a scanty detail of traditional observations or unimportant facts, we will proceed to give a brief account of the state of astronomy among some early nations who have undoubtedly contributed to the improvement of the science, or who, at least, have transmitted to future ages some monuments of their

History.

astronomical labours, and of their attention to celestial observations.

Astronomy of the Chaldeans, Egyptians, Phœnicians, Chinese, and Indians.

Chaldeans.

According to the unanimous testimony of the Greek historians, the earliest traces of astronomical science are to be met with among the Chaldeans and Egyptians. The spacious level and unclouded horizon of Chaldea afforded the utmost facilities for observing the celestial phenomena; and its inhabitants, enjoying the leisure afforded by a pastoral life, and stimulated by the vain desire of obtaining a knowledge of the future from the aspects of the stars, assiduously cultivated astronomy and astrology. By a long series of observations of eclipses, extending, according to the testimony of some authors, over nineteen centuries, or even a longer period, they had discovered the cycle of 223 lunations, or eighteen solar years, which, by bringing back the moon to nearly the same position with respect to her nodes, her perigee, and the sun, brings back the eclipses in the same order. This is supposed to be the period which they distinguished by the name of *Saros*. They had others, to which they gave the names of *Sossos* and *Neros;* but nothing positive is known with regard to their nature or extent. One thing only is certain, which is, that these Chaldaic periods, whatever they were, were founded on no theoretical knowledge of the celestial motions. They were purely empirical, detected by the comparison of recorded observations, and suppose neither theory nor science, unless, indeed, a simple arithmetical operation is to be considered as such; nor is there any reason to suppose that the Chaldeans employed any process of computation whatever in their predictions of eclipses. Having once established their cycle, they were in possession of a simple means of predicting all those which occurred in the course of it, with as great a degree of accuracy as they considered requisite.

The knowledge of these lunisolar periods among the Chaldeans is doubtless of great antiquity. Simplicius, the commentator of Aristotle, asserts that Callisthenes transmitted to Aristotle from Babylon a collection of observations of all the eclipses which had happened during the nineteen centuries that preceded the conquest of Alexander. This relation, however, is at variance with the accounts given by other historians. Epigenes, cited by Seneca and Pliny, who is supposed to have lived shortly before the time of Alexander, mentions observations of 730 years that had been found preserved on columns of brick. Ptolemy also makes mention of certain observations of eclipses that had been brought from Babylon, several of which he had calculated and verified; but the earliest of these ascends only to the year 720 before our era, or to the 26th of Nabonassar; and if either Hipparchus or himself had been acquainted with others of a more ancient date, they would doubtless have employed them in the determination of the mean motion of the moon. From this circumstance it appears probable that the Chaldeans had no observation sufficiently exact to be of any use to astronomy prior to the time of Nabonassar.

According to Apollonius of Myndus, the Chaldeans supposed the comets to be substances of the same nature as the planets; that they are visible only during a portion of their revolutions, and that they re-appear after certain intervals. But this statement, which argues some just notions respecting the celestial bodies, is contradicted by Epigenes, who himself studied among the Chaldeans, and who affirms, that instead of regarding the comets as subjected like the planets to the operation of eternal laws, they attributed their formation to vortices of inflamed matter, supposing them to have only a temporary existence, and to move in random directions through the fields of space. Diodorus says, that they regarded the world as eternal and imperishable, and held that its order is due, not to chance, but to a divine providence; that the planets, which have peculiar motions, announce future events by their various aspects and colours; that they portend rains, tempests, excessive heats; sometimes also the appearance of comets, eclipses, earthquakes, and, in short, whatever has a beneficial or hurtful influence on the fortunes of nations or individuals.

History.

From the few facts that can be gleaned from the vague accounts given by ancient authors of the astronomy of the ancient Chaldeans, it may be inferred that their boasted science was confined to observations of the simplest and rudest kind, neither guided by theory, nor assisted by instruments; for, notwithstanding the assertion of Herodotus, it is doubtful if they were acquainted even with the gnomon, the simplest of all instruments for determining the obliquity of the ecliptic, the altitude of the pole, and the length of the tropical year. If to the knowledge of their lunisolar periods, the result of ages of observation, we add the notion of a spherical revolution about an inclined axis, and an idea of the principal circles of the sphere and the position of the poles, the sum will comprehend all that constituted the science of a people regarded by antiquity as having made the greatest progress in the science of the stars. Astronomy, however, owes some obligations to their humble labours. The observations which they recorded served to correct the theories that were afterwards imagined by the more brilliant genius of the Greeks, and thereby furnished some materials for the edifice of the world.

Egyptians

The Egyptians were in ancient times the rivals of the Chaldeans in the cultivation of astronomy; and although they have left behind them still fewer monuments of their labours, they have obtained, through the exaggerated statements of the Greeks, even a greater reputation. The Greeks acknowledge themselves indebted to the Egyptians for their science and civilisation; but regarding themselves likewise as descendants of that ancient people, they indulged their vain-glory in magnifying the accounts of the antiquity and knowledge of their supposed ancestors. It is not improbable that some traditional observations of the heavens, along with some arts indispensable to society even in its earliest stages, were carried into Europe by tribes migrating from the banks of the Nile; and it is certain that the early philosophers of Greece travelled into Egypt for the purpose of acquiring a more perfect knowledge of astronomy than could be obtained in their own country. But the facts from which it can be inferred that the Egyptians had much to communicate, are few and ill attested. They are also blended with so much absurdity and fable, that no accurate notions can be formed, from the accounts that have been transmitted to us, of the real advances which that people had made in astronomical science. The priests were the depositaries of the national knowledge; and they carefully concealed it from the vulgar by shrouding it in allegories, traces of which, it has been remarked, may be detected in the institutions even of the present day.

According to Diogenes Laertius, the Egyptians reckoned 48,853 years from Vulcan to Alexander, during which they had observed 373 eclipses of the sun, and 832 of the moon. These numbers in fact nearly express the relative proportion of the eclipses of the two luminaries; but the enormous length of the period altogether exceeds

History. the bounds of credibility; and it has been remarked that the same number of eclipses might have been observed within the more probable period of twelve or thirteen centuries. Supposing the numbers to be accurately stated, it will follow that, as the observations terminated with the conquest of Alexander, the Egyptians must have been in the habit of observing eclipses at least 1600 years before the commencement of our era. By attentively observing the heliacal rising of the star Sirius, to which they gave the name of Thaat, or Thoth (the Watch-Dog), because its appearance shortly preceded the overflow of the waters of the Nile, the Egyptians had discovered that the year consists of $365\frac{1}{4}$ days. This was their religious or sacred year. Their civil year consisted of only 365 days; consequently the sacrifices and feasts, which were regulated by it, successively corresponded to the different seasons. Instead of attempting to obviate this inconvenience by intercalation, they imposed an oath on their kings to maintain the use of the civil year, superstitiously imagining that each of the seasons would be blessed and rendered prosperous by enjoying in its turn the celebration of the feast of Isis. The difference between the lengths of the sacred and civil year suggested to them their famous sothic or canicular period of 1460 solar years, corresponding to 1461 civil years of 365 days, and which consequently brings back the months and festivals to the same seasons. Dion Cassius ascribes the week to the Egyptians, and says that they first dedicated a day to each of the planets; but it is sufficiently proved that this short cycle was in use among the Chinese and Indians from the remotest times, and was even known to the Druids of Gaul and Britain. It was more probably suggested to different nations by the phases of the moon. The Egyptians had likewise been attentive to the courses of the planets. Diodorus Siculus affirms that they could explain the phenomena of the stations and retrogradations; and Macrobius ascribes to them the knowledge of the real motions of Mercury and Venus, and says that they regarded these planets as satellites of the sun. This notion would do credit to their philosophy; but it is unfortunately not mentioned by any other author, and for this reason the testimony of Macrobius is suspected. The state of their practical astronomy may in some measure be inferred from the means they employed to determine the magnitude of the sun's apparent diameter. By comparing the time, observed by means of a clepsydra, which the sun takes to mount above the horizon at the equinox, with that in which he makes a complete revolution of the sky, they estimated his diameter at 28′ 48″. An observation of this kind is liable to great uncertainty; and as there is no evidence that the Egyptians possessed the slightest knowledge of spherical trigonometry, they would probably make no allowance for the obliquity of the equator to their horizon; and if this correction was left out of the calculation, as it probably was, their diameter, already too small, ought to have been still farther reduced, and to have amounted only to 24′ 42″. It has been conjectured by Goguet, that the obelisks of Egypt were intended to serve the purpose of gnomons; and this conjecture acquires some probability from their needle-shaped form, and the narrowness of their bases relatively to their heights. It has however been proved by MM. Jollois and Devilliers, in their description of Thebes, that the obelisks were connected with the walls of temples and palaces; a disposition which rendered them entirely unfit for the purposes of astronomical observation. Their summits were also of so unfavourable a form, that the Romans were obliged to surmount them with a ball in order to obtain a distinct and well-defined shadow. The pyramids have also been adduced as evidences of the early progress of astronomy among the Egyptians; for the faces of these stupendous masses are turned directly towards the four cardinal points, from which it is evident that the people by whom they were constructed were at least acquainted with the method of tracing a meridional line.

From this brief account it appears, that the only circumstances with which we are acquainted that imply the knowledge of astronomical methods among the Egyptians, are the length of the year, the doubtful discovery of the true motions of Mercury and Venus, and the position of the pyramids. The Chaldean observations were of use to Hipparchus and Ptolemy in the determination of some important elements; but those of the Egyptians exercised no influence whatever on the future progress of the science.

Phœnicians. The Phœnicians are also generally enumerated among the nations who cultivated astronomy at a very early period, though it does not appear, from any facts mentioned by ancient authors, that they addicted themselves to the observation of the heavens, or made any discoveries relative to the motions of the planets. That they excelled in the art of navigation is certain, from the commercial intercourse which they carried on with many places on the coasts of Africa and Spain, and in the principal islands of the Mediterranean; and it may readily be allowed that in their long voyages they would direct their course during the night by the circumpolar stars. If they had any speculative notions of astronomy, these were probably derived from the Chaldeans or Egyptians.

Chinese. In China, astronomy has been cultivated from the remotest ages, and always been considered as a science indispensably necessary to the civil government of the state. The Chinese boast of a series of eclipses, recorded in the annals of the nation, extending over a period of 3858 years, all of which, they pretend, were not only carefully observed, but calculated and figured previous to their occurrence. The same motives which led the Chaldeans and Egyptians to attend to the celestial phenomena, namely, the regulation and division of time, had equal influence among the Chinese; and we accordingly find the care of the calendar occupying the attention of their earliest princes. The emperor Fou-Hi, whose reign commenced about 2857 years before our era, is said to have assiduously studied the motions of the celestial bodies, and laboured to instruct his ignorant subjects in the mysteries of astronomy. But as they were yet in too rude a condition to be able to comprehend his theories, he was obliged to content himself with giving them a rule for the computation of time by means of the numbers 10 and 12, the combination of which produces the cycle of 60 years, which is the standard or unit from which they deduce their hours, days, and months. Tradition is silent with respect to the sources from which Fou-Hi derived his own knowledge. The Chinese attribute to him also the invention of arithmetic and music. In the year 2608 B. C., Hoang-Ti caused an observatory to be built, for the purpose of correcting the calendar, which had already fallen into great confusion, and appointed one set of astronomers to observe the course of the sun, another that of the moon, and a third that of the stars. It was then discovered that the twelve lunar months do not exactly correspond with a solar year; and that, in order to restore the coincidence, it was necessary to intercalate seven lunations in the space of nineteen years. If this fact rested on undoubted evidence, it would follow that the Chinese had anticipated the Greeks by 2000 years in the discovery of the Metonic cycle. The reign of Hoang-Ti is also rendered memorable by the institution of the *Mathematical Tribunal*, for promoting the science of

History.

astronomy, and regularly predicting eclipses, to which an extraordinary importance has always been attached in China. The members of this celebrated tribunal were made responsible with their lives for the accuracy of their predictions, by a law of the empire, which ordained that, " whether the instant of the occurrence of any celestial phenomenon was erroneously assigned, or the phenomenon itself not foreseen and predicted, either negligence should be punished with death." In the reign of Tchong-Kang, the two mathematicians of the empire, Ho and Hi, were the victims of this absurd and sanguinary law; an eclipse having taken place which their skill had not enabled them to foresee.

The emperor Yao, who mounted the throne, according to the Chinese annals, about the year 2317 B. C., gave a new impulse to the study of astronomy, which had begun already to decline. He ordered his astronomers to observe with the utmost care the motions of the sun and moon, of the planets and the stars, and to determine the exact length of each of the four seasons. He sent Hi-Tchong to the east to observe the star situated at the point of the vernal equinox, Hi-Tchou to the south to examine that at the summer solstice, Ho-Tchong to the west, and Ho-Tchou to the north, to observe those situated respectively at the autumnal equinox and winter solstice. These docile observers found stars in the positions assigned by the emperor; but the extraordinary resemblance of their names imparts a fabulous air to the whole relation, and excites a very excusable incredulity even with regard to those statements which involve no improbability. To this emperor are attributed the Chinese division of the zodiac into 28 constellations, called the houses of the moon, and the severe laws already noticed in regard to the erroneous prediction of the celestial phenomena.

From the time of Yao the Chinese year consisted of $365\frac{1}{4}$ days. They also divided the circle into $365\frac{1}{4}$ degrees, so that the sun daily described in his orbit an arc of one Chinese degree. Their common lunar year consisted of $364\frac{448}{940}$ days; and by combining this number with $365\frac{1}{4}$, they formed the period of 4617 years, after which the sun and moon again occupy the same relative positions.

The earliest Chinese observations we are acquainted with, sufficiently precise to afford any result useful to astronomy, were made by Tcheou-Kong, whose reign commenced about the year 1100 before our era. Two of these observations are meridional altitudes of the sun, observed with great care at the village of Loyang, at the time of the summer and winter solstices. The obliquity of the ecliptic thus determined at that remote epoch is $23° 54' 3{\cdot}15''$; a result which perfectly agrees with the theory of universal gravitation. Another observation, made about the same time, relates to the position of the winter solstice in the heavens; and it also corresponds to within a minute of a degree with the calculations of Laplace. Laplace considers this extraordinary conformity as an indubitable proof of the authenticity of those ancient observations.

The golden age of Chinese astronomy extended from the reign of Fou-Hi to the year 480 B. C.; that is, over a space of 2500 years. It is only, however, towards the latter part of this long period that the history of China becomes in any degree authentic; and the true date which must be assigned for the commencement of observations on which any reliance can be placed, is the year 722 B. C.; that is, 25 years posterior to the era of Nabonassar. From that period to the year 400 B C. Confucius reckons a series of 36 eclipses, and of these 31 have been verified by modern astronomers. After this the science fell into great neglect, notwithstanding the inveterate tenacity with which the Chinese in general adhere to their ancient customs. The decline of their astronomy is ascribed, whether justly or not, to the barbarous policy of the emperor Tsin-Chi-Hong-Ti, who, in the year 221 B. C., ordered all the books to be destroyed, excepting those only which related to agriculture, medicine, and astrology, the only sciences which he considered as being of any use to mankind. His fury, it is true, was principally directed against those of Confucius, the stern morality of which he felt to be a censure on his own profligacy; but those of science and astronomy were included in the general destruction. In this manner, it is said, the precious mass of astronomical observations and precepts which had been accumulating for ages was irretrievably lost.

Lieou-Pang, the successor of Tsin-Chi-Hong, endeavoured to repair the disaster, by re-establishing the tribunal of the mathematics, and ordering a new series of observations to be undertaken. About the year 104 B. C. the astronomer Sse-Ma-Tsien gave some precepts for the calculation of eclipses, the motions of the planets, and the syzygies. He employed instruments of copper, the nature and construction of which are however not very well understood, for measuring the extent of the 28 zodiacal constellations; and he observed the meridional altitudes of the sun, by means of a gnomon 8 feet high. The differences of right ascensions, and the intervals between the risings, settings, and culminations of the stars, were measured by clepsydræ. It would appear that after this period astronomical observations continued for some time to be made in China with considerable regularity. In the 164th year of our era the astronomer Tchang-Heng constructed armillary spheres and a celestial globe. He also formed a catalogue of stars, which is said to have contained 2500, but without either latitudes or longitudes; a circumstance which gives us a very unfavourable idea of the state of practical astronomy at that time. About the eighth century of our era, all knowledge of the science seems to have been again lost. The predictions were erroneous; and the Chinese witnessed, with superstitious terror, eclipses of which their astronomers had given them no intimation. This induced the emperor Hieng-Tsong to call to his court the astronomer Y-Hang, by whose indefatigable activity a reform was speedily effected. With a view to determine the situations of the principal places of the empire, this astronomer constructed gnomons, spheres, astrolabes, quadrants, and other instruments; and sent one company of mathematicians to the south, and another to the north, with directions to observe daily the altitudes of the sun and the polar star. The latitudes of the cities were determined by observing the shadow of the gnomon, and the longitudes by eclipses of the moon. Y-Hang had the mortification of announcing two eclipses which did not take place. On these occasions he alleged the usual excuse, namely, that his calculus was not in error, but that the celestial bodies had deviated from their ordinary courses out of respect to the virtues of the emperor. The fate of Ho and Hi had probably suggested to the Chinese astronomers this ingenious mode of disarming the emperor's resentment by flattering his vanity.

206 B.C.

On considering attentively the accounts which have been given of the Chinese astronomy, we find that it consisted only in the practice of observations which led to nothing more than the knowledge of a few isolated facts. The missionaries who were sent out by the Jesuits about the end of the seventeenth century, to whom we are indebted for what is known of the early history

History.

of China, either seduced by some appearances of truth, or thinking it prudent to conciliate the people whom they were attempting to convert, adopted their marvellous relations regarding the antiquity of their science, and spread them over Europe. As the history of the nation begins to become more authentic, their astronomy shrinks into its real but insignificant dimensions. Superstitiously attached to their ancient usages, and blindly adopting the habits of their ancestors, the Chinese continued to observe the heavens from century to century without making the slightest advances in theoretical knowledge. In later times they have adopted many improvements, for which they are entirely indebted to foreigners. During the time of the caliphs many Mahometans passed into China, carrying with them the astronomical methods and knowledge of the Arabians. The missionaries introduced the science of Europe; and the most that can be said in praise of the Chinese is, that their government sometimes relaxed so far its spirit of jealousy and exclusion, as to afford protection to these strangers, adopt their arts, and place them at the head of the mathematical tribunal.

Indians.

The astronomy of the Indians forms one of the most curious problems which the history of science presents to the consideration of the learned, and one which, notwithstanding the numerous dissertations to which it has given rise, still continues involved in great uncertainty. Of the science of the ancient nations, of which we have already spoken, the accounts which have come down to our times are founded on conjecture and tradition; for few monuments remain to confirm or confute the glowing descriptions which authors have given of its high antiquity and great perfection. But the claims of the Indians rest on more solid foundations. We are in possession of the tables from which they compute the eclipses and places of the planets, and of the methods by which they effect the computation: we have, in short, an Indian astronomy committed to writing, which represents the celestial phenomena with considerable exactness, and which, therefore, could only be produced by a people far advanced in science. But the difficulty of the problem consists in determining the sources from which this science originated, and the epoch of its existence; whether it was created by the people who now blindly follow its precepts without understanding its principles, or was communicated to them by another race of a bolder and more original genius, through channels with which we are unacquainted. Some authors regard India as the cradle of all the sciences, particularly of astronomy, which they suppose to have been cultivated there from the remotest ages; others date the origin of the Indian astronomy from the period when Pythagoras travelled into that country, and carried thither the arts and sciences of the Greeks; a third opinion is, that astronomy was conveyed to India by the Arabians in the ninth century of our era, and that the Brahmins are only entitled to the humble merit of adapting the rules and practices of that people to their own peculiar methods of calculation. We shall endeavour to describe very briefly the existing monuments of the Indian astronomy, which furnish the only data from which a rational conjecture can be formed relative to its antiquity and precision.

We possess four different sets of tables of Indian astronomy. The first which were known in Europe were brought from Siam by La Loubère, who had resided in that country as ambassador from Louis XIV. They were communicated by him to the celebrated Cassini, who, notwithstanding the difficulties arising from the complicated and useless operations which they directed, succeeded in detecting the principles on which they were constructed, and in explaining their use and signification. The date of these tables corresponds to the 21st of March in the year 638 of our era. They suppose two species of years, the solar tropical year, which they make to consist of 365 days 5 hours 50 min. and 4 sec., and the solar anomalistic year, that is, the period in which the sun returns to its apogee, which they estimate at 365 days 6 hours 12 min. 36 sec. This determination of the length of the solar year is too great only by 1 min. 15 sec. By means of the same tables the longitudes of the sun and moon are determined with considerable accuracy. They contain a correction for the sun's mean place, which corresponds to the equation of the centre. At 90° from the apogee, where the inequality of the sun's motion is greatest, they estimate the requisite correction at 2° 12′, which is about 16′ too great. This determination deserves to be particularly remarked, because, on account of a secular inequality of the eccentricity of the sun's orbit, there was once a time when the greatest value of the equation of the centre was nearly 2° 12′; and this fact is adduced as a proof of the remote antiquity of the observations from which the tables in question have been constructed. These tables suppose the apogee to retain always the same position relatively to the fixed stars; in reality it advances or gains on the stars about 10″ annually; but the supposition is still much nearer the truth than in the system of Ptolemy, where the apogee is supposed to be absolutely at rest with regard to the plane of the sun's orbit, and consequently to fall back among the stars by the whole quantity of the precession of the equinoxes, or about 50″ annually. With regard to the motions of the moon, they are deduced from a period of 19 years, in which are comprehended nearly 235 lunations; so that the cycle of Meton appears to have been known in Siam as well as in China. The moon's apogee is supposed to have been in the beginning of the movable zodiac 621 days after the epoch of the 21st of March 638, and to make an entire revolution in the heavens in the space of 3232 days. The first of these suppositions agrees with Mayer's tables to within a degree, and the second differs from them only by 11 hours 14 min. 31 sec. They contain only one correction for the two principal inequalities of the moon's motion, the equation of the centre and the evection.

A second set of Indian tables was sent from Chrisnabouram, a town in the Carnatic, by Father Du Champ, to De Lisle, about the year 1750. They are fifteen in number. They give the mean motions of the sun, moon, and planets; equations of the centre for the sun and moon; and two corrections for each of the planets, one of which corresponds to the apparent, the other to the real inequality. The epoch of these tables is not so ancient as that of the former. It corresponds to the 10th of March, at sunrise, in the year 1491 of our era, when the sun and moon were in conjunction.

A third set of astronomical tables was sent from India by Father Patonillet, and received by De Lisle about the same time with those of Chrisnabouram. These have not the name of any particular place affixed to them; but being calculated for the latitude of 16° 16′, Bailly thinks it probable that they came from Narsapour. Their epoch is midnight, between the 17th and 18th of March 1569.

The fourth and last set of Indian tables which we possess have been published in the Memoirs of the Academy of Sciences. They were communicated by a learned Brahmin of Tirvalore, a small town on the Coromandel coast, to the French astronomer Legentil, who had gone to India to observe the transit of Venus in 1769. The tables

History.

of Tirvalore, though somewhat different in form, present many points of resemblance with those formerly known in Europe. They suppose the same length of the year, the same inequalities of the sun and moon, and they are adapted nearly to the same meridian. But while they correspond with the other tables in these elements, they differ from them greatly in the antiquity of their epoch, which goes back to the famous era of the Calyougham, that is, the beginning of the year 3102 before Christ.

Now, the only question to be determined with regard to the antiquity of the Indian astronomy is, whether this epoch is real or fictitious; that is, whether the state of the heavens at the commencement of the Calyougham, as assumed in these tables, was actually determined by observation, or computed backwards from observations of more modern date. The solution to this question can only be obtained from the internal evidence afforded by the tables themselves; by examining whether the elements and precepts which they furnish are of sufficient accuracy to enable the places of the sun, moon, and planets to be calculated through a period of 44 centuries, without involving errors which the refined accuracy of the modern tables furnishes the means of detecting. A comparison of the Indian with the modern tables has been made at great length by Bailly, who imagines that he finds ample evidence of the reality of the era in question, and of the existence of an astronomy prior to that period, hardly yielding in accuracy to that which modern science has built on the theory of universal gravitation. The theory of Bailly has been adopted, and put forth with additional clearness and evidence, by the late Professor Playfair. One of the principal arguments which these illustrious authors bring forward in support of it is founded on the longitudes of the sun and moon. The mean place of the moon at the commencement of the Calyougham, that is, at midnight, between the 17th and 18th of February 3102 B. C., is stated by the Indian tables to be 306°. Her mean place, computed from Mayer's tables, without taking into account the acceleration, with which the Indians in the 15th century were of course unacquainted, is 300° 51′ 16″. Hence there would be a discrepancy of 5° 8′ 44″. But, according to the theory and last tables of Laplace, the moon, in virtue of the acceleration of her mean motion, has passed over an arc of very nearly 6° more than she would have done had her mean motion continued uniform from the period of the Calyougham to the date of Mayer's tables. This added to 300° 51′ 16″ gives 306° 51′ 16″ for the mean longitude of the moon at the epoch of the Calyougham, differing from the Indian determination by only 51′ 16″. Now, it is argued that this is a degree of accuracy which could have been reached only by actual observation, especially since, if the tables had been computed backwards, the error arising from the acceleration alone would have amounted to more than 5°. Bailly computes the place of the moon at the same epoch, from all the tables, Greek and Arabian, to which the Indians can be supposed to have had access, and the discrepancies are so great as to render his conclusion almost inevitable, that the Indian tables could not possibly have been drawn from such sources. The tables of Ptolemy make the moon's longitude at that time 11° 52′ 7″ greater than the Indian tables; and those of Ulugh-Beigh, constructed at Samarcand in 1437, give a difference of 6° also in excess.

Similar results are obtained from the consideration of other elements. According to the tables of Tirvalore, the tropical year consists of 365 days 5 hours 50 min. 35. sec. Lacaille makes it 365 days 5 hours 48 min. 49 sec. The difference is 1 min. 46 sec. Now the tropical year, being affected by the precession of the equinoxes, is subject to a secular inequality, which, according to the theory of Lagrange, renders it actually shorter by 40·5 sec. at the present time than it was at the commencement of the Calyougham. The error of the Indian tables is thus reduced to 1 min. 5·5 sec. In like manner, the obliquity of the ecliptic, which has been gradually diminishing during a great number of centuries, is supposed in the Indian tables to be greater than it is now found to be by observation. The Brahmins estimate it at 24°. The formula of Lagrange makes the variation, in 4800 years, amount to 22′ 32″. This therefore must be added to its obliquity in 1700, that is, to 23° 28′ 41″, in order to have the true obliquity at the commencement of the Calyougham. The sum is 23° 51′ 13″, and falls short of the Indian determination by 8′ 47″. We shall mention only another element, the equation of the centre of the sun. Bailly calculates that, according to the theory of Lagrange, the equation of the sun's centre, at the epoch of the tables, was 2° 6′ 28″. The Indians make it 2° 10′ 32″. The difference is only about 4′, and incomparably less than could have resulted from calculation by any methods which we can suppose the Indians to have possessed.

These arguments, it must be admitted, are exceedingly specious, but they are not by any means convincing. Even with the best modern tables we could not, as Bailly himself acknowledges, answer for the accuracy of the places of the sun and moon computed for so remote an epoch. The corrections for the secular inequalities amount in that long period to considerable quantities; and these corrections are deduced by theory from elements with respect to which there exists great uncertainty. And if we cannot be sure of the true places by computing backwards from our own tables, with what degree of confidence can we pronounce upon the accuracy of the places assigned in the tables of the Indians? It may be said that comparisons of this kind can never be supposed to give results perfectly alike. Granted: but if the discrepancies are such that the lapse of a thousand years more or less is required to establish a rigorous conformity, what becomes of the famous epoch of the Calyougham? Some of the elements of the Indian tables could not have the values assigned to them but at a long period before that epoch. In order to find their equation of the sun's centre, for example, it is necessary, according to the results of modern theory, to go back to 6000 years before our era. The argument, therefore, proves too much, and is consequently inconclusive. The different sets of tables of which we have spoken are closely allied with each other, and the most probable supposition is, that they are all derived from those of Chrisnabouram, of which the epoch is 1491. At that era the Indians were acquainted with the instruments, the geometry, and the researches of the Arabians and Greeks. Through this channel the tables seem to have come into their possession. The Brahmins adapted them to their own particular methods of computation, and threw back their epoch to the period when, according to these tables, all the planets were in conjunction with the sun. Every circumstance connected with the science of the Indians conspires to give us the humblest ideas of its value. Their methods of computation are encumbered with the unnecessary multiplications and divisions of enormous numbers, endless additions, subtractions, and reductions, for the purpose of obtaining numbers which could be put into technical verses, and even adapted to songs; so that the astronomer might be enabled to effect his calculations from memory alone, without its being necessary to have

recourse to tables or books. But simple and rude as these methods are, if they were really invented by the Brahmins, the science of that people must have greatly retrograded; for at present they merely follow a blind routine, utterly ignorant of theory, or the principles on which their processes are founded. Their astronomy, whether of ancient or recent origin, has produced no effect whatever on that of Europe; it has no filiation or connection with the science of the present day, and therefore has no other claim on our attention than such as may result from motives of mere curiosity.[1]

Astronomy of the Greeks.

The origin of astronomy in Greece, as in other early nations, ascends beyond the period of authentic history, and is concealed amidst the fables and traditions of the remotest times. During the darkness of the heroic ages some gleams of an acquaintance with the motions of the stars occasionally burst forth; and some traces appear of astronomical observations, probably derived from Egypt, the country which also furnished Greece with its gods and its arts. The Greeks seem to have divided the heavens into constellations about 13 or 14 centuries before the Christian era; for the sphere of Eudoxus, which is probably one of the fruits of the famous voyage of the Argonauts, must be referred to that period. Their early attention to the appearances of the heavens is sufficiently attested by their mythological fables, the greater part of which are only allegories of the celestial motions, and of the operations of nature. The lively fancy and brilliant imagination of this ingenious people strewed flowers in the most rugged paths, and spread agreeable images over the driest and most uninviting subjects: hence the sky was quickly covered with legends of the loves and exploits of gods and heroes. It would be foreign to our present purpose to enter into an enumeration of these fables, or attempt to trace their connection with the first dawnings of astronomy: we shall content ourselves with barely alluding to Uranus, to Atlas and his son Hesperus, who gave his name to the planet Venus; also to his daughters the Atlantides, from whom the Pleiades received their appellation; to Endymion, who, on the summit of Mount Latmos, held nocturnal converse with the chaste Diana; to Hercules; and Chiron the centaur, who taught men the use of the constellations; Musæus, who imagined the figures of men and animals which cover the celestial sphere; Orpheus and Linus, who explained the theogonies; Atreus, from whose banquet the sun fled back with horror; and Tiresias, who was struck blind for having witnessed some secret of the gods.

Thales, born 640 B.C.

The true foundations of Grecian science were laid by Thales, who was born at Miletus 640 years before our era. He was descended from an illustrious family, which had formerly reigned in Phœnicia, and inherited an ample fortune, which he expended in collecting the expiring embers of oriental science. Instigated by the love of knowledge, he travelled first into Crete, and afterwards into Egypt, where he was initiated into the mysteries of the priests, to whom, in return, he is said to have taught the method of measuring the height of the pyramids by comparing their shadows with those of known objects. Returned to his own country, he publicly taught the truths he had collected during his travels, and formed a sect which has been distinguished by the title of the *Ionian School.* His doctrines regarding astronomy contain a few truths which do honour to his sagacity and observation, though they are mixed with much error and absurdity. He taught that the stars are formed of fire; that the moon receives her light from the sun, and is invisible at her conjunctions, because she is hid in the sun's rays. He also taught the sphericity of the earth, which he placed at the centre of the world. He divided the sphere into five zones, by the arctic and antarctic circles, and the two tropics; and held that the equator is cut obliquely by the ecliptic, and perpendicularly by the meridian. He is also said to have observed eclipses; and Herodotus relates that he predicted the famous one which put a stop to the war between the Medes and the Lydians. It does not appear, however, that he ventured to assign either the day or the month of the eclipse, so that his prediction must have been confined to the year. According to Callimachus, he determined the positions of the stars which form the Lesser Bear, by which the Phœnicians guided themselves in their voyages. It is difficult, however, to conceive how Thales, unacquainted with instruments, could determine the positions of stars with so much accuracy as to render any essential assistance to the navigator. It is probable that he only pointed out the configuration, and some of the more brilliant stars of that constellation, among which he might remark that which is nearest the pole of the world.

Anaximander, born 610 B.C.

Thales was succeeded by Anaximander, to whom is also attributed the invention of the sphere, and the knowledge of the zodiac. According to Diogenes Laertius, he supposed, like his master Thales, the earth to be spherical, and placed at the centre of the universe; but Plutarch ascribes to him the less philosophical opinion of its resemblance to a column. He supposed the sun to be of equal magnitude with the earth. He invented the gnomon, and placed one at Lacedæmon to observe the solstices and equinoxes. But the circumstance which does most honour to Anaximander, and which entitles him to the gratitude of posterity, is the invention of geographical charts. He is said also to have believed in the plurality of worlds,—a sublime idea, which was adopted by almost every succeeding philosopher of Greece.

Anaximenes, born 530 B.C.

Anaximenes succeeded Anaximander in the Ionian school, and maintained nearly the same doctrines. Pliny says he was the first who taught the art of constructing dials,—an invention which, as we have just seen, has also been ascribed to Anaximander. These two philosophers probably revived the knowledge of an instrument the use of which had been forgotten amidst the general rudeness and ignorance of their countrymen. Before their time the Greeks only marked the divisions of the day by the different lengths of the sun's shadow.

Anaxagoras, born 500 B.C.

Anaxagoras was the disciple and successor of Anaximenes. If this philosopher really entertained the ridiculous opinions ascribed to him by Plutarch, the Ionian school must rather have retrograded than advanced in sound philosophy from the time of Thales. He is said to have believed that the sun is a mass of red-hot iron, or of heated stone, somewhat bigger than the Peloponnesus,—that the heaven is a vault of stones, which is prevented from tumbling only by the rapidity of its circular motion,—and that the sun is prevented from advancing beyond the tropics by a thick and dense atmosphere, which forces

[1] For an account of the Indian astronomy, see Bailly, *Astronomie Indienne;* also a Memoir by Professor Playfair, in the *Edinburgh Transactions*, vol. ii., or in the 3d volume of his Works; and the Papers of Jones, Bently, and Davis, in the *Calcutta Memoirs.* The theory of Bailly is most satisfactorily refuted by Delambre. See his *Histoire de l'Astronomie Ancienne*, tom. i

History.

him to retrace his course. These absurd notions are probably greatly exaggerated; but it does not appear that Anaxagoras contributed much to extend the knowledge of the heavens. A melancholy interest is, however, excited in his behalf, on account of the persecution which he suffered in consequence of his liberal opinions and his disregard for the superstitious notions of his age. Having shown the reason of the eclipses of the moon, he was accused of ascribing to natural causes the attributes and power of the gods. Having taught the existence of only one God, he was accused of impiety and treason towards his country. Sentence of death was pronounced on the philosopher and all his family; and it required the powerful interest of his friend and disciple Pericles to obtain a commutation of this iniquitous sentence into one of perpetual banishment.

Pythagoras, born 580 B.C.

While the Ionian sect was so successfully employed in cultivating and propagating a knowledge of nature in Greece, another, still more celebrated, was founded in Italy by Pythagoras. This renowned philosopher was in early youth a disciple of Thales. In quest of knowledge, which in those days could only be obtained by visiting the sages of foreign lands, he travelled into Egypt, Phœnicia, Chaldea, and India, where his memory is said still to subsist. Through the favour of Amadis, king of Egypt, to whom he was recommended by Polycrates, the tyrant of Samos, he was admitted into the sacred college at Memphis, though with great reluctance on the part of the priests. The severe ordeal through which these charlatans compelled him to pass, before they would consent to initiate him into their mysteries, was sufficient to have deterred the most courageous votary of knowledge; and Pythagoras was probably the only stranger who ever succeeded in fully exploring their secrets. After an absence of thirty years he returned to Greece, and began to give instructions in his native island of Samos. Soon after, he passed over to the Grecian colony established at Tarentum in Italy, and settled at Crotona, where he speedily acquired a splendid reputation. He was the first who assumed the modest title of *philosopher*, or lover of wisdom: formerly those who devoted themselves to the acquisition of learning were called *sophists* or *sages*.

Pythagoras is said to have acquired in Egypt the knowledge of the obliquity of the ecliptic, and that of the identity of the morning and evening stars. What he chiefly deserves to be commemorated for in the history of astronomy, is his philosophical doctrine regarding the motion of the earth. He taught publicly that the earth is placed at the centre of the universe; but among his chosen disciples he propagated the doctrine that the sun occupies the centre of the planetary world, and that the earth is a planet circulating about the sun. This system, which still retains his name, being called the old or Pythagorean system of the universe, is that which was revived by Copernicus. It is, however, only just to the memory of this last mentioned great man to observe, that there is a vast difference between the bare statement of the possibility of a fact, and the demonstration of its existence by irrefragable arguments. Pythagoras having remarked the relation which subsists between the tone of a musical chord and the rapidity of its vibration, was led by analogy to extend the same relation to the planets, and to suppose that they emit sounds proportional to their respective distances, and form a celestial concert too melodious to affect the gross organs of mankind. Another fancy into which he was led by his passion for analogies, was the application of the five geometrical solids to the elements of the world. The cube symbolically represented the earth; the pyramid, fire; the octaedron, air; the icosaedron, or twenty-sided figure, water; and the dodecaedron, or figure with twelve faces, the exterior sphere of the universe. Pythagoras left no writings; and it is doubtful whether he really entertained many of the opinions and reveries which have usually been ascribed to him.

Philolaus.

Philolaus of Crotona, a disciple of Pythagoras, embraced the doctrine of his master with regard to the revolution of the earth about the sun. He supposed the sun to be a disk of glass which reflects the light of the world. He made the lunar month consist of $29\frac{1}{2}$ days, the lunar year of 354 days, and the solar year of $365\frac{1}{2}$ days.

Nicetas.

Nicetas of Syracuse seems to have been the first who openly taught the Pythagorean system of the universe. Cicero, on the authority of Theophrastus, the ancient historian of astronomy, gives him the credit of maintaining that the apparent motion of the stars arises from the diurnal motion of the earth about its axis;[1] but this rational doctrine seems to have been first broached by Heraclides of Pontus, and Ecphantus, a disciple of Pythagoras.

Metonic cycle, 433 B.C.

The introduction of the Metonic cycle forms an era in the history of the early astronomy of Greece. The Chaldeans, as we have already stated, established several luni-solar periods; and the difficulty of reconciling the motions of the sun and moon, or of assigning a period at the end of which these two luminaries again occupy the same positions relatively to the stars, had long embarrassed those who had the care of regulating the festivals. Meton and Euctemon had the honour of first obviating this difficulty, at least for a time; for the motions of the sun and moon being incommensurable, no period can be assigned which will bring them back to precisely the same situations. These two astronomers formed a cycle of nineteen lunar years, twelve of which contained each 12 lunations, and the seven others each 13, which they intercalated among the former. It had long been known that the synodic month consisted of $29\frac{1}{2}$ days nearly; and in order to avoid the fraction, it had been usual to make the twelve synodic months, which compose the solar year, to consist of 29 and 30 days alternately; the former being called *deficient* and the latter *full* months. Meton made his period to consist of 125 full and 110 deficient months, which gives 6940 days for the 235 lunations, and is nearly equal to 19 solar years. This cycle commenced on the 16th of July in the year 433 B.C. It was received with acclamation by the people assembled at the Olympic games, and adopted in all the cities and colonies of Greece. It was also engraved in golden letters on tables of brass, whence it received the appellation of the *golden number*, and has been the basis of the calendars of all the nations of modern Europe. It is still in ecclesiastical use, with such modifications as time has rendered necessary.

Eudoxus 370 B.C.

Eudoxus of Cnidus, about the year 370 B.C., obtained great reputation as an astronomer. According to Pliny, he introduced the year of $365\frac{1}{4}$ days into Greece. Archimedes says that he supposed the diameter of the sun to be nine times greater than that of the moon, which shows that he had in some degree overcome the illusions

[1] "Nicetas Syracusius, ut ait Theophrastus, cœlum, solem, lunam, stellas, supera denique omnia, stare censet; neque, præter terram, rem ullam in mundo moveri; quæ cum circum axem se summa celeritate convertat et torqueat, eadem effici omnia, quasi, stante terra, cœlum moveretur." (Cicero, *Acad. Quæst.*; *Opera*, tom. iv. p. 39, edit. Bipont.) Copernicus himself could not have stated the doctrine with greater precision.

History.

of sense. The titles of three of his works have been preserved—the *Period or Circumference of the Earth*, the *Phenomena*, and the *Mirror*. His observatory was still standing at Cnidus in the time of Strabo. His memory deserves to be honoured for the contempt which he evinced for the Chaldean predictions, and for having contributed to separate true astronomy from the reveries of judicial astrology. Eudoxus seems to have been the first who attempted to give a mechanical explanation of the apparent motions of the planets. He supposed each planet to occupy a particular part of the heavens, and that the path which it describes is determined by the combined motion of several spheres performed in different directions. The sun and moon had each three spheres; one revolving round an axis which passes through the poles of the world, and which occasions the diurnal motion; a second revolving round the poles of the ecliptic, in a contrary direction, and causing the annual and monthly revolutions; the third revolving in a direction perpendicular to the first, and causing the changes of declination. Each of the planets had a fourth sphere to explain the stations and retrogradations. As new inequalities and motions were discovered, new spheres were added, till the machinery became so complicated as to be altogether unintelligible.

Plato.

Although Plato can hardly be cited as an astronomer, yet the progress of the science was accelerated by means of the lights struck out by his sublime and penetrating genius. He seems to have had just notions of the causes of eclipses; and he imagined that the celestial bodies originally moved in straight lines, but that gravity altered their directions, and compelled them to move in curves. He proposed to astronomers the problem of representing the courses of the stars and planets by circular and regular motions. Geometry was assiduously cultivated in the school of Plato; and on this account he claims a distinguished place among the promoters of true astronomy.

Aristotle, born 384, died 321, B.C.

Astronomy is also under some obligations to Aristotle. In a treatise which he composed on this science, he recorded a number of observations which he had made; and, among others, mentions an eclipse of Mars by the moon, and the occultation of a star in the constellation Gemini by the planet Jupiter. As such phenomena are of rare occurrence, their observation proves that he had paid considerable attention to the planetary motions.

A great number of astronomers about this time appear on the stage, whose labours and observations prepared the way for the reformation of the science which was shortly after effected by Hipparchus.

Helicon.

Helicon of Cizicene is renowned for the prediction of an eclipse, which took place, as Plutarch affirms, at the time announced. History records the names of only three individuals in ancient Greece who predicted eclipses, Thales, Helicon, and Eudemus.

Eudemus.

Eudemus composed a history of astronomy, a fragment of which, consisting of only a few lines, is preserved by Fabricius in the *Bibliotheca Græca*. In this it is mentioned that the axes of the ecliptic and equator are separated from each other by the side of a pentedecagon, which is equivalent to saying that they contain an angle of 24°. This is the first value which we find assigned by the Greeks to the obliquity of the ecliptic. It is given in round numbers, and may easily be supposed to contain an error of a quarter of a degree.

Calippus.

Calippus is celebrated for the period which he formed of four Metonic cycles. Having observed, by means of an eclipse of the moon which took place about six years before the death of Alexander, that the Metonic cycle contained an error of a fourth of a day, he introduced the period of 940 lunations, containing four Metonic cycles, diminished by one day. He likewise formed a collection of observations on the heliacal risings of the planets.

Theophrastus.

Theophrastus wrote a history of astronomy, and supposed the milky way to be produced by the imperfect junction of the two hemispheres, which allowed the light to penetrate from the firmament beyond.

Autolycus.

Autolycus of Pitaneas wrote two books, one on the movable sphere, the other on the risings and settings of the stars. These are the most ancient of the astronomical works of the Greeks which have come down to our times.

Pytheas.

Pytheas of Marseilles, about the time of Alexander the Great, determined the length of the solstitial shadows in various countries by means of the gnomon. He found the shadows equal at Marseilles and Byzantium—a circumstance which does not give a favourable idea of the accuracy of his observations, inasmuch as the difference of the latitudes of the two places amounts to $2\frac{1}{4}$ degrees. The observation is, however, interesting, as it is the most ancient of the kind which has been preserved after that of Tcheou-Kong, and as it confirms the successive diminution of the obliquity of the ecliptic. Pytheas undertook several voyages for the purpose of obtaining geographical and astronomical information, and advanced northwards as far as Iceland. His relations have been treated as fabulous by Strabo and Polybius, but the accuracy of the greater number of them has been confirmed by modern observation and experience. He was the first who distinguished the climates by the different lengths of the days and nights.

Astronomy in the School of Alexandria.

In the history of the various sects which have hitherto come under our review, we meet only with some useful remarks, with numerous hypotheses and conjectures, but with scarcely any appearance of regular and connected science. Up to this date the astronomical knowledge of the Greeks was confined to a few facts, the discovery of which implies no theory, and scarcely the aid even of the simplest instruments. The order and arrangement of the planets, the causes of eclipses, the identity of the morning and evening stars, the approximate length of the year, that of the lunar month, the obliquity of the ecliptic, and the cycles of Meton and Calippus, were almost the sole results of their astronomical speculations. In the Alexandrian school we meet for the first time with regular and systematic observations. We there find angular distances measured with appropriate instruments, and calculations made according to the rules of trigonometry.

After the premature death of Alexander, his principal generals shared among themselves his magnificent conquests, and Egypt fell to the lot of Ptolemy Soter. This prince was distinguished by an ardent love of science, and a desire to promote every species of liberal knowledge. He accordingly invited to his court, which he had established at Alexandria, the most eminent philosophers of Greece, and fixed them there by his liberality and munificent protection. His son, Ptolemy Philadelphus, who inherited his throne, also inherited his genius and love of science and learning. A superb edifice, styled the *Museum*, was assigned to the use of the men of science whom he had attracted to his capital, to which he also added an observatory, and the famous library, which had been collected with great care and at a vast expense by Demetrius Phalerius. The prince took great delight in the Museum; he visited it frequently, entered into familiar conversation with its inmates on the subject of their various pursuits, and by his own example stimulated their

History. zeal and encouraged their inquiries. This noble institution, which survived all the vicissitudes of nine centuries, was the means of conferring incalculable benefits on the human race; and the name of its founder, Ptolemy Philadelphus, will be gratefully remembered while science and learning occupy a place in the estimation of mankind.

Aristillus and Timocharis, 300 B. C. The first astronomers of the Alexandrian school were Aristillus and Timocharis, who flourished under the first Ptolemy, about 300 years before Christ. The chief object of their labours was the determination of the relative positions of the principal stars of the zodiac, instead of merely announcing their risings and settings, as had been the practice of the orientals and the ancient Greeks. The observations of these two astronomers conducted Hipparchus to the important discovery of the precession of the equinoxes, and served as the basis of the theory which Ptolemy, some centuries afterwards, gave of that phenomenon.

Aristarchus, B. C. 281. Aristarchus of Samos, the next in order of the Alexandrian astronomers, composed a treatise on the *Magnitudes* and *Distances* of the sun and moon, which has been preserved to our times. In this treatise he describes an ingenious method which he employed to obtain the relative distances of the two luminaries. At the instant when the moon is dichotomized, that is, when the exact half of her disk appears to a spectator on the earth to be illuminated by the sun's light, the visual ray passing from the centre of the moon to the eye of the observer is perpendicular to the line which joins the centre of the moon and sun. At that instant, therefore, he measured the angular distance of the two bodies, and finding it to be 87 degrees, he concluded, by the resolution of a right-angled triangle, that the distance of the sun is between eighteen and nineteen times greater than that of the moon. This method is perfectly correct in theory, but it is difficult to be assured of the exact instant of the moon's dichotomy, and in an angle of such magnitude a very small error greatly affects the result. The error of Aristarchus is very considerable, the true angle being about 87° 50′. The estimated distance of the sun is by consequence far too small; yet the determination, faulty as it was, contributed to expand greatly the existing notions relative to the boundaries of the universe, for the Pythagoreans had taught that the sun is only three, or at most three and a half times more distant than the moon. Another delicate observation made by Aristarchus was that of the magnitude of the sun's diameter, which, as we learn from Archimedes, he determined to be the 720th part of the circumference of the circle which the sun describes in his diurnal revolution. This estimate is not very far from the truth, and the observation is by no means an easy one. He embraced the doctrine of Pythagoras respecting the earth's motion, and appears to have entertained juster notions than any of the astronomers who preceded him, on the magnitude and extent of the universe. The treatise on the *Magnitudes* and *Distances* is published in the third volume of the works of Dr Wallis, with a Latin translation by Commandine, and some notes.

Eratosthenes, born 276 B. C. Eratosthenes, the successor of Aristarchus, was a native of Cyrene, and invited to Alexandria by Ptolemy Evergetes, who appointed him keeper of the royal library. He is supposed to have been the inventor of armillary spheres, a species of instrument extensively used by the ancient astronomers. By means of an instrument of this kind he observed the distance between the tropics to be to the whole circumference of a great circle as 11 to 83; a ratio equivalent to 47° 42′ 39″, half of which gives 23° 51′ 19·5″ for the obliquity of the ecliptic. This is a very important observation, and confirms the gradual diminution of the obliquity as indicated by theory. Eratosthenes is celebrated for being the first who attempted, on correct principles, to determine the magnitude of the earth. Having remarked, by some means with which we are unacquainted, that Syene, the most southern of the cities of ancient Egypt, is situated nearly on the same meridian with Alexandria, he conceived the idea of determining the amplitude of the celestial arch intercepted between the zeniths of the two places, and of measuring at the same time their distance on the ground; operations which would afford data for the determination of the whole length of the terrestrial meridian. Syene was known to be situated exactly under the tropic; for at the summer solstice the gnomon had no shadow, and the sun's rays illumined the bottom of a deep well in that city. On the day of the solstice he found the meridional distance of the sun from the zenith of Alexandria to be 7° 12′, or a fiftieth part of the circumference. It had also been ascertained by the *bematists* or surveyors of Alexander and the Ptolemies, that the itinerary distance between Alexandria and Syene was 5000 stadia; therefore $5000 \times 50 = 250{,}000$ stadia form the circumference of a great circle of the earth, or the length of the terrestrial meridian. Unfortunately, on account of the uncertainty respecting the length of the stadium here employed, we possess no means of estimating the degree of approximation afforded by this rude though ingenious attempt; but the idea does immortal honour to Eratosthenes, and the moderns have added nothing to his method: their better success is owing solely to the progress of the arts and the perfection of astronomical instruments.

About this time the science of astronomy was enriched by the discoveries of some of the distinguished geometricians whose labours have so greatly extended the glory of the Alexandrian school. Euclid, the celebrated author of the *Elements*, lived in the reign of the first Ptolemy. Euclid. He composed a book on the sphere, which probably served as a model for future works of the same kind, and was the first who treated in a geometrical manner of the phenomena of the different inclinations of the sphere. Conon of Samos, the friend of Archimedes, collected the records of eclipses, which had been observed by the ancient Egyptians; and Callimachus ascribes to him the constellation of Berenice's hair. Conon. Archimedes, whose profound genius and deep knowledge of geometry and mechanics entitle him to the appellation of the *Newton* of the ancients, also claims a high rank among the cultivators of astronomy. Archimedes. His celebrated planetarium, which represented the motions of the sun, moon, planets, and starry sphere, has been a frequent theme of the admiration and praises of the poets:

> *Jura poli, rerumque fidem, legesque deorum,*
> *Ecce Syracusius transtulit arte senex.*

Apollonius of Perga solved the important problem of the stations and retrogradations of the planets by means of epicyles and deferents; and he is entitled to the glory of having formed the alliance between the two sciences of geometry and astronomy, which has been productive of the greatest advantages to both. Apollonius.

Astronomy, which had as yet only consisted of a knowledge of isolated facts, acquired a systematic form, and almost a new existence, from the genius and assiduity of Hipparchus, one of the most astonishing men of antiquity, and perhaps the greatest of all in the sciences which are not purely speculative. Hipparchus, B. C. 140. This illustrious founder of astronomical science was born at Nice in Bythinia, and ob-

served at Rhodes. Flamsteed and Cassini, probably misled by some ambiguous expressions of Ptolemy, have related that his observations were made at Alexandria; and this opinion seems generally to have been adopted by historians. The question has been examined carefully, and at considerable length, by Delambre (*Astronomie Ancienne*), who comes to the conclusion that there is no reason whatever to infer that Hipparchus ever saw Alexandria. Ptolemy, in reporting the observations of Hipparchus, supposed Rhodes and Alexandria to be situated on the same meridian, and consequently does not find it necessary to mention the place at which the observations were made.

Hipparchus commenced his brilliant career by verifying the determination of the obliquity of the ecliptic made by Eratosthenes. He next directed his attention to the length of the tropical year. By comparing an observation of his own, of the summer solstice, with a similar one made by Aristarchus 140 years before, he found that the anciently received value of $365\frac{1}{4}$ days was too great by seven minutes. This leaves the tropical year a value still too great; but it is probable that the error arose from the inaccuracy of the observation of Aristarchus: for the observations of Hipparchus, compared with those of the moderns, make the length of the tropical year amount to 365 days, 5 hours, and 49 minutes, which is only 12 seconds greater than the truth. By a careful observation of the solstices and equinoxes, he discovered that the year is not divided by these points into four equal parts, the sun occupying $94\frac{1}{2}$ days in passing from the vernal equinox to the summer solstice, and only $92\frac{1}{2}$ from the same solstice to the equinox of autumn. The sun, consequently, remained 187 days in that part of the ecliptic which lies between the equator and the north pole, and therefore only about 178 in the other part. This observation led Hipparchus to the great discovery of the eccentricity of the solar orbit. He accounted for the apparent inequality of the sun's motion, by supposing that the earth is not placed exactly at the centre of the circular orbit of the sun, and that consequently his distance from the earth is subject to variation. When the sun is at his greatest distance, he appears to move more slowly; and when he approaches nearer, his motion becomes more rapid. The distance of the earth from the centre of the orbit is called the *eccentricity:* it produces an equation between the real and apparent motions, which is called the *equation of the centre.* He determined the magnitude of this equation in terms of the radius of the ecliptic, and fixed the position of the line of the apsides, or that which joins the two opposite points of the orbit which are at the greatest and least distance from the earth. With these data he formed the first tables of the sun which are mentioned in the history of astronomy. The discovery of the eccentricity also led Hipparchus to that of the inequality of the lengths of the solar days at different seasons of the year. In the interval which elapses between the sun's passage over the meridian and his return to it the following day, the sun advances by his own proper motion towards the east nearly a degree. But the rate of this motion is unequal, varying between 57 and 61 minutes of a degree; and the accumulation of the inequalities forms what is called the equation of time, that is, the difference between the true time, as shown by the sun, and the mean time, shown by a well-regulated clock, the motions of which are equal and uniform.

The attention of Hipparchus was next directed to the motions of the moon; and on this subject his researches were attended with equal success. From the comparison of a great number of the most circumstantial and accurate observations of eclipses recorded by the Chaldeans, he was enabled to determine the period of the moon's revolution relatively to the stars, to the sun, to her nodes, and to her apogee. These determinations are among the most precious relics of ancient astronomy, inasmuch as they corroborate the results of theory in one of its finest deductions—the acceleration of the mean lunar motion—and thus furnish one of the most delicate tests of the truth of Newton's law of gravitation. It was, indeed, by a comparison of the observations of Hipparchus with those of the Arabian and modern astronomers, that Dr Halley was led to the discovery of that curious and important phenomenon. Hipparchus also determined the eccentricity of the lunar orbit, and its inclination to the plane of the ecliptic; and the values which he assigned to these elements, making allowance for the evection and the inequalities of the moon's motion in latitude, are to a few minutes the same as those which are now observed. He had also an idea of the second inequality of the moon's motion, namely, the evection, and made all the necessary preparations for a discovery which was reserved for Ptolemy. He likewise approximated to the parallax of the moon, which he attempted to deduce from that of the sun, by determining the length of the frustum cut off from the cone of the terrestrial shadow by the moon when she traverses it in her eclipses. From the parallax he concluded that the greatest and least distances of the moon are respectively equal to 78 and 67 semi-diameters of the earth, and that the distance of the sun is equal to 1300 of the same semi-diameters. The first of these determinations exceeds the truth; the second falls greatly short of it, the distance of the sun being nearly equal to 24,000 terrestrial semi-diameters. It may, however, be remarked that Ptolemy, who undertook to correct Hipparchus with regard to the parallax, deviated still farther from the truth.

The apparition of a new star in the time of Hipparchus induced him to undertake the formation of a catalogue of all the stars visible above his horizon, to fix their relative positions, and mark their configurations, in order that posterity might have the means of observing any changes which might in future take place in the state of the heavens. This arduous undertaking was rewarded by the important discovery of the precession of the equinoxes. one of the fundamental elements of astronomy. By comparing his own observations with those of Aristillus and Timocharis, he found that the first point of Aries, which, in the time of these astronomers, or 150 years before, corresponded with the vernal equinox, had advanced two degrees, according to the order of the signs, or at the rate of 48 seconds a year. This determination is not very far from the truth; for, according to modern observations, the rate of the precession is about 50·1 seconds annually. His catalogue contained 1080 stars: it is generally, but erroneously, stated to have contained only 1022, after that of Ptolemy, in which the nebulous and some obscure stars are omitted. He also commenced a series of observations to furnish his successors with the means of forming a theory of the planets. Hipparchus likewise invented the planisphere, or method of representing the starry firmament on a plane surface, which afforded the means of solving the problems of spherical trigonometry in a manner often more exact and more commodious than the globe itself. He was the first who demonstrated the methods of calculating triangles, whether rectilineal or spherical; and he constructed a table of chords, from which he drew nearly the same advantages as we derive at present from the tables of sines. Geography is also indebted to him for the happy idea of fixing the position of places on

History. the earth by means of their latitudes and longitudes; and he was the first who determined the longitude by the eclipses of the moon.

These various labours and brilliant discoveries give a high idea of the industry and genius of Hipparchus. His writings have unfortunately all perished, excepting a commentary on the poem of Aratus; but the principal elements of his theories, together with a few observations, have been preserved in the Almagest of Ptolemy.

After the death of Hipparchus, nearly three centuries elapsed before any successor arose worthy of the name. During this long period astronomy gained no essential advancement. Some rude observations, scarcely superior to those of the Chaldeans, and a few meagre treatises, are the only monuments which exist to testify that science had not fallen into utter oblivion in an age so fertile of poets and orators. Geminus and Cleomedes wrote treatises, which have been preserved to our times; Agrippa and Menelaus are said to have observed; the Roman calendar was reformed by Julius Cæsar and the Egyptian astronomer Sosigenes; and Posidonius measured a degree, and remarked that the laws of the tides depend on the motions of the sun and moon.

Ptolemy, A. D. 130. Ptolemy was born at Ptolemais in Egypt, and flourished at Alexandria about the 130th year of our era, under the reigns of Adrian and Antoninus. This illustrious ornament of the Alexandrian school is entitled by his own discoveries to the high rank among astronomers which has universally been assigned to him; but the most signal service which he conferred on science was the collection and arrangement of the ancient observations. Out of these materials he formed the Μεγαλη Συνταξις, or *Great Composition*, a collection which exhibits a complete view of the state of astronomy in the time of Ptolemy, and which contains the germ of most of the methods in use at the present day.

The hypothesis which Ptolemy adopted for the purpose of explaining the apparent motions, was that which had been followed by Hipparchus. We have already seen that the genius of Pythagoras, soaring above the illusions of sense, had conceived the sun to be situated at the centre of the universe, and the earth to circulate, like the other planets, about the sun; and that the same opinion was entertained and supported by Aristarchus and a few other astronomers. It would seem, however, that this philosophical idea never gained much ground in antiquity, even among the learned. The vulgar prejudice respecting the immobility of the earth continued to prevail; and it had become an inveterate axiom, that all the celestial motions must be circular and uniform. Ptolemy himself, who felt in its full force the difficulty of reconciling the appearances with the notion of a uniform circular motion, adopted the common opinion without scruple as a primordial law of the universe; for, says he, this perfection belongs to the essence of celestial things, which neither admit of disorder nor irregularity. To save this chimera—the uniform circular motion—Apollonius imagined the ingenious apparatus of epicycles and deferents; and Hipparchus advanced a step farther, by placing the centre of the sun's circle at a small distance from the earth. Ptolemy adopted both hypotheses, and supposed the planet to describe an epicycle by a uniform revolution in a circle, the centre of which was carried forward uniformly in an eccentric round the earth. By means of these suppositions, and by assigning proper relations between the radii of the epicycle and deferent circle, and also between the velocity of the planet and the centre of its epicycle, he was enabled to represent with tolerable accuracy the apparent motions of the planets, and particularly the phenomena of the stations and retrogradations, which formed the principal object of the researches of the ancient astronomers. The notions of Apollonius and Hipparchus were thus reduced to a systematic form, and the proportions of the eccentrics and epicycles of all the planets assigned, by Ptolemy; on which account the system has been generally ascribed to him, and obtained the name of the *Ptolemaic System* of the universe. As a first attempt to bring the celestial motions within the grasp of geometry, it does infinite honour to the genius of its inventors. It is, however, totally irreconcilable with the precision of modern observations; for it is impossible to represent on this hypothesis the variations of the distances of the planets at the same time with their apparent motions. But this difficulty could scarcely be felt by Ptolemy, inasmuch as it was impossible, before the invention of the telescope and micrometer, to form any accurate estimate of the variations of the apparent diameter of a planet, and consequently of its distance. It must be admitted, however, that the Ptolemaic hypothesis might be sufficient for the wants of practical astronomy, that is, for calculating the places of the planets and forming tables of their motions, were it not for its extreme complication. The discovery of every new irregularity in the planetary motions exacts the addition of a new epicycle; and such was the confusion resulting from this circumstance, that Alphonso X., despairing of being able to comprehend the complicated machinery, was tempted to exclaim, that if the Deity had called him to his counsels at the creation of the world, he could have given good advice. Yet, notwithstanding all its defects, the system of Ptolemy gained a complete ascendency over the minds of mankind, and, so difficult is it to leave the beaten path, continued to be implicitly followed by every astronomer during fourteen centuries, having been only finally exploded by Kepler's discovery of the elliptic orbit of Mars.

The most important discovery which astronomy owes to Ptolemy is that of the *Evection* of the moon. Hipparchus had discovered the first lunar inequality, or the equation of the centre, which serves to correct the mean motion at the syzygies, and had also remarked the necessity of another correction for the quadratures. He even undertook a set of observations, with a view to ascertain its amount and its law; but death put a stop to his labours before he had brought them to a successful issue. Ptolemy completed the investigation, and discovered that the eccentricity of the lunar orbit is itself subject to an annual variation, depending on the motion of the line of the apsides. The variation of the position of the apsides produces an inequality of the moon's motion in her quarters, which has been technically denominated the evection. The equation given by Ptolemy, though of course empirical, is remarkably exact.

Ptolemy employed a very simple process for determining the moon's parallax, which was probably suggested to him by the situation of Alexandria, where he observed. He determined the latitude of a place a little to the south of that city, over the zenith of which the moon was observed to pass when her northern declination was the greatest possible. But when the moon is in the zenith, or in the same straight line with the observer and the centre of the earth, she has no parallax; consequently the obliquity of the ecliptic and the latitude of the station being known, the moon's greatest northern latitude was also determined. The next step was to observe the moon's meridian altitude fifteen days after the first observation, when her southern latitude was necessarily the greatest possible. This observation gave the *apparent* altitude of the moon, but her greatest northern and southern decli-

History. nations being supposed equal, her *true* altitude, as seen from the centre of the earth, was easily computed from the previous observation, and the difference between the true and apparent altitudes gave the amount of the parallax.

The observations of Hipparchus relative to the motion of the stars in longitude, or the regression of the equinoctial points, were confirmed by Ptolemy, although he mistook its amount, and diminished a quantity which Hipparchus had already estimated too low. According to Hipparchus, the regression is at the rate of two degrees in 150 years. Ptolemy reduced it to one degree in 90 years. This disagreement would seem to indicate an error of more than a degree in the observations, which can with difficulty be admitted, considering the accordance which subsists among the different observations cited by Ptolemy in support of his own determination. For this and some other reasons Ptolemy has been accused of altering the observations of Hipparchus, and accommodating them to his own theory; but there does not appear to be any just ground for the imputation. The error with regard to the regression probably arose from the circumstance, that Hipparchus had assigned too great a value to the length of the year, whence the motion of the sun with regard to the equinoxes would be made too slow, and the longitudes employed by Ptolemy consequently diminished.

Ptolemy has been called the *Prince* of astronomers,—a title which may perhaps be justified by the universal and long-continued prevalence of his system, but to which he has no claim from the number or value of his own observations. After a laborious and minute examination of the Almagest, Delambre doubts whether any thing, saving the author's declarations, is contained in that great work, from which it can be decisively inferred that Ptolemy ever observed at all. He indeed frequently makes mention of observations made by himself; but his solar tables, rate of the precession, eclipses, determination of the moon's motion and parallax, and, above all, his catalogue of stars, render it impossible to doubt that the greater part of the results which he has given as observations are merely computed from the tables of Hipparchus. It is therefore difficult to allow to Ptolemy that good faith and "astronomical probity which forms one of the most indispensable qualities of an observer." He never in any instance cites a single observation more than is just necessary for the object he has immediately in view, and consequently, by precluding all comparison of one observation with another, has deprived us of the means even of guessing at the probable amount of the errors of his solar, lunar, and planetary tables. If an astronomer, as Delambre justly remarks, were to adopt the same course at the present day, he would be certain of forfeiting all claim to confidence; but Ptolemy stood alone; he had neither judges nor rivals; he claimed admiration, and received it; and now no one condescends to calculate the few observations he has left us. (Delambre, *Astronomie Ancienne*, tom. i. Discours Préliminaire.) His catalogue contains only 1029 stars, and is therefore less extensive than that of Hipparchus, but it is exceedingly valuable on account of its details.

The name *Almagest* (Μεγίστη, with the Arabic prefix) was bestowed on the *Syntax* by the Arabians, into whose language it was translated in the ninth century. The first Latin translation was from the Arabic, and published at Venice in 1515. It abounds in Arabic words and idioms, and is very inaccurate and barbarous. The second Latin translation was made from the original Greek by George of Trebizond, and is greatly superior to the first. It was published at Basle in 1541, and in 1551. The Greek text was published at the same time in 1538. History

Ptolemy was the author of numerous other works connected with astronomy, of which his *Geography*, in eight books, is the best known. It contains a list of all the places of which the latitudes and longitudes had at that time been determined. His treatise on *Optics* was supposed to be lost, till an imperfect Latin translation, from an Arabic version, was lately discovered in the king's library at Paris. The last book of this work contains a theory of astronomical refraction, more complete than any which existed before that of Cassini. It would seem that Ptolemy had not discovered the refraction at the time he composed the Almagest, no mention being made of the subject in that work. The explanation which he gives of the phenomenon is natural and satisfactory, indeed entirely conformable with that which is now universally adopted. The idea and explanation remained buried in the *Optics* till reproduced by Alhazen; but neither Ptolemy nor Alhazen attempted to estimate the amount of the refraction. His *Planisphere* and *Analemma*, in which he treats of the stereographic and orthographic projections of the sphere, show a perfect acquaintance with spherical trigonometry. In the last-mentioned work he makes use of the sines, and his constructions comprehend three of the four general theorems in modern use. Divers treatises also on music, dialling, chronology, and mechanics, attest the universality of Ptolemy's genius, and his unremitting application to the pursuits of science. Like Archimedes, he had a desire to transmit to posterity the history of his labours by a public monument. In the temple of Serapis, at Canopus, he is said to have consecrated a marble pillar, with an inscription containing the principal elements of his astronomy, such as the length of the year, the eccentricity of the solar and lunar orbits, the dimensions and forms of the epicycles of the planets, &c.

Decline of astronomy.

On the death of Ptolemy astronomy ceased to be cultivated among the Greeks. The Alexandrian school subsisted indeed for some centuries after; but genuine science had fled, and its place been usurped by the vain wranglings of theologians and grammarians. During the long period of six or seven centuries, the labours of those who assumed the name of astronomers were confined to needless or trifling commentaries on the works of Hipparchus and Ptolemy, and were productive of no observations, or even remarks, having a tendency to enlarge the boundaries of the science. The genius of the Roman dominion was unfavourable to the development or exercise of the higher faculties of the human intellect; and the natural sciences, with the liberal arts, faded away under the withering influence of military despotism.

From the brief account which has now been given, it will be easily inferred that the Greeks cultivated astronomy rather as a speculative than a practical science. None of their numerous sects ever evinced any taste for observation or experiment; and hence, while geometry made great and rapid advances in their hands, physics and experimental philosophy were entirely neglected. The prevailing passion for speculation pervaded even their astronomy. They explained the doctrine of the sphere, and the apparent motions of the planets; and framed ingenious theories to account for such phenomena as came immediately under the cognizance of their senses; but if we except the observations of Hipparchus and Ptolemy, and perhaps two solstitial distances of the sun from the zenith, observed by Eratosthenes, we remark among them no observations made with instruments capable of measuring angular distances. Before Hipparchus, no mention is made of the astrolabe; and the recorded determinations do not

History.

give us a very favourable idea of the accuracy of that instrument. On casting our eyes over the catalogue of Ptolemy, we scarcely ever meet with a fraction of a degree smaller than one-twelfth, that is to say, less than five minutes; whence we may infer that the astrolabe only measured twelfth parts of a degree. Occasionally, indeed, the fractions one-fourth and three-fourths occur; but these were most probably inserted by estimation. The Greeks of Alexandria committed an error of no less than 15′ with regard to the altitude of the pole, one of the most essential elements to an observer; and it does not appear that they were ever able to determine the time to within a quarter of an hour. Yet notwithstanding these circumstances, which indicate that the art of observation was still in its infancy, the science of astronomy is vastly indebted to the labours and speculations of the Greeks. The complicated but ingenious hypotheses of Ptolemy prepared the way for the elliptic orbits and laws of Kepler, which, in their turn, conducted Newton to the great discovery of the law of gravitation.

Astronomy of the Arabians.

While the nations of western Europe were involved in the thickest shades of ignorance and barbarism, the torch of science was rekindled, and blazed forth with extraordinary splendour, among the Saracens. The burst of fanaticism which enabled the followers of Mahomet to carry their religion and their arms over the fairest portion of the ancient world subsided, in a great measure, after a century and a half of uninterrupted conquest, and was succeeded by a period of repose, during which they cultivated the arts of peace and civilisation with the same ardour which had characterized their achievements in arms. Under the enlightened and munificent protection of the caliphs, Bagdat became what Alexandria had been under the Ptolemies, the centre of politeness and knowledge.

The accounts which we possess of the Saracen literature are imperfect and scanty; but the first of the caliphs who appears to have encouraged the study of astronomy was Abougiafar, surnamed Almansor, or the Victorious, who reigned in the eighth century. His grandson Almamon, the seventh of the Abassides, and second son of the famous Haroun Al Raschid, who reigned at Bagdat from 813 to 833, is celebrated for the protection which he gave to learning, and the zeal with which he laboured to propagate the sciences of the Greeks among his subjects. In granting peace to the emperor Michael III., he stipulated for liberty to collect in Greece all the writings of the philosophers. These he transported into his own country, and caused to be translated into Arabic. Finding it mentioned in the geography of Ptolemy that a degree of the earth was equivalent to 500 stadia, he resolved to have this fact verified by a new measurement; and in obedience to the commands of the caliph, a company of mathematicians assembled in the spacious plain of Sinaar, where, having observed the altitude of the pole, they separated themselves into two parties, and proceeded in opposite directions along the meridian, measuring the distance they passed over till the altitude of the pole varied one degree. Being unacquainted with the nature of the instruments made use of in these geodetic operations, we cannot estimate the probable accuracy of the result; but as it agreed perfectly with the statement of Ptolemy, we have a right to infer that the measurement was executed in a very inadequate manner, and that the mathematicians of the caliph adopted the ancient determination from want of confidence in their own.

The *Syntax* of Ptolemy was translated into Arabic under the reign of Almamon, by Isaac Ben Honain. The translation was afterwards revised by Thabet or Thebith Ben Korah, and it was about this time that it received the appellation of Almagest. Astronomical observations, which, as we have had occasion to remark, had been greatly neglected by the successors of Hipparchus, formed a principal object of the attention of the Arabians. By the orders of Almamon, the obliquity of the ecliptic was observed, and found to be 23° 33′. According to the modern tables, the obliquity at that time was 23° 36′ 34″, so that the error was less than that of Hipparchus and Ptolemy, in their determination of the same element. This observation supposes instruments of some accuracy. Among the astronomers whom Almamon drew to his court, we find the names of Habash of Bagdat, who composed three books of astronomical tables; Ahmed, or Mohammed Ben Cothair, better known by the name of Alfragan, or Alfranius, who, from his great expertness in computing, was styled the *calculator*. He composed an elementary treatise on astronomy, which was only an abridged extract of the works of Ptolemy; and likewise wrote on sun-dials, and gave a description of the astrolabe. The Jew Meshala, whose treatise on the elements was published at Nuremberg in 1549, also lived in the time of Almansor or Almamon.

Albategnius.

The most celebrated of the Arabian astronomers was Albategnius, or Muhammed Ben Geber Albatani, so called from Batan, a city of Mesopotamia, where he was born. He was a prince of Syria, and resided at Aracte or Racha, in Mesopotamia; but many of his observations were made at Antioch. Having studied the *Syntax* of Ptolemy, and made himself acquainted with the methods practised by the Greek astronomers, he began to observe, and soon found that the places assigned to many of the stars in Ptolemy's tables were considerably different from their actual situations, in consequence of the error which that great astronomer had committed with regard to the precession of the equinoxes. Albategnius measured the rate of the precession with greater accuracy than had been done by Ptolemy; and he had still better success in his attempt to determine the eccentricity of the solar orbit, his value of which differs extremely little from that which results from modern observations. In assigning the length of the year, however, he fell into an error of more than two minutes; but this proceeded, as has been shown by Dr Halley, from too great confidence in the observations of Ptolemy. Albategnius also remarked that the place of the sun's apogee is not immovable, as former astronomers had supposed, but that it advances at a slow rate, according to the order of the signs,—a discovery which has been confirmed by the theory of gravitation. A new set of astronomical tables, more accurate than those of Ptolemy, likewise resulted from the indefatigable labours of Albategnius; and his observations, important in themselves, are doubly interesting on account that they form a link of connection between those of the astronomers of Alexandria and of modern Europe. The works of Albategnius were published in 1537, under the title of *De Scientia Stellarum.*

Thebith Ben Korah.

Thebith Ben Korah, another Arabian, acquired celebrity by proposing an explanation of the motions of the stars, which, under the name of the "System of Trepidation," was eagerly received by the astronomers of the middle ages, and disfigured the tables of Alphonso, and even those of Copernicus. He ascribed to the *eighth* sphere, or that of the fixed stars, two motions; one the diurnal motion, the other that of trepidation, performed in small circles round the first points of Aries and Libra, and of

History.

which the radii were 4° 18′ 33″. He therefore supposed two ecliptics, one fixed in the ninth sphere, the other movable in the eighth. According to this construction, the motion of the stars is sometimes direct and sometimes retrograde.

The Arabians have been said to be not only the cultivators but the apostles of the sciences, on account of the activity with which they propagated them among all the nations subjected to their dominion. The Fatimite caliphs, who reigned in Egypt during two centuries, rivalled their predecessors the Ptolemies in the encouragement which they gave to astronomy. Under the caliph Hakem, who reigned from 996 to 1021 of our era, Ebn Jounis acquired a splendid reputation. He constructed a set of tables, and composed a sort of celestial history, in which he has recorded numerous observations of his own and of other astronomers belonging to the same country. This work, imperfectly known through some extracts, long excited the curiosity of astronomers, as it was supposed to contain observations tending to establish the acceleration of the mean motion of the moon. A manuscript copy of it, belonging to the university of Leyden, was, in 1804, transmitted to the French Institute, and translated by Professor Caussin. It contains 28 observations of eclipses from the year 829 to 1004; seven observations of the equinoxes; one of the summer solstice; one of the obliquity of the ecliptic made at Damascus, by which the value of that element is found to be 23° 35′; and likewise a portion of tables of the sun and moon, with some other matter illustrative of the state of astronomy among the Arabians. The observations which regard the acceleration of the mean lunar motion are two eclipses of the sun and one of the moon, observed by Ebn Jounis, near Cairo, in the years 977, 978, and 979, and they agree with theory in confirming the existence of that phenomenon.

Ebn Jounis.

The Saracen conquests in Spain were attended with the same happy results as in Egypt, and science flourished in that country while the rest of Europe was involved in the darkest shades of ignorance. Arzachel is supposed to be the author of the *Toledo Tables*, constructed about the year 1180, but which, on account of the established reputation of those of Albategnius, were never in great estimation. He made some changes in the dimensions which had been assigned by Hipparchus and Ptolemy to the solar orbit, and deserves the praise of having been an exact and attentive observer. Alhazen, who flourished in the same country about the same period, contributed to the progress of astronomy by a treatise on *Optics*, in which he clearly indicated the necessity of making an allowance for the celestial refraction in astronomical observations. His treatise contained a theory of reflection and refraction, an explanation of the cause of the twilight, and of the magnitude of the horizontal moon. Averroes, a physician of Cordova, made an abridgement of the Almagest in the twelfth century, and Almansor found the obliquity of the ecliptic to be 23° 33′ 30″, which proves that practical astronomy had now attained to a tolerable degree of exactness.

Arzachel.

Alhazen.

Averroes.

If we inquire what effect the labours of the Arabians and their disciples had on the progress of astronomy, we shall find that their services were confined entirely to the practical part. In point of theory they did absolutely nothing. They admitted all the hypotheses of Ptolemy without the slightest alteration, even with timid and superstitious respect, and did not advance a single step towards the discovery of the solar system. But with regard to instruments and methods of calculation, their improvements were numerous and important. They constructed instruments on a larger scale, and divided them with greater care; and, even from the time of Almamon, we remark among them new and more exact determinations of the obliquity of the ecliptic, of the positions of some stars, of the precession, of the length of the year, and of the eccentricity of the sun's orbit. To these fundamental points they added numerous observations of eclipses and conjunctions; they industriously sought out and corrected the errors of Ptolemy's tables; they perceived the necessity of marking the instant of each phenomenon with greater care; and their determinations of the commencement and end of eclipses are in general accompanied with the altitude of a star, which afforded them the means of calculating the hour, angle, and the true time. In cases where less precision was wanted, they made use of their clepsydræ and solar dials, to the construction of which they paid particular attention. Trigonometry derived signal advantages from their constant care to facilitate the calculations of spherical astronomy. Albategnius substituted the sines for the chords,—a most important improvement, the idea of which was probably suggested to him by the Analemma of Ptolemy. By this happy substitution the solution of all rectangular spherical triangles was reduced to four general formulæ, of which the Greeks had the equivalent in a much less commodious form. The same astronomer also appears to have invented a very remarkable rule for the oblique-angled triangles, perfectly identical with one of the four general formulæ now in use. Ebn Jounis, and his contemporary Aboul Wefa, were acquainted with the tangents and secants, and employed them very dexterously in reducing complicated binomial expressions to a single and simpler term. They also employed subsidiary arcs and other artifices in the calculus of the sines, in order to facilitate the labour of computation. These substitutions are now common; but they remained long unknown in Europe; and 700 years after they were employed by the Arabians, we first meet with some examples of their use in the writings of Thomas Simpson.

History.

The zeal of the Arabians for astronomical observations was communicated by them to the Persians and Tartars. About the year 1072, Omar Cheyam determined the length of the tropical year, and introduced the calendar which has ever since been used in Persia. Holegu-Ilecou-Khan, who conquered that country about the year 1264, caused an observatory to be built at Maragha, near Tauris, where he assembled the most celebrated astronomers who could be found within his dominions, and employed them in forming new astronomical tables. This work was directed by the famous Nassireddin, and brought to a conclusion in the year 1269. With the exception of some trifling corrections of the mean motions, the whole of these tables are copied from Ptolemy.

Holegu-Ilecou-Khan, died 1269.

Ulugh Beigh, a Tartar prince, and grandson of the great Tamerlane, not only encouraged the study of astronomy, but was himself a diligent and successful observer. At Samarcand, the capital of his dominions, he established an academy of astronomers, and caused the most magnificent instruments to be constructed for their use. By means of a gnomon 180 feet in height, he determined the obliquity of the ecliptic to be 23° 30′ 20″, the precession of the equinoxes at 1° in 70 years, and obtained elements for the construction of tables which have been found to be scarcely inferior in accuracy to those of Tycho Brahé. The ancient astronomy had produced only one catalogue of the fixed stars, that of Hipparchus. Ulugh Beigh has the honour of having formed a second, after an interval of sixteen centuries. This learned and munificent prince, whose virtue and talents deserved the esteem of mankind, was assassinated by his own son in the 58th year of his age.

Ulugh Beigh, died 1449

Revival of Astronomy in Europe.

After the death of Ulugh Beigh, astronomy received no farther accessions in the east. But the seeds of knowledge had now begun to take root in a more propitious soil, and Europe, destined to carry the development of the human energies to its fullest extent, began to awake from the lethargy in which it had continued during so many ages. The first dawnings of returning day appeared in Spain. In spite of the horror inspired by the Moslem religion, the Christians began to perceive and acknowledge the superiority and utility of the science of the Moors; and the schools of Cordova became the resort of all those whom curiosity, or love of knowledge, induced to seek abroad for that information which could not be obtained in their own countries. Geber, afterwards Pope Silvester II., acquired the knowledge of arithmetic from that source; and John of Halifax, better known by the name of Sacrobosco, after having studied some time in Spain, made an abridgement of the Almagest, which was long famous under the title of a *Treatise of the Sphere*.

Frederick II.

The emperor Frederick II. is no less celebrated for his protection of the sciences, than for the continual struggles in which he was involved with the popes. He founded the university of Naples, and caused Latin translations to be made of the works of Aristotle and the Almagest of Ptolemy. About the same time astronomy was zealously encouraged and cultivated by Alphonso X., king of Castile. This monarch, whose liberal mind seems to have been far superior to the age in which he lived, formed a college or lyceum at Toledo, the capital of his dominions, whither he assembled the most eminent astronomers that could be found, whether Christians, Moors, or Jews, and engaged them in the task of correcting the errors of the ancient tables. From their united labours were produced the *Alphonsine Tables*, which obtained great celebrity, and were, in some respects, superior in accuracy to any which had preceded them. They are supposed to have been chiefly the work of the Rabbi Isaac Aben Sid, surnamed Hazan, inspector of the synagogue of Toledo. They are said to have cost the king 40,000 ducats,—a sum certainly far exceeding their real value, which is confined to the correction of some epochs, and a more accurate determination of the sun's motions and the length of the year. The same century gave birth to several other individuals distinguished by their attachment to the sciences. Campanus of Nivari translated Euclid, and left a treatise on the sphere. Vitello, a native of Poland, composed a treatise on optics, in ten books; and Albert, bishop of Ratisbon, whom his contemporaries styled the *great*, was the author of some works on arithmetic, geometry, astronomy, and mechanics. But the greatest luminary of that age was Roger Bacon, a Franciscan friar, whose numerous works contain many indications of a powerful and inventive genius. He made many important discoveries in optics; but his knowledge of natural philosophy and chemistry, uncommon in those days, had nearly proved fatal to him; for he was suspected of necromancy, and thrown into a dungeon, from which he did not escape till he had satisfied his superiors and the pope that he had never held unlawful intercourse with the devil. He composed a work on the utility of astrology, the places of the stars, and the aspects of the moon; and he had the merit of perceiving the necessity of reforming the calendar.

Alphonso X., died 1284.

Roger Bacon, born 1214, died 1294.

urbach, born 1423, died 1461.

The fourteenth century produced no astronomer from whose labours the science gained any accessions. George Purbach, or Beurbach, so named from a small town in Austria, where he was born in 1423, obtained great celebrity as a professor. He studied at Vienna, and after giving proofs of distinguished talents, he travelled into Italy, where he was favourably received by the cardinal of Cusa, who himself cultivated astronomy. On his return to Vienna he undertook a translation of the Almagest; and although ignorant both of Greek and Arabic, his perfect acquaintance with the subject enabled him to correct many errors which had been introduced through the carelessness or ignorance of former translators. He published a table of sines for every ten minutes to a radius of 6,000,000 parts, which was afterwards extended by his scholar Regiomontanus to every minute of the quadrant. The most celebrated of his works is his *Theoricæ Novæ Planetarum*, which was published in 1460. He constructed a celestial globe, on which was represented the motion of the stars in longitude from the time of Ptolemy to the year 1450. He also measured the obliquity of the ecliptic, and is considered as the inventor of decimal arithmetic. He died in 1461, having only reached his 38th year, with the reputation of being, at that time, the first astronomer in Europe.

Regiomontanus, born 1436, died 1475.

Purbach had the good fortune to form a disciple who executed many of the plans which had been interrupted by his premature death. This was the celebrated John Muller of Königsberg, better known by the name of Regiomontanus. Attracted in his youth to Vienna by the great reputation of Purbach, he continued to study there during ten years, and on the death of his master repaired to Rome for the purpose of acquiring the Greek language, and of making himself, through it, acquainted with the Almagest. At Rome he continued his observations, and translated into Latin the works of Ptolemy, the *Conics* of Apollonius, and some other treatises of ancient science. In 1471 he retired to Nuremberg, where, with the aid of Bernard Walther, a wealthy burgess, he founded an observatory, and furnished it with excellent instruments, principally of his own invention, by means of which he was enabled to detect many errors in the ancient tables. On the invitation of Pope Sixtus IV., who wished to reform the calendar, he again repaired to Rome; but after a few months' abode there he died suddenly, according to some accounts, of the plague, according to others, through the effects of poison administered to him by the sons of George of Trebizond, who adopted this execrable method of revenging the exposure which he had made of their father's errors in the translation of the Almagest. Regiomontanus was a learned and skilful man, but the great expectations which his early labours gave of future services to astronomy were disappointed by his untimely death. He paid great attention to trigonometrical calculation; and, although he did not reach the point which had been attained by the Arabians, he had the merit of introducing some useful theorems which till then were entirely unknown in Europe. His genius, however, did not enable him to rise above the prejudices of his age, for he was an astrologer as well as an astronomer, and is said to have most lamented the errors of the Alphonsine Tables on account of the uncertainty which they occasioned in the calculation of genitures or horoscopes.

Walther, born 143[illegible], died 150[illegible].

After the death of Regiomontanus, Walther continued to observe at Nuremberg during thirty years. His observations were collected by order of the senate of Nuremberg, and published by Schöner in 1544, a second time by Snellius, and, lastly, along with those of Tycho Brahé. In 1484 Walther began to make use of clocks, then a recent invention, to measure time in celestial observations. He was also the first who employed the planet Venus as a term of comparison for determining the longitudes of the stars.

Nuremberg had the honour of producing another astro-

History.

Werner, born 1468.

nomer of some celebrity. John Werner was the first who explained the method which was afterwards brought into general use by Maskelyne, of finding the longitude at sea, by observing the distance between a fixed star and the moon. He published some mathematical and geographical treatises, and made a number of observations to determine the obliquity of the ecliptic and the precession of the equinoxes.

Overthrow of the Ptolemaic system.

We are now come down to a period in the history of astronomy when the science was destined to undergo a total renovation, and the system which had been so laboriously established by Ptolemy, and blindly followed as an article of religious belief by Arabs, Persians, Tartars, and Europeans, during so many centuries, was about to be exploded for ever. In proportion as the observations became more numerous and accurate, the difficulty of representing them by the Ptolemaic system became greater; and astronomers were obliged to have recourse to the most violent and improbable suppositions in order to explain the phenomena, and, in the language of Ptolemy, *save* the appearances. We have mentioned that Pythagoras and his disciples entertained an idea very different from that which commonly prevailed, and supposed the sun to be the immovable centre of the celestial motions. It appears, however, from Aristotle, that this opinion was not founded on any analysis of the phenomena, but on certain metaphysical notions respecting the comparative dignity of the several elements. For example, fire, being a nobler substance than earth, ought to occupy the centre or place of honour. But such arguments could have little weight except in the schools, and accordingly were rejected by Ptolemy as too absurd to require a serious refutation. In order to give any probability to the Pythagorean doctrine, it was necessary to explain the succession of the seasons and the precession of the equinoxes on the hypothesis of the annual revolution of the earth about the sun; to show how the unequal motions of the planets in concentric orbits would give rise to the phenomena of the stations and retrogradations; to account, in short, for all the appearances, and point out their coherence and mutual connection. All this was effected by Copernicus, who had thereby the glory of first making known the true system of the universe, and of leading the way in that career of astronomical discovery in which the genius of the human race has gained its noblest trophies.

Copernicus, born 1472, died 1543.

Nicholas Copernicus was born at Thorn, a city of Prussia, on the confines of Poland, according to Junctinus on the 19th of January 1472, and according to others on the 19th February 1473. From his earliest years he displayed a great fondness and aptitude for mathematical studies, and pursued them with corresponding success at the university of Cracow. Stimulated by the desire of acquiring a reputation equal to that of Regiomontanus, he set out for Italy at the age of 23 years, in order to study astronomy at Bologna under the celebrated Dominic Maria. He afterwards removed to Rome, where he employed himself in studying and teaching the mathematics, and where he made several astronomical observations about the year 1500. On his return to his native country he was made a canon of Ermeland by his uncle the bishop of Worms, and took up his residence at Frauenberg, a small Prussian town near the mouth of the Vistula, where he passed 36 years of his life in observing the heavens and meditating on the system of the world. In this retirement he composed his famous work entitled *Astronomia Restaurata, sive de Revolutionibus Orbium Cœlestium,* in which he explained the celestial motions in a manner as simple and connected as the system of Ptolemy was complicated and incoherent. The system which Copernicus adopted in this work is now so familiar to every one, that it is almost unnecessary to describe it. The heaven, composed of stars perfectly at rest, occupies the remotest bounds of space, then the orbit of Saturn, next Jupiter, Mars, the Earth accompanied by its moon, Venus, Mercury, and, lastly, the Sun immovable at the centre. By this arrangement the stations and retrogradations of the planets became simple mathematical corollaries, following from the differences of the radii of their orbits and their unequal motions. The diurnal rotation of the earth explained more simply and rationally the apparent daily revolution of the heavens; and the precession of the equinoxes was referred to a small variation in the inclination of the earth's axis to the plane of the ecliptic. But the simplicity of the system, and its consequent probability, were the only arguments which Copernicus was able to bring forward in proof of its reality. The motion of the earth can indeed never be made an object of sense; but after Richer's discovery of the diminution of gravity towards the equator, it was impossible to doubt longer of the existence of its rotatory motion; and when Roemer had measured the velocity of light, and Bradley observed the phenomena of the aberration, the evidences of its annual revolution were rendered equally convincing. Great, however, as were the merits of Copernicus, it must be acknowledged that he left his system in a very imperfect state. After the example of the ancients, he assumed as an axiom the uniform circular motion of the planets; and as the only motions which are observed are in a state of incessant variation, he was obliged, in order to save the inequalities, to suppose a different centre to each of his orbits. The sun was placed *within* the orbit of each of the planets, but not in the centre of any of them, consequently he had no other office to perform than to distribute light and heat; and, excluded from any influence on the system, he became as it were a stranger to all the motions. Yet notwithstanding these and other imperfections, the establishment of the doctrine of the earth's motion, with an evidence which dissipated the illusions of sense, was a great step towards the true knowledge of the planetary system; and when we consider the ignorance and prejudices of the age, and that Copernicus was moreover a priest, we cannot hesitate to admit his claim to a high rank among philosophers. But whether the actual services which he rendered to astronomy are commensurate with the great fame he has obtained, may admit of doubt. He revived an ancient opinion opposed to the prejudices and religious dogmas of his times, and fortified it with new and strong, though not absolutely convincing, proofs. It seldom happens, however, with regard to those sciences which ultimately appeal to experience, that general reasoning, even of the soundest kind, tends much to their real advancement; and there is little reason for thinking that astronomy would have been less perfect, or that any discoveries since made in it would have been retarded a single day, even if Copernicus had never lived. His great merit, like that of Lord Bacon, consists in the sound views which he took of nature, and in advancing so far before the general attainments of his age.

Fearing the opposition which was likely to arise from religious bigotry to opinions so much at variance with vulgar prejudice, Copernicus long delayed the publication of his great work; and it was only at the urgent request of his friends that he at last allowed it to be printed. He is said to have received the last sheet of it only on the day of his death. He was buried in the cathedral of Frauenberg, and his only epitaph consisted of some spheres cut out in relief on his tombstone.

History.

History.

The ideas of Copernicus soon spread over Germany, where astronomy was at that time diligently cultivated; but they do not seem to have met with general favour before the commencement of the seventeenth century. The art of observing was, however, gradually receiving improvement; instruments were constructed on better principles, and more accurately divided; and the methods of computation were rendered much less laborious. Nonius, or Nunez, a Portuguese, invented the ingenious method of subdividing the small divisions of instruments which still retains his name; Reinhold extended the table of tangents of Regiomontanus to every minute of the quadrant, reformed the tables of Copernicus, and composed many works of practical utility; but of the immediate successors of Copernicus, no one deserves to be more honourably mentioned than William IV., landgrave of Hesse. This prince built a magnificent observatory on the top of his palace at Cassel, which he furnished with excellent instruments of copper, and is said to have calculated himself the positions of no less than 400 stars. He was aided in the labours of the observatory by some astronomers of great merit whom his liberality drew to his court; among others, by Rothman, and Justus Byrgius, a distinguished artist, to whom Kepler has ascribed some idea of the logarithms.

Nonius, born 1497, died 1577.

William IV., died 1592.

Tycho Brahe, born 1546, died 1601.

Tycho Brahe, one of the best and most indefatigable observers of whom practical astronomy can boast, was born at Knudstorp, in Scania, the 13th of December 1546. His family was one of the most ancient and noble in Denmark; and his father, probably thinking that illustrious birth superseded the necessity of education, refused his consent to have his son instructed in Latin. Through the kindness of a maternal uncle, however, he was rescued from the state of barbarous ignorance to which he had been doomed by his parent; and, after having received the requisite preliminary instruction, he was sent to the university of Leipsic to study jurisprudence and scholastic philosophy. The tastes of the future astronomer were first excited by an eclipse of the sun which happened in 1560. Struck with astonishment at the accuracy of the prediction, he conceived a vehement desire to become acquainted with the principles of so certain a science, and exerted his utmost ingenuity to elude the obstacles which were interposed by his parents and governor to prevent him from acquiring the elementary notions of mathematics and astronomy. By placing the hinge of a common compass near his eye, he contrived to guess at the distances of the planets from the stars, and by this means, according to his own account, detected several errors in the Ephemerides of Stadius. By his persevering efforts he at last obtained the consent of his family to study according to his own inclinations; and from that moment he divided his time between the observation of the heavens, and chemical experiments. He visited the different cities of Germany where he hoped to meet with astronomers and skilful mechanicians, and was received with flattering attention by the landgrave of Hesse-Cassel, with whom he contracted an intimate friendship. On his return to Denmark he obtained from Frederick II. a grant of the small island of Huen, in the strait of Sunda, together with a pension and some presents, by means of which, and an expenditure of 100,000 crowns of his own patrimony, he was enabled to build the castle of Uraniburg, and procure a magnificent collection of the largest and most accurate instruments which could then be constructed. In this celebrated retreat he passed twenty-five years, actively employed in making observations, and attracting by his discoveries the attention of the learned throughout Europe. On the death of his protector Frederick he fell under the displeasure of the government, and a storm of persecution was raised against him, from causes which he has not explained, by a minister named Walckendorp, who, on this account, has been devoted by Lalande to the infamy and execration of all ages. He was deprived of his pension, compelled to leave the castle of Uraniburg, and to banish himself from Denmark. He retired first to Wandesburg, near Hamburg; he afterwards sought an asylum in Bohemia, and ultimately settled at Prague under the protection of the emperor Rudolph II. Here he resumed his observations, assisted by the illustrious Kepler and Longomontanus. The causes of his exile are involved in mystery; but to whatever it was owing, it turned out fortunate for the progress of astronomy. Had he remained in his island, his observations would not probably have fallen into the hands of Kepler, and the discovery of the laws of the planetary motions might have been deferred to another age. He died at Prague on the 24th of October 1601.

History

As an indefatigable and skilful observer, Tycho is justly considered as far superior to any astronomer who had preceded him since the revival of the science in Europe. His ample fortune gave him the means of procuring the best instruments which the age could produce; and by his ingenuity and persevering application, he was admirably qualified to employ them to the best advantage. He computed the first table of refractions, and if it extended only to 45°, the reason was, that the effects of refraction, at a higher altitude, were altogether insensible to his instruments. His solar tables were brought to so great a degree of exactness, that he affirms he could never detect an error in them exceeding a quarter of a minute; but there is reason to suspect some exaggeration in this statement, particularly as Cassini, a century after, with much better means, could scarcely answer for errors of a whole minute. He contributed greatly to the improvement of the lunar tables, and detected a considerable inequality in the moon's motion in longitude, to which he gave the name of the *Variation*, by which it has ever since been distinguished. He also discovered an equation in latitude similar to the evection which had been observed by Hipparchus, and fixed its amount with great accuracy. He remarked the fourth inequality of the moon in longitude, although he failed in his attempt to ascertain its amount, or assign its law. He represented the inequalities of the motions of the nodes, and in the inclination of the lunar orbit, by the motion of the pole of that orbit in a small circle round the pole of the ecliptic. He demonstrated that the region of the comets is far beyond the orbit of the moon, and determined the relative and absolute positions of 777 fixed stars with a scrupulous attention, which gave his catalogue an immense superiority over those of Hipparchus and Ulugh Beigh; and he left to his successors a regular series of observations on the planets, amassed for the purpose of establishing the truth of his own system, but of which Kepler made a better use by employing them to establish the system of Copernicus.

These are some of the important benefits which resulted to astronomy from the labours of Tycho. As a philosopher he ranks low. Alchemy and judicial astrology, in the reveries of which he was a firm believer, engrossed as much of his attention as astronomy. Yet his errors, or rather weaknesses, ought to be viewed with indulgence. He was seated, to use the simile of Bailly, on the confines of two ages; partaking of the darkness which preceded, and the light which came after him. He rejected the simple system of Copernicus, and, whether from participating in the religious scruples of his age, or from the

History.

ambition of appearing as the author of a new system, he restored to the earth its immobility, and placed it in the centre of the motions of the sun and moon. The Tychonic system was an unsuccessful attempt to reconcile the incongruous hypotheses of Ptolemy and Copernicus. It never enjoyed any real estimation; and its followers were only found among those who dreaded the anathemas of the church, or who, belonging to some university or religious corporation, were deprived of the liberty of expressing their real opinions.

Longomontanus, born 1562, died 1647.

Tycho was assisted in his observations at Huen, during eight years, by Longomontanus, who afterwards became professor of the higher mathematics at Copenhagen. This astronomer composed a large work, entitled *Astronomia Danica*, in which he deduced the elements of the different theories from the observations made at Uranibourg, and gave formulæ for computing the planetary motions, according to the three systems of Ptolemy, Copernicus, and Tycho.

Kepler, born 1571, died 1631.

The great mass of accurate observations accumulated by Tycho furnished the materials out of which his disciple Kepler may be said to have constructed the edifice of the world. This great man, the true founder of modern astronomy, was born at Wiel, in the kingdom of Wurtemberg, on the 27th of December 1571. He studied philosophy at Tubingen, and was instructed in mathematics and astronomy by Mœstlin, whose name deserves a place in the history of science, on account of his having been one of the first who had the courage to adopt and to teach the system of Copernicus. The philosophical mind of Kepler, disgusted with the improbabilities and absurdities of the ancient system, received with transport the novel doctrines explained by Mœstlin. The appointment of mathematician to the emperor, which he procured on the death of Stadius, confirmed him in the resolution which he had taken to devote himself to astronomical pursuits; and the energy of his character enabled him in a very short time to make himself thoroughly master of the different hypotheses and principal discoveries which had been made prior to his time. In the year 1596 he published a *Prodromus* of Dissertations on the properties and causes of the celestial orbits, which procured him the friendship of Tycho, and an invitation to take part in the observations and researches of that great astronomer at Prague. On the death of Tycho, which happened soon after, Kepler obtained possession of his invaluable collection of observations, and was charged with the task of completing and publishing the *Rudolphine Tables*.

During his short residence with Tycho, Kepler learned to check the fanciful suggestions of his brilliant imagination, and to draw his conclusions from observations alone, by rigorous and patient induction. The observations of the Danish astronomer had furnished him with the means of establishing with certainty the truth or inaccuracy of the various hypotheses which he successively imagined; and the diligence with which he laboured in comparing and calculating these observations during 20 years, was finally rewarded by some of the most important discoveries which had yet been made in astronomy. Deceived by an opinion which had been adopted by Copernicus, and had never been called in question by the ancients, that all the celestial motions are performed in circles, he long fruitlessly endeavoured to represent, by that hypothesis, the irregular motions of Mars; and after having computed with incredible labour the observations of seven oppositions of that planet, he at length succeeded in breaking down the barrier which had so long obstructed the progress of knowledge, and found that the motions could only be accurately represented by supposing the planet to move in an ellipse, having the sun in one of its foci. Having arrived at this important result, he next proceeded to consider the angular motion of the planet, and finding that it was not uniform in respect of any point situated within the orbit, he concluded that the uniform motion, till then universally received as an axiom, was a vain chimera, which had no existence in nature. He perceived, however, that the areas described by the radius vector of the planet, at its greatest and least distances, were equal in equal times; and subsequent observations enabled him to demonstrate that this equality extended to every point of the orbit. It was therefore discovered that Mars moves in an elliptic orbit, of which the sun occupies a focus, and in such a manner, that the area described by a line drawn from the centre of the planet to that of the sun is always proportional to the time of description. The same conclusions he found to be true in respect of the orbit of the earth; and therefore he could no longer hesitate to extend them by analogy to the other planets. These are two of the three general principles which are known by the name of the *Laws of Kepler*.

It was some years later before Kepler arrived at the knowledge of the analogy which subsists between the distances of the several planets from the sun, and the periods in which they complete their revolutions. To the discovery of this analogy he attached the greatest importance, and regarded all his other labours as incomplete without it. After having imagined numberless hypotheses, it at last occurred to him to compare the different powers of the numbers which express the distances and times of revolutions; and he found, to his infinite satisfaction, that the squares of the periodic times of the planets are always in the same proportion as the cubes of their mean distances from the sun. This is the third law of Kepler. He demonstrated it to be true of all the planets then known. It has been found to be equally true in regard to those which have been since discovered, and likewise to prevail in the systems of the satellites of Jupiter and Saturn. It is indeed, as can be shown mathematically, a necessary consequence of the law of gravitation, directly as the masses, and inversely as the squares of the distances.

By these brilliant discoveries, the solar system was reduced to that degree of beautiful simplicity which had been conceived by Copernicus, but from which that great astronomer had found himself constrained to depart. The sun could not occupy the common centre of the circular orbits, but his place is in the common focus of the elliptic orbits of all the planets; and it is to this focus that every motion is to be referred, and from which every distance is to be measured. The discovery of the elliptic motion, of the proportionality of the areas to the times, and the method of dividing an ellipse, by straight lines drawn from the focus to the periphery, into segments having a given ratio, formed the solution of a problem which had been the constant object of the labours of all astronomers from Ptolemy to Tycho, namely, to assign the place of a planet at any instant of time whatever. The tables which he computed for the elliptic motions form the model of those in present use. Some additions have been made in consequence of the perturbations, which the geometry of Kepler was inadequate to estimate, and which were only partially detected by the genius of Newton. It has been considered matter of surprise that Kepler did not think of extending the laws of the elliptic motion to the comets. Prepossessed with the idea that they never return after their passage to the sun, he imagined that it would only be a waste of time to attempt the calculation of the orbits of bodies which had so transitory an existence. He supposed

History.

the tail to be produced by the action of the solar rays, which, in traversing the body of the comet, continually carry off the most subtile particles, so that the whole mass must be ultimately annihilated by the successive detachment of the particles. He therefore neglected to study their motions, and left to others a share of the glory resulting from the discovery of the true paths of the celestial bodies.

The observations of eclipses had formed the principal object of the earliest astronomers, but it was Kepler who first showed the practical advantages which may be derived from them, by giving an example of the method of calculating a difference of meridians from an eclipse of the sun. The method extends to occultations of the stars, and is deservedly considered as the best we possess for determining geographical longitudes and correcting the tables. He composed a work on optics, replete with new and interesting views, and gave the first idea of the telescope with two convex glasses, which has since been advantageously substituted for that of Galileo. Prompt to seize every happy idea of his contemporaries, he perceived with delight the advantages which practical astronomy would derive from the new invention of the logarithms, and he immediately constructed a table, from which the logarithms of the natural numbers, sines, and tangents could be taken at once.

Kepler was not merely an observer and calculator; he inquired with great diligence into the physical causes of every phenomenon, and made a near approach to the discovery of that great principle which maintains and regulates the planetary motions. He possessed some very sound and accurate notions of the nature of gravity, but unfortunately conceived it to diminish simply in proportion to the distance, although he had demonstrated that the intensity of light is reciprocally proportional to the surface over which it is spread, or inversely as the square of the distance from the luminous body. In his famous work *De Stella Martis*, which contains the discovery of the laws of the planetary motions, he distinctly states that gravity is a corporeal affection, reciprocal between two bodies of the same kind, which tends, like the action of the magnet, to bring them together, so that when the earth attracts a stone, the stone at the same time attracts the earth, but by a force feebler in proportion as it contains a smaller quantity of matter. Further, if the moon and the earth were not retained in their respective orbits by an animal or other equipollent force, the earth would mount towards the moon one fifty-fourth part of the interval which separates them, and the moon would descend the fifty-three remaining parts, supposing each to have the same density. He likewise very clearly explains the cause of the tides in the following passage. "If the earth ceased to attract its waters, the whole sea would mount up and unite itself with the moon. The sphere of the attracting force of the moon extends even to the earth, and draws the waters towards the torrid zone, so that they rise to the point which has the moon in the zenith." It is not difficult to imagine how much these views must have contributed to the immortal discovery of Newton.

It is afflicting to consider how frequently the just rewards of true merit are usurped by charlatanism and pretension. While the fire-eaters and astrologers of Rudolph were basking in the sunshine of imperial favour, Kepler, from whose labours the sciences derived the most signal benefits, passed his life in extreme indigence. Born without fortune, the only revenue he possessed, and out of which he had to maintain a numerous family, arose from the precarious produce of his writings, and his pension of mathematician to the emperor,—a pension which, owing to the calamities of the times, was seldom duly paid. On this account he was obliged to prefer frequent solicitations, and undertake long journeys, whereby he lost his time, always precious to genius, and exhausted his mind in anxiety. He died on the 15th of November 1630, at Ratisbon, whither he had gone to solicit the arrears that were due to him. In the present century a marble monument has been erected to his memory by an enlightened prince, Charles of Alberg. It contains his bust and the ellipse of Mars; a monument more glorious and more imperishable than brass or marble.

History.

Galileo, born 1564, died 1642.

Contemporary with Kepler was the illustrious Galileo, whose discoveries, being of a more popular nature, and far more striking and intelligible to the generality of mankind, had a much greater immediate effect on the opinions of the age, and in hastening the revolution which was soon about to change the whole face of physics and astronomy. Galileo-Galilei, a Florentine patrician, was born at Florence in the year 1564. He passed his youth at Venice, where he continued till he was appointed to a professor's chair at Padua. After a residence of eighteen years in that city, he was induced to remove to Pisa by Cosmo II., who assigned him a pension, and conferred on him the title of his first mathematician. While residing at Venice, he heard it reported that Metius, a Dutch optician, had discovered a certain combination of lenses, by means of which distant objects were approximated to the sight. This vague and scanty intelligence sufficed to excite the curiosity of Galileo, who immediately set about inquiring into the means whereby such an effect could be produced. His researches were attended with prompt success, and on the following day he had a telescope which magnified about three times. It was formed by the combination of two lenses, a plano-convex and plano-concave, fitted in a leaden tube. In a second trial he obtained one which magnified seven or eight times; and subsequent essays enabled him to increase the magnifying power to 32 times. On directing his telescope to the moon, he perceived numerous inequalities on her surface, the diversified appearances of which led him to conclude almost with certainty that the moon is an opaque body similar to the earth, and reflecting the light of the sun unequally, in consequence of her superficial asperities. The planet Venus exhibited phases perfectly similar to those of the moon. These phases had been formerly announced by Copernicus as a necessary consequence of his system; and the actual discovery of their existence made it impossible to doubt of the revolution of Venus round the sun. He detected the four satellites or moons of Jupiter, and, in honour of his patron, gave them the name of the *Medicean Stars*. The discovery of these little bodies circulating round the huge orb of Jupiter afforded him a strong analogical proof of the annual revolution of the earth, accompanied by its moon. He perceived spots on the disk of the sun, from the motions of which he concluded the rotation of that body about its axis in the space of 27 days. The singular appearances of Saturn were beheld by him with no less pleasure than astonishment. His telescope was not sufficiently powerful to separate the ring from the body of the planet; and to explain the appearances he supposed Saturn to be composed of three stars almost in contact with one another. These discoveries proved that the substances of the celestial bodies are similar to that of the earth, and demolished the Aristotelian doctrine of their divine essence and incorruptible nature. They enlarged the ideas of mankind respecting the planetary system, and furnished the most convincing arguments in favour of the doctrines of Copernicus.

The discoveries of Galileo excited the envy of his

History.

contemporaries, and stirred up against him a persecution which embittered the last days of his life. The motion of the earth, which he had proved so triumphantly, was considered contrary to many express declarations of Scripture; it was also considered as a heresy in the schools, where the doctrines of Aristotle were followed with implicit submission. In defending the Copernican system, Galileo had incurred the bitterest resentment, both of theologians and peripatetics. His great reputation, his title of professor and first mathematician, gave them reason to dread that the new doctrines, recommended by such an advocate, would spread too rapidly, and finally overthrow the altars of Aristotle. They therefore combined to check their progress, and to procure the ruin of Galileo by injurious representatives to the Grand Duke and the court of Rome. Soon after his first telescopic discoveries he was cited to appear before the Inquisition, and a promise extorted from him that he would never, either by word or writing, support the opinion of the motion of the earth. But in a great mind the love of truth is the most imperious of all passions, and cannot be restrained by the frowns of despotism, or the persecution of a fanatical tribunal. The evidences of the motion of the earth burst forth from every point of the heavens; and Galileo, in his celebrated *Dialogues* on the system of the world, exposed them in so clear and forcible a manner, that, although he appeared to put them forth for the purpose of refuting them, it was not difficult to perceive that he regarded them as complete and indubitable. For this relapse into heresy he was again brought before the tribunal of the Inquisition, and, in the seventieth year of his age, condemned formally to retract and abjure the doctrine of the earth's motion, and to be imprisoned during the pleasure of the Inquisition. This scandalous proceeding has called forth the indignant reprobation of every lover of truth and freedom. "What a spectacle," exclaims Bailly, "an old man, whose hairs were blanched with study, watchings, and benefits to mankind, on his knees before the sacred Scriptures, abjuring the truth in the eyes of Italy, which he had enlightened, in opposition to the testimony of his conscience, and in spite of the manifestations given by nature through all her works."

The sentence passed on Galileo was not inflicted with great severity. At the end of a year the Grand Duke had the influence to procure his release from prison; but he was prohibited from returning to Florence, and obliged to confine himself to the Tuscan territory. He retired to the village of Arcetri, where he resumed his observations, and shortly afterwards discovered the libration of the moon. The satellites of Jupiter continued also to engage his attention, and he commenced a table of their motions, and pointed out the method of determining the longitude by means of their eclipses. The states of Holland, aware of the great benefit of his researches to commerce and navigation, sent two astronomers, Hortensius and Blaeu, to present him with a gold chain, and encourage him to persevere in his useful labours. A short time after receiving this honourable mark of esteem from a foreign country, Galileo suddenly became blind; and the task of forming the tables of the satellites was reserved for Cassini. He survived this misfortune only a few years, and expired in 1642, in the seventy-eighth year of his age.

Science is indebted to Galileo for two other discoveries of a different kind, less brilliant perhaps, but of far greater importance than those which we have yet enumerated. These are the isochronism of the vibrations of the pendulum, and the law of the acceleration of falling bodies. His telescopic discoveries could not have remained long unknown; in fact, with the exception of those of the phases of Venus, and of the triple form of Saturn, they were all fiercely disputed, even during his own lifetime. It is now universally admitted that he was the first who discovered the satellites of Jupiter, and the spots of the sun; but the very circumstance of other claimants to these discoveries having arisen, proves that they were within the reach of ordinary attention. No one ever thought of disputing with Kepler the discovery of the laws of the planetary motions. Those of Galileo required only eyes, and may be regarded as following of course from the discovery of the telescope; but his persecution, his condemnation, and his being compelled to retract and abjure a doctrine of which he had given the physical proof, inspire a hallowed interest in his history, and contributed much to the great reputation which he acquired throughout Europe.

Logarithms invented, 1614.

While astronomy was making these rapid advances in the hands of Kepler and Galileo, an event occurred in Scotland which contributed, though less directly, no less powerfully, to the acceleration of its progress. This was the invention of the logarithms by Lord Napier, baron of Merchiston; "an admirable artifice," says Laplace, "which, by reducing to a few days the labour of many months, doubles the life of the astronomer, and spares him the errors and disgust inseparable from long calculations; an invention of which the human mind has the more reason to be proud, inasmuch as it was derived exclusively from its own resources." It may be added, that without this, or some equivalent artifice, the computations rendered necessary by more correct observations would far exceed the limits of human patience or industry, and astronomy could never have acquired that precision and accuracy by which it is now distinguished above all the other branches of human knowledge.

Labours of different astronomers.

The same epoch presents to us a great number of excellent observers, who, although they did not produce any revolution in the state of astronomy, still rendered it useful service. Scheiner is celebrated for his observations on the solar spots, and his disputes with Galileo. John Bayer of Augsburg published a description of the constellations, accompanied by maps, in which the stars are marked by a Greek letter; a simple idea, which has been universally adopted. Lansberg, a Flemish mathematician, published in 1632 a set of astronomical tables, which, though filled with inaccuracies, rendered good service to science by apprizing Horrox of the transit of Venus over the sun's disk, which that young astronomer and his friend Crabtree had the satisfaction of observing on the 24th of November 1639. They were the first who ever witnessed that interesting but rare phenomenon. Snellius is celebrated for his measure of the earth. Gassendi, who had the merit, along with Descartes, of hastening the downfall of the Aristotelian philosophy in France, made some useful observations, particularly one of a transit of Mercury in 1631. His works, which fill six folio volumes, abound with curious and useful researches. Riccioli, a Jesuit, born at Ferrara in 1598, contributed to the progress of astronomy, not so much by his own discoveries, as by collecting and rendering an account of those of others. He rejected the system of Copernicus, and was more zealous in maintaining the doctrines of the church than in investigating nature; but his works form a vast repertory of useful information. His *Novum Almagestum* is a collection of the observations, opinions, and physical explanations of the phenomena, together with all the methods of computation then known. He was assisted in his labours by Grimaldi, who discovered the inflection of light, and gave the names to the principal spots of the moon which are now used by astronomers.

History.

Hevelius, born 1611. died 1687.

The most accurate observations that were ever made prior to the adaptation of the telescope to astronomical instruments were those of Hevelius, a rich citizen of Dantzic, who devoted his life and a large fortune to the service of astronomy. Having fitted up an observatory, and furnished it with the best instruments which could be procured, he commenced a course of observations, which he followed assiduously upwards of forty years. In his *Selenographia* he has given an accurate description of the face and spots of the moon, accompanied with excellent delineations of her appearance in her different phases and librations. The idea of making drawings of the different phases of the moon had previously occurred to Gassendi and Peiresc, but they had not been able to execute the project; indeed the difficulty attending it was such, that it occupied Hevelius, who was an excellent draughtsman, as well as observer, during a great number of years. Hevelius made an immense number of researches on comets; and finding that the observations could not be represented by rectilinear or circular orbits, he supposed them to move in parabolas. During a temporary absence from Dantzic, this indefatigable astronomer had the misfortune to lose, in a great fire which occurred in the city, his observatory, instruments, manuscripts, and almost the entire edition of the second volume of his *Machina Cœlestis*, which contained the results of his long labours and numerous observations. He was now in his old age, but his zeal did not give way under the terrible calamity. He patiently recommenced all his calculations, reconstructed tables of the sun, and prepared for publication his *Firmamentum Sobiescianum*, or celestial chart, which did not appear till after his death. Towards the latter part of his life, the use of telescopic sights began to be generally adopted. Hevelius, however, resisted the innovation, and continued to employ plain sights. This preference given to the ancient method by so skilful an observer induced Dr Halley to visit him at Dantzic, for the purpose of ascertaining, by a comparison of observations made at the same time and place, which of the two methods gave the most correct results. Dr Halley observed with the telescope, and Hevelius with his own instruments; but such was the dexterity he had acquired through long practice, that the difference of their observations seldom amounted to more than a few seconds, and in no case to so much as a minute. Notwithstanding this agreement, it is to be regretted that Hevelius did not adopt the new method; for, on account of the greater precision given to instruments by the use of the telescope, his observations, which were made without it, cannot now be admitted in the construction of tables, and consequently are for the most part useless to astronomy.

Huygens, born 1629, died 1695.

Few individuals have rendered more important services to science than Huygens. Born at the Hague in 1629, he studied geometry under Schooten, the commentator of Descartes, and gave early proofs of proficiency in that science by a treatise on the quadrature of the conic sections. Having passed into France, he studied law at the university of Angers; but his principal attention was directed to the physical sciences, particularly to optics. He employed himself in grinding and polishing lenses; and constructed a telescope of ten feet, with which he discovered one of the satellites of Saturn. His application of the pendulum to clocks deserves to be considered as one of the best gifts which genius has ever conferred on science. He seems to have conceived the idea of this application in 1656; and he presented the first description of the pendulum clock to the states of Holland in 1657. He endeavoured to make this invention subservient to the problem of the longitudes; and if his efforts were not attended with the desired success, it may be said, that without another invention, in which also he had a principal share, that of the spiral spring, the object would never have been accomplished so nearly as it was a hundred years later. By means of his excellent telescopes he discovered that the extraordinary appearance exhibited by Saturn was occasioned by a ring surrounding the body of the planet, and inclined to the ecliptic in an angle which he estimated at 21°. He published his observations on this planet in a work entitled *Systema Saturnium*, which still shows some traces of that species of reasoning from final causes which so greatly disfigures the writings of Kepler. For example, on discovering the satellite, he conceived that as the number of satellites now equalled the number of planets, it was in vain to look for more, the equality being necessary to the harmony of the system. He lived, however, to witness the discovery of four more satellites belonging to the same planet. Huygens was invited to settle in France by Colbert, the patriotic minister of Louis XIV., who assigned him a pension and a seat in the academy of sciences. He continued in that country till the revocation of the edict of Nantz in 1681, when he resigned his pension and retired to Holland. After this he contributed several papers to the *Philosophical Transactions*, and in 1690 published a treatise on light and gravitation. Geometry, mechanics, and optics, are indebted to the genius of Huygens for many important discoveries. His theorems on central forces, his researches on the doctrine of probabilities and continued fractions, and his theory of involutes and evolutes, raise him to the highest rank among the mathematicians of his age. He died on the 8th of June 1695, at the age of 66 years.

Telescopes applied to quadrants, 1667.

The application of telescopes and micrometers to graduated instruments forms an important epoch in the history of astronomy. This happy improvement was first brought into use by Picard in 1667. Morin, indeed, had applied a telescope to the quadrant so early as 1634, and *perceived* the stars in full day in 1635. In 1669 Picard began to observe the stars on the meridian in the daytime, with a quadrant, to which, in concert with Azout, he had applied an astronomical telescope having cross wires in its focus. Huygens invented the plate micrometer in 1650; Malvasia that with the fixed wires in 1662; and Azout that with the movable wire in 1666. (See Delambre, *Astronomie du Moyen Age*, p. 618. Note by Bouvard.) It is principally to the happy discoveries and ingenious inventions just referred to, and the fine application of the pendulum to clocks by Huygens in 1656, that we must attribute the rapid progress since made in practical astronomy, and the extreme precision of modern observations. Picard was also the first who introduced the modern method of determining the right ascensions of the stars, by observing their meridional passages, and employed the pendulum for that purpose. He likewise introduced the method of corresponding altitudes, and is entitled to be regarded as the founder of modern astronomy in France.

Roemer, the friend and pupil of Picard, discovered the progressive motion of light in 1675, and measured its velocity by means of the eclipses of Jupiter's satellites. He was the first who erected a transit instrument, which gave a new accuracy to observations of right ascension.

Dominic Cassini, born 1625 died 1712.

The Royal Observatory of Paris was completed in 1670, and its direction intrusted to Dominic Cassini. This celebrated astronomer was born at Perinaldo, in the county of Nice, and educated in a college of the Jesuits at Genoa. He acquired an early passion for astronomical observations; and in 1644 was invited to Bologna by the marquis Malvasia, where, in 1650, he succeeded Cavalleri

History.

as professor of astronomy. In this situation he continued till 1669, when he went to Paris on the invitation of Louis XIV. He was naturalized in France in 1673, and continued in the charge of the observatory till his death, which happened in 1712.

Cassini enriched astronomy with a great number of curious observations and discoveries. He determined the motions of Jupiter's satellites from observations of their eclipses, and constructed tables of them, which were found to be remarkably exact. He observed that the ring of Saturn is double, and discovered four of the satellites of that planet. He also determined the rotation of Jupiter and Mars, and made a number of observations on Venus with the same view. He observed the zodiacal light, and made a near approximation to the parallax of the sun. We also owe to him the first table of refractions, calculated on correct principles; and a complete theory of the libration of the moon. Galileo had only observed the libration in latitude; Hevelius explained the libration in longitude, by supposing that the moon always presents the same face to the centre of her orbit, of which the earth occupies a focus. Cassini made the important remark, that the axis of rotation of the moon is inclined to the ecliptic, and that its nodes coincide with those of the lunar orbit, so that the poles of the orbit, ecliptic, and equator of the moon, are on the same circle of latitude, the pole of the ecliptic being situated between the other two. The greater number of these discoveries are, however, only of secondary importance; and it must be confessed that Cassini took no part in the great and permanent improvements which astronomy received in that age. He has, nevertheless, obtained an extraordinary reputation. Lalande remarks, that in his hands astronomy underwent the most signal revolutions, and that his name is, in France, almost synonymous with that of creator of the science. Delambre has, however, taken a different and far more accurate view of the real services of Cassini. "The revolution in Astronomy," this judicious critic observes, "was brought about by Copernicus, by the laws of Kepler, by the pendulum of Huygens, the micrometers of Azout and Picard, by the sectors and mural of Picard, and his method of corresponding altitudes, by the transit instruments of Roemer; and Cassini appears to us an entire stranger to all these innovations. He followed another route; he devoted a long life to painful observations, which at last deprived him of sight. Let us not refuse him the praise which he has so well merited, but let us reserve a place in our esteem for labours less brilliant perhaps, but of greater and more permanent utility, and which evince at least equal talent and sagacity."

Maraldi.

Cassini was assisted in his observations by his nephew, James Philip Maraldi, who determined the regression of the nodes, and the progressive motion of the apsides of the orbit of Jupiter. This astronomer also corrected the theory of Mars, and observed the sun's parallax. He rejected the hypothesis of the progressive motion of light, as being insufficient to explain the inequalities of Jupiter's satellites; and he conceived the design of forming a new catalogue of the stars, which, however, was never executed. He died in 1729.

Progress of science in the 17th century.

There is no period in the history of mankind so distinguished by great and important discoveries, or so remarkable for the rapid development of the human intellect, as the seventeenth century. We have already noticed the invention of the pendulum, and its application to regulate the motion of time-keepers; of the telescope, and some of the phenomena of the new worlds it has exposed to view; of the logarithms, by which computations are so much abridged; and of the mechanical contrivances for measuring minute angles in the heavens. The same century witnessed the application of algebra to geometry, the discovery of the laws of the planetary motions, of the infinitesimal calculus, the acceleration of falling bodies, the sublime theory of central forces, and the great principle of gravitation which connects the celestial orbs, and regulates the motions which it had been the business of the astronomer to observe since the earliest ages of the world. The different steps which conducted to this important discovery, and the immediate consequences deduced from it by its immortal author, are so fully developed in the admirable Dissertation on the Progress of the Physical Sciences, in this Encyclopædia, that it is unnecessary to enter into any detail respecting them here; we may only remark, that if observation has furnished the data for the discovery of the mechanical principle and primordial laws of the universe, the knowledge of these laws has been, in turn, of the most essential service to observation, by guiding and directing it to its most important objects. Many of the inequalities of the planetary motions, in consequence of their minuteness and the slowness with which they vary, could not have been detected by observation; others might perhaps have been perceived, but we should still have been ignorant whether their constant accumulation might not ultimately change the state of the system, and, by destroying all confidence in the tables, demolish the fabric which had been reared at such a vast expense of time and labour. But when these inequalities are detected by theory, and separated from the mean motions with which they were blended, it becomes an object of the highest interest to confirm their existence by the most delicate and accurate observations. Hence, a more refined practice has constantly followed every theoretical discovery. Besides, it is the perfection of theory, and not the mere knowledge of isolated facts, which gives astronomy its greatest value in the eyes of the philosopher. Numerous and important as its applications are, they have but a subordinate interest, in comparison of the knowledge of those general laws to which every particle of matter in the universe is subject, and by the discovery of which man has penetrated so deeply into the mysteries of nature.

Discoveries of Newton, born 1642, died 1727.

By the discovery of the law of gravity Newton laid the foundations of physical astronomy; and by the consequences which he deduced from that law, proceeded far in the erection of the superstructure. He showed that the motions of all the bodies of the planetary system are regulated by its influence; he determined the figure of the earth on the supposition of its homogeneity; he gave a theory of the tides, discovered the cause of the precession of the equinoxes, and determined some of the principal lunar inequalities and planetary perturbations. Many of his theories were left in an imperfect state; for it is not in matters of science that it is given to the same individual to invent and bring to perfection: their complete development required that several subsidiary sciences should be farther advanced; but it has been the triumph of his system, that every subsequent discovery has only tended to strengthen and confirm it. This bright ornament of the human genius was born on the 25th of December 1642, the day of the death of Galileo, and died on the 20th of March 1727, in the 85th year of his age.

Flamsteed, born 1646, died 1719.

While physical astronomy was undergoing a complete revolution in the hands of Newton, the practical part was receiving great improvement from Flamsteed, the first astronomer royal, who conducted the Greenwich Observatory. This celebrated institution, from which so many important discoveries have emanated, was erected under the reign of Charles II, in 1675. Flamsteed was appoint-

History.

ed to it in 1676, and continued with indefatigable zeal to discharge the duties of the office during the long period of 33 years. In the course of this time he made an immense number of excellent observations, the results of which are given in the *Historia Cœlestis*, the first edition of which was published in 1712, at the expense of Prince George of Denmark, the husband of Queen Anne. The second appeared in 1723, some time after the death of the author, in three volumes folio. The first volume contains the observations which he made, first at Derby, and afterwards at Greenwich, on the fixed stars, planets, comets, spots of the sun, and Jupiter's satellites. The second volume contains the transits of the planets and stars over the meridian, and the places of the planets deduced from these observations. The third contains an historical notice, in which he gives a description of the instruments used by Tycho and himself; catalogues of fixed stars by Ptolemy, Ulugh Beigh, Tycho, the landgrave of Hesse, and Hevelius; together with the British Catalogue, containing the places of 2884 stars. The labours of Flamsteed were, however, confined entirely to the practical part of astronomy. He made no improvements in theory; but he is entitled to the merit of having been the first who brought into common use the method of simultaneously observing the right ascension of the sun and a star, a method by means of which the determination of the positions of the stars is reduced to the observation of meridional transits and altitudes. He was likewise the first who explained the true principles of the equation of time; and he improved the lunar tables by introducing into them the annual equation which had been suggested by Horrox. The *Atlas Cœlestis*, another posthumous work of Flamsteed, was published in 1753.

Halley, born 1656, died 1742.

Flamsteed was succeeded in the observatory by Dr Halley, a philosopher whose inventive genius and indefatigable activity rendered him one of the brightest ornaments of his country. Halley was the son of a wealthy citizen of London, where he was born on the 8th of November 1656. From his earliest years he applied himself with ardour to the study of mathematics and astronomy; and having procured a few instruments, he began to make observations, by which he was led to remark the inaccuracy of the tables of Jupiter and Saturn. In his 19th year he published a direct and geometrical method of finding the eccentricities and aphelia of the orbits of the planets; and in the year following he undertook a voyage to St Helena, with a view to form a catalogue of the stars in the southern hemisphere. The station was unfortunately chosen, for, owing to the incessant rains and foggy atmosphere of that island, he was able to determine the places of only 360 stars in the course of a whole year. He had, however, the satisfaction of observing a transit of Mercury over the sun's disk, a phenomenon which suggested to him the important remark, that the transits of the inferior planets might be advantageously employed in determining one of the most essential elements of the planetary system, viz. the parallax of the sun, and consequently the diameters of the orbits. The method has since been successfully employed in the case of Venus: the transits of Mercury, though much more frequent, are not so well adapted to the purpose. On his return from St Helena he was commissioned by the Royal Society to visit Hevelius at Dantzic, and determine, by a direct comparison of observations, the dispute which had arisen between that astronomer and Dr Hooke respecting the relative advantages of plain and telescopic sights. After this Halley for some time travelled on the Continent, and on his return to England devoted himself entirely to scientific pursuits. The fruits of his leisure soon began to appear in the multitude of treatises which he published from time to time in every department of the mathematical and physical sciences. The most important of those connected with astronomy was his *Synopsis Astronomiæ Cometicæ*,—a work abounding in profound and original views, and which, in respect of theory, formed perhaps the most remarkable accession to the science that had been made since the time of Kepler. In this work he revived an ancient opinion, that the comets belong to the solar system, and move in very eccentric orbits round the sun, returning after stated but long intervals. He also ventured to predict that the comet of 1681 would again return to its perihelion in 1759,—the first prediction of the kind that was verified. In 1720 Dr Halley was appointed to succeed Flamsteed in the Royal Observatory; and though now in the 64th year of his age, he undertook, with a view to improve the lunar theory, to observe the moon through a whole revolution of her nodes, erroneously supposing, that after such a revolution the errors of the tables would again appear in the same order. He was the first who, by a comparison of ancient and modern observations, remarked the acceleration of the mean motion of the moon, and thus called the attention of mathematicians to an important and curious phenomenon, the physical cause of which was at length detected by the powerful analysis of Laplace. He was also the first who pointed out the secular inequalities of Jupiter and Saturn, occasioned by their mutual perturbations,—a theory that formed the subject of several profound memoirs of Euler and Lagrange, and for the complete development of which astronomy is likewise indebted to Laplace. Besides these important discoveries in astronomy, the labours of Dr Halley also greatly contributed to the promotion of geometry and navigation. He undertook two long voyages, and traversed the Pacific Ocean to observe the deviations of the magnetic needle; and posterity will gratefully recollect that it was through his pressing solicitations that Newton consented to the publication of the *Principia*. In 1703 he succeeded Dr Wallis as professor of geometry at Oxford. He became secretary of the Royal Society in 1713, and died at Greenwich in 1742.

Bradley, born 1692, died 1762.

The discoveries of Bradley, who succeeded Halley as astronomer-royal, form a memorable epoch in the history of the science. This great astronomer was born at Sherborne in Gloucestershire in 1692, and acquired from his uncle, Mr Pound, an early taste for astronomical observation. He was destined for the church, and for some time held a curacy, which he resigned in 1721, on being appointed to succeed Keill as Savilian professor of astronomy at Oxford. His first essays indicated no extraordinary talent; but an opportunity having presented itself of engaging in more important researches, he embraced it with ardour; and by his sagacity and perseverance was conducted to two discoveries which have entirely changed the face of astronomy.

Discovery of the aberration of light.

A singular motion of the polar star had been observed by Picard, of which, however, that astronomer could neither assign the law nor give any satisfactory explanation. He only remarked that the inequality was annual, and amounted to about 40 seconds. Hooke, in 1674, a few years after the observations of Picard, imagined that he had discovered a parallax in some of the stars; and Flamsteed, following the ideas of Hooke, explained, by means of parallax, the minute changes of position which he had observed in Polaris and some circumpolar stars. Manfredi and Cassini demonstrated the error of Flamsteed, but were not more successful in their attempts to explain the motion in question. Samuel Molyneux conceived the idea of verifying all that had been said respecting the

History.

supposed parallaxes, and for this purpose commenced a series of observations at Kew, with an excellent 24 feet sector constructed by Graham. Bradley, who happened at that time to reside at Kew, took a part in these observations, the result of which was, that the remarks of Picard were confirmed beyond the possibility of doubt. It was, however, abundantly evident that the apparent motions alluded to were not connected in any manner with parallax; it therefore became an object of the greatest interest to determine their physical cause, and assign their law and period. The first idea that occurred was to inquire whether they arose from a change of position in the earth's axis; but this supposition was found to be inadequate to the explanation of the phenomena. Molyneux having been in the mean time appointed a lord of the admiralty, the observations were discontinued at Kew; they were, however, shortly after resumed by Bradley at Wanstead, with a smaller but more convenient instrument; and after they had been continued several years, it was found that the star (γ draconis) on which they were principally made, appeared to describe annually a small ellipse, the transverse axis of which amounted to 40″. This was an important determination; for the ellipse afforded the means of computing at all times the aberration of any star whatever, whether in longitude, latitude, declination, or right ascension. Bradley also pointed out the physical cause of the aberration, and demonstrated that it resulted from the combination of the motion of light with the annual motion of the earth. This capital discovery was made in 1728.

Discovery of the nutation of the terrestrial axis.

Bradley, anxious to verify his ingenious theory, continued his observations, and soon felt the difficulty that had so much embarrassed Picard. The places of the stars, calculated according to his formula for the aberration, could not be reconciled with the observations. The errors continued to augment during nine years, after which they went on diminishing during the nine years following. This inequality, of which the period, like that of the nodes of the moon, was 18 years, was readily explained by supposing a slight oscillation of the earth's axis, occasioned by the action of the moon on the protuberant parts surrounding the equator of the terrestrial spheroid. After assiduously observing its effects during twenty years, Bradley found that the phenomena could be accurately represented by giving the pole of the equator a retrograde motion about its mean place in an ellipse whose axes are 18″ and 16″, and completing its revolution in the period of 18 years. This result was communicated to the Royal Society in 1748. To these two grand discoveries of Bradley, the aberration and nutation, modern astronomy is wholly indebted for all its accuracy and precision; and, as Delambre remarks, they assure to their author a distinguished place, after Hipparchus and Kepler, above the astronomers of all ages and all countries.

Bradley was appointed astronomer royal in 1741, and from this time to the period of his death made an immense number of observations, which were presented by his heirs to the university of Oxford, on condition that they should forthwith be published. The first volume appeared only in 1798, edited by Dr Hornsby. The rest were committed to the care of the late Dr Abraham Robertson, and appeared in 1805. Dr Bradley was chosen a corresponding member of the Academy of Sciences in 1748. In 1752, twenty-four years after his great discovery of the aberration of light, he was admitted into the Royal Society. He died on the 13th of July 1762, in the 70th year of his age.

While England was deriving so much glory from the brilliant discoveries of Bradley, France produced a multitude of excellent astronomers, by whose successful labours every department of the science was signally promoted. Among these Lacaille is pre-eminently distinguished, both by the variety and importance of his observations, and the indefatigable zeal with which, during twenty-two years, he prosecuted the most laborious researches. He commenced his astronomical career in 1739, by assisting Cassini de Thury (grandson of the first Cassini) in the verification of the measurement of the meridian through France. In 1751 he undertook a voyage to the Cape of Good Hope, the primary objects of which were to determine the sun's parallax, by means of observations on the parallaxes of Mars and Venus, while similar observations were made in Europe; and to form a catalogue of the southern circumpolar stars. No undertaking for the benefit of science was ever more successfully executed. In the course of a single year, Lacaille, without assistance, observed upwards of ten thousand stars, situated between the tropic of Capricorn and the pole, and computed the places of 1942 of them; a labour which would scarcely be credited, if the details of his observations had not been published in the *Cœlum Australe Stelliferum*, a work which was given to the world in 1763. Our admiration of the rapid execution of this vast undertaking will be increased, when we consider, that during the same time he measured a degree of the meridian, and made numerous observations on the moon simultaneous with those of Lalande, who observed at Berlin, in order to determine the moon's parallax, by means of direct observations made at the extremities of a meridional arc of upwards of 85 degrees. Before his return to Europe, he visited the isles of France and Bourbon, where he measured the length of the pendulum, and made numerous remarks on the natural and civil history of those countries. Astronomy is likewise indebted to Lacaille for a table of refractions which he computed from a comparison of above 300 observations made at the Cape and at Paris. In 1757 he published his *Astronomiæ Fundamenta*, in which he gave rules and tables for computing the apparent motions of the stars, which continued to be employed till Lambert supplied the corrections depending on the nutation, and Delambre those depending on the aberration. To defray the expense attending the publication of this important work, which he distributed in presents to the different observatories and astronomers in Europe, he submitted to the drudgery of calculating ephemerides during ten years. Lacaille composed several elementary works for the use of the students in the college of Mazarin, where he occupied the chair of astronomy, and inserted a great number of memoirs in the volumes of the Academy of Sciences. This great astronomer, distinguished as much by the excellence of his moral qualities as his profound knowledge and indefatigable zeal, died suddenly in 1762.

Lacaille, born 1713, died 1762.

Cassini II. born 1677 died 1756.

The Royal Observatory of Paris continued under the direction of the family of Dominic Cassini during 120 years. James Cassini, the second of that name, is principally known by a work on the magnitude and figure of the earth, and his *Elements of Astronomy*. He seems not to have duly appreciated the new discoveries which were daily making around him. His *Elements*, published in 1740, contains no mention of the aberration; and he adopted the opinion that the earth is elongated instead of being flattened at the poles. His son, Cassini de Thury, was chiefly occupied with the meridian, and the geometrical survey of France. The last astronomer of the family, the Count de Cassini, was obliged to resign the observatory at the revolution.

Measurement of the earth.

The question of the figure of the earth furnished ample materials for the practical as well as the speculative as-

History.

tronomer during the last century. The results of the measurement of the meridian by Cassini were at variance with the theories of Newton and Huygens; and the Academy of Sciences resolved on making a decisive experiment by the actual measurement of the lengths of two degrees, one at the equator, and another in as high a latitude as could be reached. In the year 1735, three astronomers, Godin, Bouguer, and La Condamine, were commissioned by the French government to accomplish the first of these objects in Peru; and the year following, Maupertuis, Clairaut, Camus, and Lemonnier, went to Lapland to execute the second under the polar circle. Notwithstanding the greater difficulties they had to contend with, the first party were the most successful; but the result of both operations established the compression of the earth at the poles. Bouguer published the details of the Peruvian measurement in an admirable work on the *Figure of the Earth*, in which he has also inserted an account of a great number of experiments made by him in the same country to determine the length of the seconds' pendulum, and the effects of the attraction of mountains on the plumb-line. Bouguer is likewise the author of an excellent treatise on light. This accomplished mathematician and experimenter did not adopt the Newtonian theory of gravitation, but he was the last apostle of the Cartesian philosophy in the Academy of Sciences.

It would greatly exceed the limits of this article to give even an abridged account of the numerous observers who, about this period, contributed to the improvement of every department of practical astronomy. We must therefore content ourselves with merely noticing the names of some of the most distinguished, leaving the details of their labours to be given in the biographical articles interspersed throughout the work.

Delisle, born 1688, died 1768.

Delisle formed a school of astronomy in Russia, and has left a method of computing the heliocentric places of the sun's spots, and of Mercury and Venus in their transits over the sun's disk, and likewise of determining, by means of the stereographic projection, the directions of their path when they enter and leave the disk. Lemonnier introduced the discoveries of Bradley into his *Astronomical Institutions*, and was the instructor of Lacaille and Lalande. He published a *Histoire Céleste*, containing a collection of observations from 1666 to 1685, and a number of other works and memoirs connected with astronomy. He made an immense number of observations, but their accuracy is far inferior to those of Bradley. Wargentin, secretary of the Academy of Sciences of Stockholm, devoted the whole of his life to the correction of the tables of the satellites of Jupiter. The theory of the satellites was not then far advanced; but when theory failed him, he profited by the remarks of others and by his own reflections, and endeavoured by repeated trials to find empirical equations capable of conciliating the tables with the best observations. By confining himself almost exclusively to this subject, he acquired a high reputation, and was ranked among the first astronomers of an epoch which abounds in great names. His tables of the satellites have, on account of their superior accuracy, been employed in determining the masses, and other elements, which serve as the basis of the analytical theories.

Lemonnier, died 1799.

Wargentin, born 1717, died 1783.

Lalande, born 1732, died 1807.

One of the most celebrated astronomers of the last century was Lalande. He commenced his early career by a set of lunar observations at Berlin, undertaken simultaneously with those of Lacaille at the Cape, for the purpose of determining the moon's horizontal parallax. On his return to Paris he was received, though only twenty-one years of age, into the Academy of Sciences; and on the resignation of Delisle was appointed professor of astronomy in the college of France. By his extraordinary zeal, indefatigable activity, and the care which he took to have his name constantly before the public, Lalande soon became one of the most distinguished men of his day; but his reputation, acquired in a great measure from attention to subjects which had only an ephemeral interest, and not through any permanent or fundamental additions to science, has already begun to wane; and his works, many of which are of considerable utility, seem to have fallen into unmerited neglect. His character as an astronomer is fairly and impartially summed up by Delambre in the following terms:—"If Lalande did not renew the foundations of astronomical science, like Copernicus and Kepler,—if he did not, like Bradley, immortalize himself by two brilliant discoveries,—if he was not so learned and accurate a theorist as Mayer,—if he was not to the same degree as Lacaille an exact, expert, scrupulous, industrious, and indefatigable observer and calculator,—if he had not the constancy to attach himself, like Wargentin, to a single object, in order to become the first in a particular department,—and if, in all these respects, he was only an astronomer of the second rank,—he was the first of all as a professor. No one ever did more to propagate the knowledge and love of astronomy. It was his object to be useful and celebrated; and he succeeded, through his labours, his activity, his credit, and his solicitations: by means of a most extensive correspondence he incessantly laboured for the benefit of science: he even endeavoured to serve it after his death, by founding a medal, which the Academy of Sciences adjudges annually to the astronomer who has made the most interesting observation, or written the most useful memoir." (Delambre, *Astronomie du Moyen Age.*)

Maskelyne, born 1732, died 1811.

Bradley was succeeded in the Greenwich Observatory by Dr Bliss, who died in the course of a few years after his appointment. Dr Bliss was in turn succeeded by Dr Maskelyne, the late astronomer royal, under whose care the observatory maintained the high character which it acquired from the immortal labours of his illustrious predecessors. Dr Maskelyne began his astronomical career in 1761, when he was appointed to observe the transit of Venus at the island of St Helena, and endeavour to verify the existence of a small parallax of the star Sirius, which seemed to be indicated by the observations of Lacaille at the Cape. Unfortunately the state of the weather prevented him from observing the transit; and his observations on Sirius were abandoned in consequence of the discovery of a defect in the zenith sector which he had carried out with him for the purpose of making the observations in question. The main objects of his voyage were thus frustrated; but some indirect advantages resulted from it, which compensated in some measure for the disappointment. The attention of Ramsden was called to the sector, and a better method of constructing these instruments was devised. At St Helena he made several interesting observations on the tides, the variation of the compass, the moon's horary parallaxes, &c. In going out and returning home, he paid particular attention to the different methods of finding the longitude at sea, and practised that which depends on observations of the lunar distances from known stars, taken with a Hadley's sextant, or other reflecting instrument. He also composed a set of rules for the use of the seamen, which he published on his return, first in the *Philosophical Transactions*, and afterwards in the *British Mariner's Guide*. In the year 1765 he was appointed astronomer royal, and soon after recommended to the Board of Longitude the general adoption in the navy of the lunar method of finding the

History.

longitude, and proposed that tables for facilitating that method should be calculated and published in the *Nautical Almanac*. This recommendation was adopted, and the Nautical Almanac continued to be published under his superintendence during forty-eight successive years. He also published a set of tables requisite to be used with that long-celebrated ephemeris; and by these means contributed to bring nautical astronomy to its present state of precision. Dr Maskelyne was most assiduous in the discharge of his important duties as astronomer royal. On one occasion only did he consent to leave the observatory, viz. when at the request of the Royal Society he proceeded to Scotland for the purpose of determining, by experiments on Schehallien, the deflection of the plumb-line occasioned by the attraction of the mountain. The result of the observations made on this occasion furnished data for the determination of the mean density of the earth, which Dr Hutton, by a laborious process of calculation, found to be about five times greater than that of water. Dr Maskelyne had the credit to procure, at the expense of the Royal Society, the regular publication of his observations, by which he rendered a great service to all the astronomers of Europe. The lunar method of determining the longitude, the Nautical Almanac, the catalogue of 36 stars, and some improvements in the construction of instruments, are the principal benefits for which astronomy is indebted to Dr Maskelyne.

Herschel, born 1738, died 1822.

Sir William Herschel, born in Hanover in 1738, has rendered his name immortal by the discovery of a new planet without the orbit of Saturn, and thereby doubling the ancient boundaries of the solar system. Having settled in England, at Bath, he began to devote his leisure to the construction of telescopes and the polishing of reflecting mirrors. Endowed with equal skill and patience, he soon obtained instruments superior to any that had been known before, by means of which he was led to the most brilliant discoveries that have been made in the heavens since the time of Galileo. Being employed in making a review of the sky with a powerful telescope, he perceived, on the 13th of March 1781, near the feet of Gemini, a star of the fifth magnitude, having a disk perfectly well defined, and differing in appearance from the other stars which afforded the same quantity of light. On observing it with a telescope whose magnifying power was 932, he perceived its diameter was enlarged, while that of the stars underwent no change. These circumstances were sufficient to draw his attention to the star, and nothing more was requisite to enable him speedily to discover that it had a slow motion. He at first supposed it was a comet, and acquainted Dr Maskelyne with the discovery. The circumstance was soon made known at Paris; and it was gradually perceived, that as the distance of the star did not sensibly vary, it was necessary to regard it as a seventh planet. Herschel, in honour of his royal patron, gave it the name of the *Georgium Sidus;* but the mythological appellation of Uranus has prevailed. On the 11th of January 1787 he discovered two satellites revolving round the new planet, and subsequently found that it was accompanied by four others. It was soon noticed that Uranus had been observed by Flamsteed, Mayer, and Lemonnier, who had each supposed it to be one of the fixed stars. Their observations enabled Delambre to correct the elements of the orbit, and calculate tables of its motion. By means of his powerful telescopes Herschel determined the figure and rotation of Saturn, discovered the parallel belts on his surface, and perceived that the ring was double. In 1789 he discovered two new satellites belonging to this planet, and revolving within the ring. From some appearances indicated by the fixed stars, Herschel was led to conclude that the whole solar system is in motion about some distant centre, and that its direction is at present towards the constellation Hercules,—a conclusion which recent investigations have amply verified. His observations on nebulæ and double stars opened up a new field of research, boundless in extent and interesting by reason of the variety of the objects it presents to the attention of the observer. The extraordinary activity with which he pursued his favourite occupations is attested by 67 memoirs communicated from time to time to the Royal Society. A great part of these, however, are filled with speculations of no value to astronomy; and his taste was rather to observe astronomical phenomena than to engage in computations, or the more arduous and essential, though less fascinating, labours through which the science can be really benefited. In the course of the following chapters we shall have frequent occasion to allude to his discoveries, and his ingenious speculations concerning the constitution of the sun and the sidereal heavens.

Delambre, born 1749, died 1822.

Few individuals have contributed so eminently to the perfection of modern astronomy as Delambre, the late perpetual secretary of the Academy of Sciences. The scientific life of this illustrious astronomer did not commence till he had attained his 40th year; but from that time till his death it was occupied by a series of unremitting labours to enlarge the boundaries, and ameliorate the practice and theory of the science. Associated with Mechain, he was employed during the troubles of the revolution in measuring the meridian from Dunkirk to Barcelona,—a labour which was prosecuted with admirable zeal in the face of innumerable difficulties, and even dangers of the most formidable kind. By an immense number of excellent observations he determined the constants which enter into the formulæ deduced from theory by the profound researches of Lagrange and Laplace, and also formed a set of tables much more exact than any that had appeared before them. His *Astronomie Théorique et Pratique*, in three quarto volumes, contains the best rules and methods which have yet been devised for the guidance of the practical astronomer; and his *Histoire*, in six large volumes 4to, gives an account of every successive improvement which has been made in the science, and a full abstract of every work of celebrity which has been written respecting it, since the first rude observations of the Greeks to the end of the last century. It is invaluable to the historian, and will ever remain a proud monument of the profound learning and laborious research of its author.

Piazzi, born 1746, died 1826.

The observatory which was established at Palermo about the year 1790, under the active superintendence of Piazzi, holds a distinguished rank among the similar institutions of Europe. Piazzi, born in 1746, took the habit of the religious order of the *Theatins* at Milan, and finished his noviciate in the convent of St Anthony. Among his preceptors he had the advantage of counting Tiraboschi, Beccaria, Le Sœur, and Jacquier; and from these illustrious masters he speedily acquired a taste for mathematics and astronomy. After filling several professors' chairs in the colleges of the Jesuits at Rome and Ravenna, he was appointed in 1780 professor of the higher mathematics in the academy of Palermo. Here his first care was to reform the general system of education; and, by the alterations which he introduced, he contributed powerfully to dissipate the shades of ignorance, which, under the double influence of the Jesuits and the Inquisition, still lowered over the soil of Sicily. After having rendered this service to literature, he obtained from the prince of Caramanico, viceroy of the island, permission to found an observatory, and undertook a voyage to France and

History.

England, in order to provide the instruments necessary for the new establishment. Having procured a vertical circle, a transit, and some other instruments from Ramsden, he returned to Palermo and commenced his observations. His first care was to prepare a new catalogue of stars, the exact positions of which he justly considered as the basis of all true astronomy. In prosecuting this object he did not content himself with a single observation, but before he fixed the position of any star, observed it several times successively; and, by this laborious but accurate method, he constructed his first great catalogue of 6748 stars, which was crowned by the Academy of Sciences of France, and received with admiration by the astronomers of all countries. His constant practice of repeating his observations led to another brilliant result, the discovery of an eighth planet. On the 1st of January 1801, Piazzi, searching for the star 87 of the catalogue of Mayer, cursorily observed a small star of the eighth magnitude, between Aries and Taurus. On the following day he remarked that the star had changed its position, and accordingly supposed it to be a comet. He communicated his observations to Oriani, who, seeing that this luminous point had no nebulosity like the comets, and that it had been stationary and retrograded within comparatively small limits like the planets, computed its elements on the hypothesis of a circular orbit. He found that this hypothesis agreed with the observations, and other astronomers soon confirmed its accuracy. He gave the planet the name of *Ceres Ferdinandea*, in honour of Ferdinand, king of Naples, in whose dominions it was discovered, and who proposed to consecrate the event by a gold medal, struck with the effigy of the astronomer; but Piazzi, nobly preferring the interests of science to vain honours which could add nothing to his glory, requested that the money destined for this purpose should be employed in the purchase of an equatorial, which was still wanting to his observatory. In 1814 he published a new catalogue, extended to 7646 stars,—a splendid monument of indefatigable zeal and activity. He made an uninterrupted series of solstitial observations from 1791 to 1816, for the purpose of determining the obliquity of the ecliptic, which, compared with those of Bradley, Mayer, and Lacaille, in 1750, give a diminution of 44″ in a year. Besides these labours, sufficient to occupy a life of ordinary industry, Piazzi composed a number of memoirs for the different societies of which he was a member, and was intrusted by the Neapolitan government with several important commissions respecting the public instruction and the regulation of weights and measures in Sicily. He died in 1826, after having bequeathed his library and all his instruments to the observatory at Palermo, and assigned a liberal annuity to be devoted to the instruction of young men who evince a decided taste for astronomy.

Discovery of the planet Ceres.

Discovery of Pallas, Juno, and Vesta.

The discovery of Ceres led to that of three other little planets, circulating at nearly the same distance from the sun,—a circumstance unique in the construction of the solar system. On account of the smallness of the new planet, and the nebulosity by which it is surrounded, the difficulty of finding it after it had for some time ceased to be observed, was so considerable, that Dr Olbers of Bremen was induced to examine, with particular care, the configurations of all the small stars situated in the vicinity of its path, in order to have the means of detecting it at any time with greater facility. While engaged in making observations for this purpose, he discovered, on the 28th of March 1802, and nearly in the same place where he had before observed Ceres, another planet similar in size and appearance, to which he gave the name of *Pallas*. The extraordinary circumstance of the discovery of two planets having nearly the same mean distance, and performing their revolutions nearly in the same time, led Dr Olbers to imagine that Ceres and Pallas were fragments of a larger planet which had revolved in the same place, and been shattered by some external force or internal convulsion. The immediate consequence of this hypothesis was the probability of the existence of other fragments of the original planet, hitherto undiscovered; and that if such fragments existed, the planes of their orbits would pass through the points in which the orbits of Ceres and Pallas intersect each other. This bold idea acquired some probability from the subsequent discovery of two other planets in the very quarter of the heavens to which Dr Olbers had directed the attention of astronomers. *Juno* was discovered by M. Harding of Lilienthal, on the 2d of September 1804; and *Vesta*, by Dr Olbers himself, on the 29th of March 1807. Diligent observation did not for many years add to their number.

Improvements in optical instruments

Astronomy is a science which borrows the aid of several other sciences, with which its advancement is simultaneous. Instruments capable of appreciating or measuring the exceedingly minute quantities about which the observer now concerns himself, could only be produced in a very advanced state of mechanics. In the accurate graduation of large instruments, our English artists have long maintained an unrivalled superiority. Graham, a celebrated watch-maker, united to great dexterity in the mechanical arts a decided taste for observation; and the extraordinary improvements which he effected in the art of dividing form an era in the history of practical astronomy. The sector used by Bradley, in the observations which led to the discovery of the nutation, was of his construction, and he was also the inventor of the first compensation pendulum. Sisson, who succeeded him, maintained in this department the honour and pre-eminence of England. Bird was originally a weaver in Durham, and first gave proof of his mechanical genius by dividing dials for the watch-makers in a manner far superior to what had been commonly practised. He was employed by Sisson in the division of mathematical instruments, and recommended by that artist to Graham, who instructed him in his methods. He constructed the 8 feet quadrants employed in the Greenwich and Paris observatories, and another of 6 feet for Mayer at the observatory of Göttingen. Ramsden invented a machine for the more accurate division of instruments, on account of which he received a premium from the Board of Longitude. The mural quadrants of this artist were held in high estimation, and the transit instrument, sextant, and refracting micrometer, in passing through his hands, received considerable ameliorations. His astronomical instruments in general were considered the best that could be procured in Europe. Mr Troughton, who in his day stood the foremost of our British opticians, more than rivalled his predecessors. In the hands of this distinguished artist and astronomer, the division of instruments was carried to a degree of precision which at the time seemed incapable of being surpassed; while the great improvements he has introduced into the methods of constructing and mounting large instruments, and his ingenious inventions to elude natural obstacles, and guard against the accidental derangements from which it is impossible altogether to protect them, entitled him to the high place which he held by universal consent among the most eminent philosophers and original mechanicians of the age. The numerous circles and other instruments of his manufacture, whether in the hands of private individuals or deposited in the different public observatories, are considered still as the finest specimens of

Graham. Sisson. Bird. Ramsden. Troughton.

History.

what art has yet accomplished for the advancement of astronomical science. (See Supplement to Part I. for accounts of Modern Instruments.)

Progress of Physical Astronomy.

Having now endeavoured to give an account of the labours of those astronomers who have principally contributed to make us acquainted with the state of the heavens, and the order and succession of the various phenomena they exhibit, we will conclude this part of the article by briefly adverting to the profound researches of some illustrious mathematicians who have developed the theory of Newton, and raised the fabric of physical astronomy to its present proud elevation.

Problem of the three bodies.

Although the law of gravitation, as proposed by Newton, had from the first been admitted by all the most eminent astronomers of Britain, it was for a long time either opposed or neglected on the Continent. In fact, great improvements were required both in analysis and mechanics before it admitted of other applications than had been made by its great author, or could be regarded as any thing more than a plausible hypothesis. Newton demonstrated, that if two bodies only were projected in space, mutually attracting each other with forces proportional directly to their masses, and inversely to the squares of their distance, they would each accurately describe an ellipse round the common centre of gravity; and the spaces described by the straight line joining that centre and the moving body, would be proportional to the time of description, according to the second law of Kepler. But when it is attempted to apply Newton's law to the case of the solar system, great difficulties immediately present themselves. Any one planet in the system is not only attracted by the sun, but also, though in a greatly smaller degree, by all the other planets, in consequence of which it is compelled to deviate from the elliptic path which it would pursue in virtue of the sun's attraction alone. Now, the calculation of the effects of this disturbing force was the problem which geometers had to resolve. In its most general form it greatly transcends the power of analysis; but there are particular cases of it, and those too the cases presented by nature, in which, by reason of certain limitations in the conditions, it is possible to obtain an approximate solution to any required degree of exactness. For example, the Sun, Moon, and Earth form in a manner a system by themselves, which is very slightly affected by the aggregate attractions of the other planets. In the same way the Sun, Jupiter, and Saturn form another system, in which the motions are very little influenced by the action of any other body. In these two cases, then, the number of bodies to be taken into consideration is only three; and in this restricted form, the problem, celebrated in the history of analysis under the denomination of the *Problem of the Three Bodies*, is susceptible of being treated mathematically. With the hope of ameliorating the lunar tables, and of completing the investigations which Newton had commenced in the *Principia*, three distinguished geometers, Clairaut, D'Alembert, and Euler, about the middle of the last century, undertook, simultaneously, and without the knowledge of each other, the investigation of the problem of the three bodies, and commenced that series of brilliant discoveries which it is the glory of our own times to have seen completed.

Clairaut, born 1713, died 1765.

Clairaut's solution of the problem of the three bodies was presented to the Academy of Sciences in 1747, and was applied to the case of the moon. From this solution he deduced with great facility, not only the inequality of the variation, which Newton had obtained by a more complicated, though at the same time a very ingenious method, but also the evection, the annual equation, and many other inequalities which Newton had not succeeded in connecting with his theory. It happened, however, curiously enough, that in the calculation of one effect of the disturbing force, namely, the progression of the moon's apogee, Clairaut was led into an error which produced a result that threatened to overturn the system of gravitation. The error consisted in the omission of some of the terms of the series expressing the quantity in question, which he wrongly supposed to have only an insensible value; and by reason of this omission, his first approximation gave only half of the observed progressive motion of the apogee. As this result was confirmed by D'Alembert and Euler, who had both fallen into the same error, it seemed to follow, as a necessary consequence, either that the phenomenon depended on some other cause than the disturbing force of the sun, or that the law of gravity was not exactly proportional to the inverse square of the distance. The triumph which this result gave to the Cartesians was not of long duration. Clairaut soon perceived the cause of his error; and by repeating the process, and carrying the approximations farther, he found the computed to agree exactly with the observed progression,—a result which had the effect of dissipating for ever all doubt respecting the law of gravity. The researches of Clairaut were followed by a set of lunar tables, much more correct than any which had been previously computed.

The return of the comet of 1682, which Halley had predicted for the end of 1758, or beginning of 1759, afforded an excellent opportunity for putting to the test both the theory of gravity and the power of the new calculus. Clairaut applied his solution of the problem of the three bodies to the perturbations which this comet sustained from Jupiter and Saturn, and, after calculations of enormous labour, announced to the Academy of Sciences, in November 1758, that the comet would return in the beginning of the following year, and pass through its perihelion about the 15th of April. It returned according to the prediction, but passed its perihelion on the 13th of March. The correction of an error of computation reduced the difference to nineteen days; and if Clairaut had been aware of the existence of the planet Uranus, he might have come still nearer the truth.

Besides these important researches on the system of the world, Clairaut composed an admirable little treatise on the figure of the earth, in which he gave the differential equations, till then unknown, of the equilibrium of fluids, whether homogeneous or heterogeneous, supposing an attractive force, following any law whatever, to exist among the molecules. He applied these equations to the earth; demonstrated that the elliptic figure satisfies the conditions of equilibrium; assigned the ellipticity of the different strata of which the earth may be supposed to be formed, together with the law of gravitation at the exterior surface. He likewise discovered the important theorem which establishes a relation between the oblateness of the terrestrial spheroid and the increase of gravitation towards the poles, on every supposition which can be imagined relative to the interior construction of the earth. By means of this theorem the ellipticity of the spheroid is deduced from observations of the lengths of the seconds pendulum at different points of the earth's surface.

D'Alembert, born 1717, died 1783.

D'Alembert, as has already been mentioned, presented a solution of the problem of the three bodies to the Academy of Sciences at the same time with Clairaut. In the year 1749 he published his treatise on the precession of the equinoxes,—a work remarkable in the history of analysis and mechanics. By means of his newly invented

History.

calculus of *Partial Differences*, and the discovery of a fertile principle in dynamics, he determined from theory the rate of the precession, which is nearly 50″ in a year. He also determined the nutation of the earth's axis, which had been discovered by Bradley, and assigned the ratio of the axes of the small ellipse which the true pole of the earth describes around its mean place, in the same time in which the nodes of the lunar orbit complete a revolution. The solution of this problem led to the determination of the ratio of the attractive forces of the sun and moon, which D'Alembert found to be that of seven to three very nearly; whence he inferred that the mass of the earth is 70 times greater than that of the moon. He proved likewise that the precession and nutation are the same in every hypothesis concerning the interior constitution of the earth. In 1754 he published the first two volumes of his *Researches on the System of the World*. In this work he applied the formulæ by which he had calculated the motions of the moon to the motions of the planets disturbed by their mutual attraction, and pointed out the simplest method of determining the perturbations of the motions of a planet occasioned by the action of its own satellites. D'Alembert also treated the subject of the figure of the earth in a much more general manner than had been done by Clairaut, who had confined his investigations to the case of a spheroid of revolution. He determined the attraction of a spheroid of small eccentricity, whose surface can be represented by an algebraic equation of any order whatever, and even supposing the spheroid to be composed of strata of different densities.

The works of D'Alembert, which are extremely numerous, abound generally in profound and original views, and contributed greatly to the advancement of the physical and mathematical sciences; but it is to be regretted that they are very frequently deficient in that perspicuity and order so necessary in abstruse speculations, and that the course of his reasoning can be followed with difficulty when he descends into the detail of analytical operations. He had a horror of calculation, and delighted in general considerations and speculations which frequently turned on matters of pure curiosity.

Euler, born 1707, died 1783.

The first memoir of Euler on the planetary perturbations was transmitted to the secretary of the Academy of Sciences in July 1747, some months before Clairaut and D'Alembert had communicated their solutions of the problem of the three bodies, and it carried off the prize which the academy had proposed for the analytical theory of the motions of Jupiter and Saturn. In this memoir Euler gave the differential equations of the elements of the disturbed planet, but suppressed the analysis by which he had been conducted to them. This analysis, however, he subsequently expanded in two memoirs, the first of which appeared in the Berlin Memoirs in 1749, and the second in those of Petersburg in 1750. Of these supplementary memoirs the first is remarkable on several accounts. It contains the first example of a method which has been fruitful of important consequences—namely, that of the variation of the arbitrary constants in differential equations, and the development of the radical quantity which expresses the distance between two planets in a series of angles, multiples of the elongations. The expressions which he gave for the several terms of this series were simple and elegant; and he demonstrated a curious relation subsisting among any three consecutive terms, by means of which all the terms of the series may be calculated from the first two. He was thus enabled to develop the perturbing forces in terms of the sines and cosines of angles increasing with the time, and thereby to surmount a very great analytical difficulty. Notwithstanding, however, the great merit of Euler's memoir, several of the formulæ expressing the secular and periodic inequalities were found to be inaccurate; and in order to procure a correction of these errors, and give greater perfection to so important a theory, the academy again proposed the same subject for the prize of 1752. This prize was also carried off by Euler. In the memoir which he presented on this occasion, he considered simultaneously the motions of Jupiter and Saturn, and determined, in the first instance, the amount of their various inequalities, independently of the consideration of the eccentricities of their orbits. Pushing the approximations farther, and having regard to the inequalities depending on the eccentricities, he arrived at a most important result relative to the periodic nature of the inequalities occasioned by the mutual perturbations of the planets; which laid the foundation of the subsequent discovery by Lagrange and Laplace of the permanent stability of the planetary system. He demonstrated that the eccentricities and places of the aphelia of Jupiter and Saturn are subject to constant variation, confined, however, within certain fixed limits, which it never exceeds; and he computed that the elements of the orbits of the two planets recover their original values after a lapse of about 30,000 years. In the year 1756 the Academy of Sciences crowned a third memoir of Euler on the same subject as the two former, namely, the inequalities of the motions of the planets produced by their reciprocal attractions. This memoir, analytically considered, is also of great value. The method which he followed and illustrated has since been generally adopted in researches of the same nature, and consists in regarding as variable, in consequence of the disturbing forces, the six elements of the elliptic motion, viz. 1*st*, the greater axis of the orbit, which, by the law of Kepler, gives the ratio of the differential of the mean longitude to the element of the time; 2*d*, the epoch of this longitude; 3*d*, the eccentricity of the orbit; 4*th*, the motion of the aphelion; 5*th*, the inclination of the orbit to a given fixed plane; and, 6*th*, the longitude of the node. By considering separately the variations introduced into each of these elements by the disturbing forces, Euler obtained some important results; but even in this memoir his theory was not rendered complete. He did not consider the variation of the epoch; and the expression which he gave for the motion of the aphelion did not include that part of it which depends on the ratio of the eccentricities of the orbits of the disturbed and disturbing planet. Besides, the present memoir, like the two former, contained several errors of computation, which, by leading to results known to be wrong, probably prevented the author himself from being aware of the full value of the ingenious methods of procedure which he had exposed. Euler concluded this important memoir by making an extended application of his formulæ to the orbit of the earth as disturbed by the action of the planets. From some probable suppositions, first employed by Newton, relative to the ratios of the masses of the planets to that of the sun, he determined the variation of the obliquity of the ecliptic at 48″ in a century,—a result which agrees well with observation. By this determination the secular variation of the obliquity of the ecliptic, which had been regarded by Lahire, Lemonnier, D'Alembert, and other eminent astronomers, as uncertain, was placed beyond doubt. The three memoirs which we have mentioned contain the principal part of Euler's labours on the perturbations; but physical astronomy is indebted to him for many other researches. He gave a solution of the problem of the precession of the equinoxes, and made several important steps in the lunar theory, with which he seems to have

History.

occupied himself before he undertook the investigation of the planetary perturbations. In the year 1772, when entirely blind, he directed his son, Albert Euler, and two illustrious pupils, Krafft and Lexell, in the composition of a work of enormous labour on the same subject, which was undertaken with a view to discover the cause of the moon's acceleration. This work was concluded with a set of lunar tables deduced entirely from theory; but they were found to be far inferior to those of Mayer, and in some respects hardly equal to those of Clairaut.

The labours of Euler form an epoch in the history of the mathematical sciences. From the arithmetic of sines, and the simplest formulæ of trigonometry up to the variation of the arbitrary constants of differential equations, there is hardly an analytical theory which has not received extension or improvement from the creative powers of his great mind. The transactions of the Berlin and Petersburg Academies are filled with his inestimable productions; and if fecundity were not itself one of the attributes of genius, the number of the profound and laborious researches in which he was engaged would appear altogether incredible.

Mayer's lunar tables.

The first theory of Euler formed the basis of the excellent lunar tables which were calculated by Tobias Mayer, and first published in the Memoirs of the Academy of Göttingen in 1753. Mayer was a skilful astronomer, and determined the co-efficients of the arguments of the different lunar inequalities from his own observations. He continued to correct and improve his tables till the time of his death, which happened in 1762, when a copy of them, containing his last corrections, was presented by his widow to the Board of Longitude in London. Bradley ascertained their accuracy by comparing them with a great number of his own observations, and made so favourable a report concerning them, that the Board of Longitude presented the widow of Mayer with a gratuity of L.3000. They were printed along with the author's lunar theory in 1765. Subsequently, the Board of Longitude directed Mason, who had been assistant to Bradley, to revise them, under the superintendence of Dr Maskelyne. Mason compared them with about 1200 of Bradley's observations; he corrected the co-efficients of Mayer, and introduced some new equations which had been indicated by that astronomer, but which he had considered as too uncertain, or of too small a value, to render it necessary to load his tables with them. Mayer's tables, thus corrected, were published in 1784, and for a long time continued to be the most accurate that had appeared.

The solution of the problem of the three bodies by Clairaut, D'Alembert, and Euler, gave rise to many other important works relative to the theory of the moon, into the merits of which, however, our limits will not permit us to enter. Thomas Simpson, Walmesley, Frisi, Lambert, Schulze, and Matthew Stewart, treated the subject with more or less success; but the complete explication of the theory of the lunar and planetary perturbations was reserved for two mathematicians, whose discoveries perfected the theory of gravitation, and explained the last inequalities which remained to be accounted for in the celestial motions,—we mean Lagrange and Laplace.

Lagrange, born 1736, died 1813.

In the year 1764, the Academy of Sciences of Paris, which had so successfully promoted the great efforts that had already been made to perfect the theory of attraction, proposed for the subject of a prize the theory of the libration of the moon. This was considered as an appeal to the genius of Lagrange, whose splendid talents had suddenly shone forth in two profound papers on the theory of sound, inserted among the Memoirs of the Turin Academy, and in which the calculus of variations was first explained and made use of. Lagrange had the honour of carrying off the prize; but although he treated the subject in a manner altogether new, and with extraordinary analytical skill, he did not on this occasion arrive at a complete solution of the problem. In 1766 he obtained another prize for a theory of Jupiter's satellites. In the admirable memoir which Lagrange presented to the academy on this subject, he included in the differential equations of the disturbed motion of a satellite, the attracting force of the sun, as well as of all the other satellites, and thus, in fact, had to consider a problem of six bodies. His analysis of this problem is remarkable, inasmuch as it contained the first general method which was given for determining the variations which the mutual attractions of the satellites produce in the forms and positions of their orbits, and pointed out the route which has since been so successfully followed in the treatment of similar questions.

Discovery of the invariability of the mean distances.

Of all the grand discoveries by which the name of Lagrange has been immortalized, the most remarkable is that of the invariability of the mean distances of the planets from the sun. We have already mentioned that Euler had perceived that the inequalities of Jupiter and Saturn, in consequence of their mutual actions, are ultimately compensated, though after a very long period. In prosecuting this subject, which Euler had left imperfect, Laplace had discovered that, on neglecting the fourth powers in the expressions of the eccentricities and inclinations of the orbits, and the squares of the disturbing masses, the mean motions of the planets, and their mean distances from the sun, are invariable. In a short memoir of 14 pages, which appeared among those of the Berlin Academy for 1776, Lagrange demonstrated generally, and by a very simple and luminous analysis, that whatever powers of the eccentricities and inclinations are included in the calculation of the perturbations, no secular inequality, or term proportional to the time, can possibly enter into the expression of the greater axis of the orbit, or, consequently, into the mean motion connected with it by the third law of Kepler. From this conclusion, which is a necessary consequence of the peculiar conditions of the planetary system, it results that all the changes to which the orbits of the planets are subject in consequence of their reciprocal gravitation, are periodic, and that the system contains within itself no principle of destruction, but is calculated to endure for ever.

In 1780 Lagrange undertook a second time the subject of the moon's libration; and it is to the memoir which he now presented to the Berlin Academy that we must look for the complete and rigorous solution of this difficult problem, which had not been resolved before in a satisfactory manner, either on the footing of analysis or observation. In the same year he obtained the prize of the Academy of Sciences on the subject of the perturbations of comets. In 1781 he published, in the Berlin Memoirs, the first of a series of five papers on the secular and periodic inequalities of the planets, which together formed by far the most important work that had yet appeared on Physical Astronomy since the publication of the *Principia*. This series did not, properly speaking, contain any new discovery; but it embodied and brought into one view all the results and peculiar analytical methods which had appeared in his former memoirs, and contained the germs of all the happy ideas which he afterwards developed in the *Mécanique Analytique*.

On account of the brilliant discoveries and important labours which we have thus briefly noticed, Lagrange must be considered as one of the most successful of those illustrious individuals who have undertaken to perfect the theory of Newton, and pursue the principle of gravi-

History.

tation to its remotest consequences. But the value of his services to science are not limited to his discoveries in physical astronomy, great and numerous as they were. After Euler, he has contributed more than any other individual to increase the power and extend the applications of the calculus, and thereby to arm future inquirers with an instrument of greater power, by means of which they may push their conquests into new and unexplored fields of discovery.

Laplace, born 1749, died 1827.

With the name of Lagrange is associated that of Laplace, whose rival labours divided the admiration of the scientific world during half a century. Like Newton and Lagrange, Laplace raised himself at an early age to the very highest rank in science. Before completing his 24th year, he had signalized himself by the capital discovery of the invariability of the mean distances of the planets from the sun, on an hypothesis restricted, indeed, but which, as we have already mentioned, was afterwards generalized by Lagrange. About the same time he was admitted into the Academy of Sciences, and thenceforward devoted himself to the development of the laws which regulate the system of the world, and to the composition of a series of memoirs on the most important subjects connected with astronomy and analysis. His researches embraced the whole theory of gravitation; and he had the high honour of perfecting what had been left incomplete by his predecessors.

Discovers the cause of the moon's acceleration.

Among the numerous inequalities which affect the motion of the moon, one still remained which no philosopher as yet had been able to explain. This was the acceleration of the mean lunar motion, which had been first suspected by Dr Halley, from a comparison of the ancient Babylonian observations, recorded by Hipparchus, with those of Albategnius and the moderns. The existence of the acceleration had been confirmed by Dunthorne and Mayer, and its quantity assigned at 10″ in a century, but the cause of it remained doubtful. Lagrange demonstrated that it could not be occasioned by any peculiarity in the form of the earth; Bossut ascribed it to the resistance of the medium in which he supposed the moon to move; and Laplace himself at first explained it on the supposition that gravity is not transmitted from one body to another instantaneously, but successively in the manner of sound or light. Having afterwards remarked, however, in the course of his researches on Jupiter's satellites, that the secular variation of the eccentricity of the orbit of Jupiter occasions a secular variation of the mean motions of the satellites, he hastened to transfer this result to the moon, and had the satisfaction to find that the acceleration observed by astronomers is occasioned by the secular variation of the eccentricity of the terrestrial orbit. This was the last celestial phenomenon which remained to be accounted for on the principle of gravitation.

Inequalities of Jupiter and Saturn.

Another discovery relative to the constitution of the planetary system, which does infinite honour to the sagacity of Laplace, is the cause of the secular inequalities indicated by ancient and modern observations in the mean motions of Jupiter and Saturn. On examining the differential equations of the motions of these planets, Laplace remarked, that as their mean motions are nearly commensurable (five times the mean motion of Saturn being nearly equal to twice that of Jupiter), those terms of which the arguments are five times the mean longitude of Saturn, minus twice that of Jupiter, may become very sensible by integration, although multiplied by the cubes and products of three dimensions of the eccentricities and inclinations of the orbits. The result of a laborious calculation confirmed his conjecture, and showed him that in the mean motion of Saturn there existed a great inequality, amounting at its maximum to 48′ 2″·3, and of which the period is 929 years; and that in the case of Jupiter there exists a corresponding inequality of nearly the same period, of which the maximum value is 19′ 46″, but which is affected by a contrary sign, that is to say, diminishes while the first increases, and *vice versa*. He also perceived that the magnitude of the co-efficients of these inequalities, and the duration of their periods, are not always the same, but participate in the secular variations of the elements of the orbits.

Figure of the earth.

The theory of the figures of the planets, scarcely less interesting than that of their motions, was also greatly advanced by the researches of Laplace. He confirmed the results of Clairaut, Maclaurin, and D'Alembert, relative to the figure of the earth, and treated the question in a much more general way than had been done by those three great mathematicians. From two lunar inequalities depending on the non-sphericity of the earth, he determined the ellipticity of the meridian to be $\frac{1}{306}$ very nearly.

Tides.

Newton, in the *Principia*, explained the cause of the phenomena of the tides, and laid the foundations of a theory which was prosecuted and extended by Daniel Bernoulli, Maclaurin, Euler, and D'Alembert; but as no one of these geometers had taken into account the effects of the rotatory motion of the earth, the subject was in a great measure new when it was taken up by Laplace in 1774. Aided by D'Alembert's recent discovery of the calculus of *Partial Differences*, and by an improved theory of hydrodynamics, he succeeded in obtaining the differential equations of the motion of the fluids which surround the earth, having regard to all the forces by which these motions are produced or modified, and published them in the Memoirs of the Academy in 1775. By a careful examination of these equations, he was led to the curious remark, that the differences between the heights of two consecutive tides about the time of the solstices, as indicated by Newton's theory, are not owing, as Newton and his successors had supposed, to the inertia of the waters of the ocean, but depend on a totally different cause, namely, the law of the depth of the sea, and that it would disappear entirely if the sea were of a uniform and constant depth. He also arrived at the important conclusion, that the fluidity of the sea has no influence on the motions of the terrestrial axis, which are exactly the same as they would be if the sea formed a solid mass with the earth. The same analysis conducted him to the knowledge of the conditions necessary to insure the permanent equilibrium of the waters of the ocean. He found that if the mean density of the earth exceeds that of the sea, the fluid, deranged by any causes whatever from its state of equilibrium, will never depart from that state but by very small quantities. It follows from this, that, since the mean density of the earth is known to be about five times greater than that of the sea, the great changes which have taken place in the relative situation of the waters and dry land must be referred to other causes than the instability of the equilibrium of the ocean.

Precession of the equinoxes.

Closely connected with the problem of the tides is that of the precession of the equinoxes, which also received similar improvements in passing through the hands of Laplace. He demonstrated, as has just been mentioned, that the fluidity of the sea has no influence on the phenomena of precession and nutation. He considered some of the effects of the oblate figure of the earth which had not been attended to by D'Alembert, and showed that the annual variation of the precession causes a corresponding variation in the length of the tropical year, which at present is about 9 or 10 seconds shorter than it was in the time of Hipparchus. He proved that the secular inequa-

History.

lities of the motions of the earth and moon have no sensible effect in displacing the axis of the earth's rotation; and he determined the nutation of the lunar orbit corresponding to the nutation of the terrestrial equator.

Jupiter's satellites.

Physical astronomy is also indebted to Laplace for a complete theory of the system of Jupiter's satellites, from which Delambre constructed a set of tables which represent the motions of these bodies with all desirable accuracy. And when to these numerous and most important researches we add the mathematical theories of molecular attraction, and the propagation of sound, together with many great improvements in analysis,—and reflect, besides, that he is the author of the *Mecanique Céleste*, the *Système du Monde*, and the *Théorie des Probabilités*,—we shall not hesitate to rank him next to Newton among the greatest benefactors of the mathematical and physical sciences.

By the brilliant discoveries of Laplace, the analytical solution of the great problem of physical astronomy was completed. The principle of gravity, which had been discovered by Newton to confine the moon and the planets to their respective orbits, was shown to occasion every apparent irregularity, however minute, in the motions of the planets and satellites; and those very irregularities which were at first brought forward as objections to the hypothesis have been ultimately found to afford the most triumphant proofs of its accuracy, and have placed the truth of the Newtonian law beyond the reach of all future cavil. Such is the state to which analysis has now attained, that the geometer embraces in his formulæ every circumstance which affects the motions or positions of the different bodies of the planetary system; and the conditions of that system being made known to him at any given instant of time, he can determine its conditions at any other instant in the past or future duration of the world. He ascends to remote ages to compare the results of his theories with the most ancient observations; he passes on to ages yet to come, and predicts changes which the lapse of centuries will hardly be sufficient to render sensible to the observer. But notwithstanding the proud elevation to which the theory of astronomy has been raised, it is still far from having reached the limit beyond which further refinement becomes superfluous. The masses of the planets, and some other elements, remain to be determined with still greater precision, by a diligent comparison of the analytical formulæ with good observations; and the labours of the geometer may still be beneficially employed in giving greater simplicity to the calculus, or in extending its power over subjects which have hitherto eluded its grasp. The recent discovery of several periodic comets completing their revolutions in comparatively short intervals of time, opens up an interesting field for speculation and research, and will doubtless be the means of throwing light over some curious and as yet very obscure, points, respecting the appearances, motions, and physical constitution of those strange bodies.

History.

In the other departments of the science, also, numerous questions still remain to be discussed, the solution of which will occupy and reward the future labours of the astronomer, and in which much progress has been made during the present century, by means of the powerful instruments now employed at the great observatories of every civilized country, and the improved methods of analysis brought to bear upon the results of observation. The curious phenomena of double and multiple stars, some of which appear to form connected systems of bodies revolving about one another, or a common centre of motion,—the variable stars,—the proper motions of the stars,—the translation of the solar system in space,—the progressive condensation of nebulæ,—are subjects still in a great measure new; for it is only of late years that observers have begun to direct the requisite attention towards them, or indeed have been in possession of instruments of sufficient power and delicacy to observe and measure the minute changes which take place beyond the boundaries of our own system. (T. G.)

Supplement to Part I.—1853.

The discoveries in astronomy during the present century have been so brilliant and numerous, and the progress in every department is so rapid, and involves so many details, that we should despair of adequately representing even the outlines of the leading features in such a way as to benefit the reader within the compass of the few pages which can be allotted to the extension of the history which has already been given. We propose, instead of attempting this, to give as briefly as possible an account of the journals, institutions, and observatories which have been chiefly instrumental in producing this rapid progress of the science, and especially to draw the attention of the English student to the works of those great German astronomers, with which he must make himself conversant if he would ever desire to understand the nature of the advances which have been made, and which are absolutely indispensable if he hope to add anything to the fabric which has been erected. The supplement thus given will familiarize the reader with the sources of the various discoveries and investigations which he will meet with in the subsequent parts of the article; and there is scarcely a subject of importance in any department of astronomy which will not receive some elucidation.

Account of Serial Works or Journals, Institutions, and Observatories which have chiefly contributed to the improvement of Astronomy in the nineteenth century.

The history of astronomy has been given with sufficient detail to the beginning of the present century; and, in conformity with the plan already indicated, we propose to exhibit the sources of its rapid advancement since that time, by giving short notices of the principal publications and institutions which have mainly contributed to its progress.

Of the serial works in question, the first to be mentioned is Zach's *Monatliche Correspondenz*, which, commencing with the year 1800, was, till 1813, the leading astronomical journal in Europe. The basis of this work was one conducted previously by Zach, entitled *Allgemeine Geographische Ephemeriden.* This work was devoted chiefly to geographical researches; but Zach was induced to alter his plan, and to commence, on a more extended scale, the celebrated *Correspondenz*, or, as it was entitled by its able editor, *Monatliche Correspondenz zur Beförderung der Erd und Himmel's Kunde.* Soon after its commencement (that is at the beginning of 1801), Piazzi discovered the planet Ceres, the complete history of which discovery, as well as of the discoveries of Juno, Pallas, and Vesta, must be looked for in its pages.

At the end of 1813 this journal was discontinued, having been really conducted from the year 1807 by Lindenau, though Zach was still the responsible editor. Its abrupt termination was due to the French war, in which Lindenau felt himself called upon to take part on the staff of the Duke of Weimar. This war produced a suspension of many of the literary and scientific works of Germany; and it was not till the beginning of 1816 that a new journal was commenced, under Lindenau's direction, bearing the title of *Zeitschrift für Astronomie und verwandte Wissenschaften.* This work, in which Lindenau was assisted by Bohnenberger, differed from its predecessor chiefly in being of a more strictly astronomical character, each number consisting of articles comprehended under one or another of the three divisions, Original Treatises on Astronomical Subjects, Critical Notices of Astronomical Works, and Correspondence.

One of the most valuable portions of this work, which was

History.

not carried on beyond the year 1818, is the elaborate introduction by Lindenau. It contains a long historical summary of the progress of astronomy during the period of suspension of Zach's *Correspondenz* from 1813 to 1816, thus supplying a gap in the continuous history of the astronomy of the present century.

Amongst the most remarkable of the contributions to the *Zeitschrift*, we may mention the following:—

In vol. i., a paper by Gauss on the *Theory of Certainty in Observations;* also two or three papers by Bohnenberger on the *Precessional Motion of Stars for long Intervals of Time;* and a complete list of the works of Lagrange.

In vol. ii., amongst other interesting papers and letters, an essay by Littrow, *On the Correction to the Mean Refraction due to the Thermometer; A Catalogue of the Arabic Names of the Stars*, by Zach; *Observations* by Bessel, *especially of Right Ascension, for the Determination of the Parallax of* 61 *Cygni; A History of the Greenwich Observatory* by Lindenau; and an *Investigation of the Orbit of the Comet of Pons.*

In vol. iii., a paper by Zach, *On Tobias Mayer's Observations of Uranus;* and one by Littrow, *On the Correction of the Solar Tables.*

In vol. iv., Westphal *On the Periods of Variable Stars;* Plana *On the Changes in the Places of the Fixed Stars, produced by the Secular Motion of the Plane of the Ecliptic;* A letter from Struve *On the Commencement of his Operations at the Observatory at Dorpat.*

In vol. vi., the most important article is by Encke, *On the most probable Orbit of the Comet of* 1680. Other works worthy of notice are,—*On the Accurate Computation of Nutation and Aberration*, by Bessel. *On the General Formulæ for Computation of the Corrections of Six Elements, according to the Method of Least Squares*, by Plana.

The *Zeitschrift* was brought suddenly to a conclusion with the sixth volume, at the end of the year 1818.

The epoch of this journal was one of very great importance to astronomy. Old instruments and old methods were being superseded by new ones. Telescopes of greater power were mounted equatorially in several observatories; and meridian instruments of improved construction were erected. At Greenwich, Troughton's mural circle and transit instrument had been erected, and a series of excellent observations had been begun under Pond's direction. On the continent, Reichenbach's meridian circles were being introduced into every observatory; and the first series of the Königsberg observations, made by Bessel with an instrument of this class, had been published.

But above all, the incomparable *Fundamenta Astronomiæ* of Bessel was published at this time, giving the accurate results of Bradley's star observations, and new values of every element necessary for their reduction, by investigations based on the observations themselves.

The *Tabulæ Regiomontanæ*, or synopsis of all the fundamental quantities needed by the astronomer, which is still indeed an indispensable text book, was published by Bessel in 1830.

Another serial work which must be mentioned, is Zach's *Correspondance Astronomique, Geographique, Hydrographique, et Statisque*, of which the first letter is dated June 1818. This was published in the French language, and was issued from Genoa where Zach was residing. The series terminated with the thirteenth volume in 1825.

In connection with Zach's journals, it may be mentioned, that a complete index to the *Monatliche Correspondenz* was compiled recently by Dr Galle, and published in 1848, preceded by a short memoir of the Baron de Zach.

The journal which succeeded the *Zeitschrift*, was the celebrated *Astronomische Nachrichten*, which is continued at the present time with unremitted utility. It was commenced in 1821 at Altona, under the editorship of Professor Schumacher. The abilities and untiring zeal of its editor, who continued his services till the time of his death in 1850, were mainly instrumental in raising the *Nachrichten* to the high rank which it possesses.

For a biographical account of Schumacher, the reader may consult the eleventh volume of the *Notices of the Royal Astronomical Society.* It will suffice here to mention his principal works. They are, 1. A Collection of Astronomical Tables; 2. Ephemerides of the bright planets from 1820 to 1829, and of the distances of the bright planets from the moon, from 1822 to 1831, inclusive; 3. His Astronomical *Jahrbuch*, from 1836 to 1844, which, in addition to a variety of useful tables, contains numerous popular scientific views and summaries by the greatest geometers of the continent.

History.

In 1829, the Royal Astronomical Society of London awarded to Schumacher their gold medal for the *Nachrichten;* and, in illustration of the acknowledged character of the work, we quote the following extract from the eulogium pronounced by Sir J. Herschel on that occasion:—" Amongst those numerous and talented individuals throughout the continent and in England, who are attached to astronomy professionally, or from love to the science, the *Astronomische Nachrichten* of Professor Schumacher establishes a point of concourse—a complete bond of reunion. We have there a theatre of discussion of whatever is most new and refined in the theory and practice of astronomy; the utmost delicacies of computation and scrupulous investigation of instrumental errors are given by those most competent to reply and judge of them. To its pages, observations of every kind find their way, especially those which depend for their utility on corresponding observations, or which lose their interest or importance by long suppression. Not a comet appears, but *there* we find its elements handed in from all quarters with wondrous rapidity. Occultations, moon-culminating observations, computations of longitudes and latitudes, disquisitions on practical points, descriptions, advertisements, and prices of instruments,—in a word, everything which can awaken and keep alive attention to the science,—everything that can facilitate the contact of mind with mind. . . . . . The *Astronomische Nachrichten*, in fact, contains the history of astronomical science for the last thirty years; it is the necessary complement and commentary of almost every astronomical publication of value, and is the complete repertory of modern theory and practice, not of Europe, but of the civilized world."

This excellent serial still flourishes under the able editorship of Dr Petersen, and continues to be the great medium of communication for astronomers.

A serial work of the same character as the *Nachrichten*, and performing similar services for the science of astronomy in America, has lately appeared under the editorship of Mr B. A. Gould of Cambridge University, Massachusetts. The first volume was completed in April 1851, and the work has gone on uninterruptedly to the present time.

In proceeding to give some account of the principal ephemerides, we shall confine ourselves chiefly to the French *Connaissance des Temps;* the English *Nautical Almanac;* the Berlin *Jahrbuch;* the *Effemeridi di Milano;* and the *American Ephemeris and Nautical Almanac*, of which the first volume for 1855 has recently been published.

The series of the *Connaissance des Temps* commenced in the seventeenth century, under the superintendence of Picard. Lalande in the following century introduced great changes and improvements, and the work remains substantially as he left it. In both the ancient and the modern volumes, the places of the planets are given only approximately at intervals of several days, though in the modern volumes the daily places of the sun and moon, and other solar and lunar elements, are given with more detail and precision, and provision is made for the determination of the longitude at sea by a copious table of lunar distances for every three hours for the bright stars and the planets. The places are given of a copious catalogue of fixed stars, and particular attention has been paid to render the work useful for maritime purposes. It has always been the vehicle for the publication of some of the most valuable papers of the French astronomers; and in particular we may mention, that it contains the whole of Leverrier's admirable discussions leading to the discovery of the planet Neptune. For many years it was published under the direction of the Academy of Sciences; but was afterwards placed under the direction of the *Bureau des Longitudes.* The modern volumes contain an excellent list of geographical latitudes and longitudes, well determined.

The English *Nautical Almanac* dates from 1767, for which year the first volume was issued in 1766. It was undertaken in connection with the parliamentary commission for the " Discovery of the Longitude at Sea." Dr Maskelyne, the Astronomer-Royal, conducted it for many years. It was afterwards succes-

sively under the direction of the celebrated Dr Thomas Young, secretary to the Board of Longitude, and the Astronomer-Royal, Mr Pond.

About the year 1830, however, the construction of the *Almanac* was found to be defective, and reference was made by the Lords Commissioners of the Admiralty to the Royal Astronomical Society, requesting that body to consider what improvements it would be desirable or necessary to make in the work. A committee was consequently appointed by the society, including every eminent astronomer in the British Isles, together with Professor Struve of Dorpat, to report upon the subject; and in consequence of their recommendations, the work was brought to its present excellent form. One of the greatest changes in principle made in the *Almanac* was its adaptation to the wants of the theoretical and practical, as well as of the nautical astronomer, to which last it was formerly almost exclusively devoted. This scheme introduced a great deal of additional computation of the accurate places of the sun, moon, and planets for every day of the year; the introduction of mean time instead of apparent; the supplying of the constants for the corrections of the mean places of the stars; and finally, a more extensive list of fundamental or well-observed stars, with their mean places deduced with scrupulous accuracy for every year, and with the elements of their reduction. In addition, the times of all the phenomena of Jupiter's satellites are given; a list of moon-culminating stars, and of all stars down to the sixth magnitude which could be occulted by the moon, together with the elements for facilitating the computations of the occultations; and lastly, a list of remarkable phenomena likely to be useful. Every possible information with regard to the places of the large planets, and of the four small planets first discovered, is given, and complete elements for every solar and every lunar eclipse during the year; supplying, in fact, every reasonable want of the general as well as of the nautical astronomer. One important addition to this work is the construction of ephemerides of the planets calculated for the meridian of Greenwich. By this means the observed and the tabular places of these bodies can be immediately compared, and a very easy reduction renders these places almost equally applicable for other observatories not differing greatly in longitude, including all in the British Isles, and several of the continental observatories. The *Nautical Almanac* is so conducted that the volume is always published about three years in advance of the current year, and its price has recently been reduced from five shillings to half that sum.

The first volume of the Berlin *Jahrbuch* was published in 1774 for the year 1776. Its object was twofold, viz., to supply the want of such a work in which Germany had been for some time singular, and "to obtain a repertory for all observations, information, remarks, and treatises connected with astronomical science." From its commencement the *Jahrbuch* was published under the inspection and sanction of the Royal Academy of Sciences at Berlin. The volumes from 1776 to 1783 inclusive, bear on their title-page the name of no responsible superintendent; but the volume for 1784, and those that followed it for a long period, were under the immediate editorship of Bode, and after he relinquished the office, it was put into the hands of Encke, its present superintendent. It has always been famed for the valuable collections of observations and astronomical papers contained in its second part, which forms one of the great storehouses of astronomical data from its establishment to the present time. Its contents are particularly valuable in this respect for the period before the establishment of the *Monatliche Correspondenz*, and it is here that the astronomer must look for the records of his science in the last century.

Almost all the articles in the second part of the first volume are by Lambert, and though this and several succeeding volumes are anonymous, yet it would appear that they were under his management. At the present time it is one of the most useful publications of its class, and is the only one which provides original ephemerides for the recently discovered small planets. Those given in the supplements to the *Nautical Almanac* are taken from the *Jahrbuch*, only adapted to the meridian of Greenwich.

The Milan Ephemeris (*Effemeridi di Milano*) is a useful publication commencing with the year 1800. The modern volumes are sometimes found useful from their supplying some elements of the planetary motions which are wanting in other ephemerides. It contains many valuable observations and papers of the Italian astronomers. Other ephemerides are those of Bologna, Coimbra, and Cadiz; but these require no particular mention.

Very recently an American *Ephemeris and Nautical Almanac* has appeared, which promises to be of great service. It is printed in a large octavo volume, and is published under the authority of the Secretary of the Navy. It is at present under the superintendence of Lieutenant C. H. Davis, U.S.N., the theoretical part being placed under the special direction of Professor Peirce of Harvard College, Cambridge.

This work does not copy implicitly any existing nautical almanac, but, retaining what is best in our own and others, modifies the arrangement in a way which promises to be more generally convenient. One great peculiarity in this work is the separation between the part designed exclusively for the purpose of navigation, and that which is generally useful for the theoretical or practical astronomer. In the second part the places of the stars and the planets are referred to the meridian of Washington, and in the computations, the best elements at present known are scrupulously employed. Thus, for the star corrections, Peters's constants of precession, nutation, &c., have been adapted to Bessel's formulæ; and with regard to the lunar computations, the elements are based on Plana's theory, but include Hansen's inequalities and secular changes of the mean motion and the perigee; and Airy's corrections of the elements derived from the reduction of the ancient Greenwich observations. For the planetary computations, the latest corrections of the elements of each planet have been employed. For Mercury, Leverrier's theory has been used (*Conn. des Temps* for 1848); for Venus and Mars, Mr H. Breen's corrections have been applied to Lindenau's elements (*Memoirs of Royal Astronomical Society*, vols. xviii. and xx.); for Jupiter and Saturn, Bouvard's tables have been used with some changes, and Bessel's value of the mass of Jupiter is employed; for Uranus the elliptic elements of Bouvard are used as the basis, with Leverrier's corrections and perturbations caused by Jupiter and Saturn (*Conn. des Temps* for 1849), and with Peirce's corrections and perturbations arising from the action of Neptune; finally, for Neptune, Peirce's theory and Walker's orbit have been used in the construction of the ephemeris.

Another very useful work is the French *Annuaire*, which contains some valuable articles by Arago, and the *Annuaire de Bruxelles* which, since 1835, has been published yearly under the superintendence of M. Quetelet, director of the observatory of that city.

Finally, we must make mention of the *Comptes Rendus* of the French Institute, which furnishes abstracts of all papers read at the meetings of that body, and contains very many valuable articles by the best French astronomers. This series is, however, too generally known to require more than this passing notice.

We will now proceed to give some account of such modern societies and institutions as have most tended to advance the science of astronomy; and it will be sufficient to advert to two of the most prominent of those connected with England, namely, the *Royal Astronomical Society of London*, and the *British Association for the Advancement of Science*.

The Royal Astronomical Society dates its existence from the year 1820. Previously to this time the greater number of papers relating to English astronomical research were presented to the Royal Society, and many valuable articles appeared from time to time in the *Philosophical Transactions*, particularly those of Sir William Herschel. It was evident, however, that astronomy involved so vast a field of research as to require a totally independent organization. The Astronomical Society, accordingly, was founded; and, at its first meeting in 1821, it enrolled amongst its members every astronomer of reputation in England, and, amongst its associates, several of the most distinguished philosophers of the continent. Amongst its officers at this time were Sir William Herschel (president), and Sir John Herschel, Mr Baily, Mr Babbage, and Dr Pearson; and

History.

amongst its associates were found the names of Arago, Biot, Delambre, Laplace, Bessel, Gauss, Harding, Littrow, Olbers, Schumacher, Zach, and Piazzi—in fact, every continental astronomer of acknowledged reputation.

From the first establishment of the Society, its serial publications were two, namely, the *Memoirs*, published from time to time in quarto volumes, and the *Monthly Notices*. In the former are printed papers, either practical or theoretical, having more than a temporary interest, and declared by a committee appointed for the purpose to be worthy of a permanent record; in the latter are given abstracts of all papers presented to the Society, and a full account of all the proceedings at the monthly meetings. At the present time the *Monthly Notices* take rather a wider range; and omitting such observations as are sure to appear in the *Nachrichten*, they supply abstracts and reviews of all astronomical papers or books whatever, which appear either at home or abroad.

The quarto volumes of the *Memoirs*, now twenty-one in number, are exceedingly rich in the contributions of both English and foreign astronomers. Amongst the most valuable papers contained in them may be mentioned some of the contributions of the late Mr Francis Baily, including his compiled catalogue of stars (commonly called the *Catalogue of the Astronomical Society*); his *Report on the Pendulum Experiments made by Captain Foster;* his edition of the catalogues of Ptolemy, Ulugh Beigh, Tycho Brahe, and Hevelius; and finally, his account of his repetition of the Cavendish experiment for determining the mean density of the earth.

The volumes contain also many valuable papers by Sir John Herschel, Mr Airy, and many other distinguished astronomers, which it would be invidious to particularize.

The *Monthly Notices* communicate to the Society generally every astronomical circumstance of interest; they give the correspondence of its members with foreign associates, and accounts of every class of observations communicated to the Society by its fellows or correspondents; and, in fact, perform all the offices of a monthly journal for the science in relation to the English scientific public.

In the annual report of the council to the Society, a good retrospect is taken of the events of the past year; and from the date of its establishment, its pages contain perhaps the best materials extant for a history of the science, including memoirs and accounts of all eminent astronomers who have died in the interval.

At the end of 1830 the society obtained a royal charter of incorporation, enabling them to amass property, to receive bequests, and to insure its perpetuity; and, generally, to augment its consideration and sphere of usefulness. It has taken ever since the title of the Royal Astronomical Society of London, and has the sovereign for its patron.

Of all the societies for the advancement of separate physical sciences which have branched off from the Royal Society, as the Astronomical Society was one of the first, so it has been probably the most practically useful. Its reputation has been constantly increasing; and the influence of its works, and of the operations set on foot through its agency, extends to every part of Europe and America, and has produced a marked effect in every department of the science.

The British Association for the Advancement of Science has been also very instrumental in assisting the progress of Astronomy. With its general objects and constitution our present subject is not concerned; and we shall confine ourselves to a mention of such astronomical books or works as it has been the means of producing. The Association was indebted for its existence chiefly to the exertions of the *Yorkshire Philosophical Society*, and to the convictions of that body of the utility of organizing the efforts of the various societies for the advancement of science existing in London as well as in the provincial towns of our empire.

The first meeting of the Association was held at York in September 1831; and, as concerns the science under consideration, a report on the state and progress of physical and practical astronomy was requested from Professor Airy for the meeting of the next year to be held at Oxford. Mr Lubbock was also requested to furnish a report "on the means which we possess, or which we want, for forming accurate tables for calculating the time and height of high water at a given place."

History.

The former of these reports, which is a most valuable synopsis of the progress of astronomy from the beginning of the present century to the date of the report, is printed in the first volume of the Reports of the Association.

The astronomical works of greatest importance, performed by aid of the funds, and under the auspices of the Association, are, 1st, The compiled catalogue of 8377 stars, formed under the direction of Mr Baily, with an elaborate introduction written by that astronomer; 2dly, the catalogue of Lalande, containing more than 40,000 stars, formed by the reduction of the observations of the *Histoire Céleste*; and 3dly, the catalogue derived from Lacaille's *Southern Observations*, containing 9766 stars.

The formation of the above-mentioned catalogues, and the reduction of the ancient observations of Lalande and Lacaille, necessary thereto, are works of that magnitude and importance which only such a society could have undertaken, and which rank amongst the most valuable boons to astronomy in the present century.

We come now to the most important class of institutions tending to promote astronomy, namely, the great *Observatories*, of which almost every country in the civilized world has one or more. Our limits oblige us to confine ourselves chiefly to those observatories which have produced in the present century important changes and advances in the science, merely adverting to the others by way of reference.

Of observatories of the first class are those of Greenwich, Cambridge, Oxford, Edinburgh, and the Cape of Good Hope, in the British dominions; of Dorpat and Pulkowa in Russia; of Berlin and Königsberg in Prussia; and, finally, the observatory of Paris; and of these we shall give short notices.

The *Observatory of Greenwich* is sufficiently well known to prevent any necessity for dwelling upon its early history; and our remarks will be confined to its operations since the accession of the present Astronomer-Royal, Mr Airy, near the end of the year 1835. At that time the instruments consisted mainly of a 10-foot transit instrument, and a 6-foot mural circle, both by Troughton; of a 5-foot equatorially-mounted telescope by Ramsden, and of another small equatorial (since dismounted) by Sisson. There was also a gigantic 25-foot zenith tube by Troughton, which has been since dismounted. The working staff of the establishment consisted, in addition to the Astronomer-Royal and the first assistant (the Rev. R. Main), of five subordinate assistants. Since that time very little alteration has taken place in the staff or organization of the establishment, excepting in the employment of additional computers.

In 1840 magnetical and meteorological observations were commenced in an observatory built for the purpose, of which the superintendence was given to Mr Glaisher, one of the assistants in the astronomical department, and observations have been carried on up to the present time; for the last few years they have been made, however, by a photographical process.

The principal changes and additions to the instruments are the following:—

In 1838 was erected an equatorial instrument, of which the telescope has an object-glass of 7 inches diameter, with a focal length of 8 feet, presented by the Rev. R. Sheepshanks. This instrument has a clockwork movement attached, and many valuable observations have been made with it.

In 1847 was erected a very massive altitude and azimuth instrument, constructed by the Astronomer-Royal on peculiar principles of solidity and strength, for the purpose of making extra-meridional observations of the moon with as great accuracy as those usually made on the meridian, and thus securing generally a far greater number of observations in each lunation, as well as a good supply of observations near the conjunctions, which was totally impracticable before. Every object intended by this instrument has been amply realized. The observations made with it are of equal excellence with those made on the meridian, and they are more than double in number;—in addition, observations have been made occasionally within thirty hours, and frequently within two days, of the time of conjunction on either side.

History.

In 1850 was erected a large *transit circle*, intended to replace the transit instrument and mural circle then in use. This instrument, which was brought into use early in 1851, occupies very nearly the same position as the mural circle formerly in use, its centre being 6 feet S. of the point corresponding to the centre of that instrument. It is also 20 feet E. of the position occupied by the transit instrument. The focal length of the telescope is 12 feet, and the diameter of the object-glass is 8 inches. In connexion with the instrument are two collimating telescopes of 5 feet focal length, one to the N. and the other to the S. of it. For the determination of the zenith-point, observations are made daily of the coincidence of the horizontal wire with its image reflected in mercury, as well as observations of stars by reflexion. The pivots of the axis are 6 inches in diameter, and the instrument is of very great weight and solidity. It is found that ordinarily as many observations can be made with it by one observer as could be made formerly with the transit instrument and mural circle by the employment of two observers; and that they are of unexceptionable excellence.

We must not here omit to mention the system of galvanic communications now in operation. Wires were laid in the spring of 1852, connecting the observatory with the general system of wires of the South-Eastern Railway Company; and since that time a communication has also been made between the wires of the Electric Telegraph Company crossing Blackheath, and the observatory. It is thus enabled to communicate at pleasure (with the concurrence of the companies above named) with any place to which the wires of these companies extend; and successful experiments have already been made for the determination of the longitudes of the observatories of Cambridge and Edinburgh. From the observatory hourly time-signals are transmitted to the stations of the South-Eastern Railway at London Bridge, Tunbridge, Deal, and Dover. For the transmission of these signals the circuit is closed by means of a clock whose maintaining power is galvanic; and by a combination of the same agency and of electro-magnets fixed near the trigger which drops the Greenwich time-ball at 1 o'clock, the ball is dropped by electro-magnetic power. A ball erected at the office of the Electric Telegraph Company in the Strand is also dropped by the same agency, the wires in connexion with its electro-magnets being included in the circuit. Several sympathetic clocks in the observatory beat in coincidence with the *motor-clock*, especially one of which the dial is exposed to the public; and it is intended that ultimately clocks at London Bridge and other railway stations shall be put in connexion.

To the Greenwich Observatory, and to the untiring labours of its present eminent director, are due some of the most important works of modern astronomy. The ordinary production of each year is a thick 4to volume, averaging from 600 to 700 pages. The star-observations, as far as the year 1847, are incorporated in a catalogue of 2156 stars, named the *Twelve Year Catalogue*. Recently observations have been made of all stars down to the fourth magnitude included in the British Association catalogue, and visible at Greenwich; a copious list has been observed for the determination of clock error, and is now in ordinary use in addition to the list of the *Nautical Almanac;* and finally, a good list of circumpolar stars has been observed for the determination of the azimuthal errors of the transit instrument.

A great many comets have been in former years well observed with the equatorials, as well as a small catalogue of double stars. The bright planets have all been well measured, and, in particular, the ellipticity of the planet Saturn has been determined by means of measures made with a double-image micrometer, in a paper by Mr Main, printed in the eleventh volume of the *Memoirs of the Royal Astronomical Society*.

Besides the ordinary work of the observatory, many great works have been undertaken and completed by the Astronomer-Royal. Of these the most important is the reduction of the ancient lunar and planetary observations made at Greenwich by his predecessors, beginning with Bradley. Both these works are of a most important character; and the former, immediately after its publication, was instrumental in detecting a remarkable inequality of the lunar orbit, depending upon the action of Venus, on the results being put into the hands of M. Hansen. The ancient lunar and planetary observations form three thick quarto volumes.

Another work of considerable importance was the determination, in 1845, of a large arc of parallel on the earth's surface, by means of chronometrical determinations of the longitudes of stations at Kingstown (Dublin), and the island of Valentia on the west coast of Ireland.

The Observatory of Cambridge.—The building was completed in 1824, and the first director of the observatory was Professor Woodhouse. Professor Airy succeeded him in 1828, and continued till the autumn of 1835, when he became Astronomer-Royal. He was succeeded by Professor Challis, the present director.

The observatory was at first furnished only with a 10-foot transit instrument by Dollond. To this was added in 1832 an 8-foot mural circle by Troughton and Simms, and a 5-foot equatorial by Jones. Finally, the Northumberland equatorial (so called from the title of its donor the Duke of Northumberland) was erected under the direction of Mr Airy in 1838. The telescope of this fine instrument is of nearly 20 feet focal length, and the clear aperture of its object-glass is $11\frac{1}{2}$ inches. It is mounted with its telescope in the plane of the polar axis, which is supported above and below by pivots resting in Ys.

At the accession of Professor Airy, he introduced a very important principle, vigorously followed by himself up to the present time, and now imitated in the greater number of British observatories, namely that of thoroughly reducing every observation before its publication. The elements of reduction are uniform throughout; and, these being explicitly stated in the introduction to each volume of observations, it is comparatively easy to compare the results with those of any other set of reduced observations, even if the elements be somewhat different, by making the requisite alterations.

Mr Airy, while at Cambridge, introduced an important alteration in the use of the mural circle, by observing the reflected as well as the direct image of a star at the same transit, and thus determining the zenith point.

He also introduced the practice of observing the planets when at a considerable distance from opposition on either side. By this means errors in the orbits were rendered capable of detection, for which no data existed previously, especially such as depend upon an error in the radius-vector.

The results of Mr Airy's star-observations, made at Cambridge, were afterwards collected by himself, and published in a catalogue of 726 stars, named the *First Cambridge Catalogue*.

The planetary observations were also grouped by him, and the normal results published in various papers of the *Memoirs of the Royal Astronomical Society*.

The activity of the observatory has continued undiminished to the present time; but, on account of the erection of the Northumberland Equatorial, the chief subjects for observation have become necessarily different. This instrument has been employed systematically for several years in observations of double stars, and of the small planets which recent discoveries have rendered so numerous. Our readers will also remember, and we shall have farther occasion to notice in our history of the planet Neptune (*Supplement to Part II.*), the active part taken by Professor Challis in the search for that planet, and the fact that it was twice actually observed by him before Galle's discovery, although it was not recognised till after the discovery.

The Radcliffe Observatory at Oxford.—This observatory was erected about the year 1774. Its directors have been successively Dr Hornsby, Dr Robertson, Professor Rigaud, and Manuel J. Johnson, Esq., the present director. The observations which have given an honourable distinction to this observatory have been made during the directorship of Mr Johnson, and are inferior to none produced at any establishment with an equal amount of observing force, in number, in accuracy, or in punctuality of publication. They are also published in a reduced state, which adds considerably to their value.

History.

The instruments consist mainly—1*st*, Of a ransit instrument of 8 feet focal length, and 4 inches aperture of object-glass, constructed essentially in 1843 by Simms; 2*dly*, Of a meridian circle of 6 feet in diameter, erected in 1836 by Jones; 3*dly*, Of a fine heliometer erected in 1850, by the Messrs Repsold of Hamburg, the object-glass of which is by Messrs Merz of Munich, and is of $10\frac{1}{2}$ feet focal length and $7\frac{1}{2}$ inches aperture.

Mr Johnson's great work has been, since his accession to the directorship in 1839, the re-observation of the stars in Groombridge's *Circumpolar Catalogue*, and the careful determination of their magnitudes. This, with the aid of only one assistant, he has completed, and is preparing to arrange the collected results in a catalogue.

This work, when completed, will be a great boon to science on many accounts, but especially for the accurate determination of the proper motions of the stars, more than 4000 in number, contained in the catalogue.

Another assistant has recently been added to the establishment, for the working of the heliometer.

Of the observatories in the British dominions, we will next mention that at the *Cape of Good Hope*. This observatory was established by order in council in 1820, at the instigation of the then existing Board of Longitude. The Rev. Fearon Fallows was appointed the astronomer, with a salary of L.600 per annum, and he was to be supplied with an assistant to carry on the observations. He was instructed to make observations of the same kind and in the same manner as those made at Greenwich, so that "the whole might constitute two corresponding series capable of comparison in all their parts."

Mr Fallows arrived at the Cape in August 1821, and after some unavoidable delays, the observatory was erected on a site he had selected between Liesbeck River and Zwart or Salt River. Notwithstanding innumerable disadvantages and annoyances against which he had to struggle, he contrived to observe a catalogue of 273 stars, the reception of which was announced at a meeting of the Board of Longitude in November 1823.

A new clock by Hardy was shipped for him at the end of 1822, and the transit instrument and mural circle intended for the observatory were progressing; but no steps had been taken for the building of the observatory, which was not completed till 1827, and the instruments were not mounted and ready for use till 1829.

The instruments at that time were,—1*st*, A transit instrument by Dollond, of 10 feet focal length, and 5 inches aperture; 2*dly*, a mural circle by Jones, of 6 feet in diameter, which proved a very faulty instrument, and caused most serious annoyance, not only to Mr Fallows, but to other astronomers.

Mr Fallows did not live long after the completion of his observatory, when he might have expected to reap some rewards of his previous labours and anxieties. He died on the 25th July 1831, deeply regretted in all scientific circles in England.

Mr Henderson succeeded Mr Fallows at the Cape, but resigned his appointment in 1833. During his brief directorship, however, he materially advanced the reputation of the observatory. The bright double star α Centauri was found to have a considerable proper motion; and this induced him to make a series of observations for the purpose of detecting its parallax, which he ultimately found to be about one second of space. This result has since been confirmed by his successor, Mr Maclear.

Mr Henderson was succeeded by the present director, Mr Maclear, who had for his assistant, Mr C. Piazzi Smyth, the present Astronomer-Royal of Scotland. The observations of Mr Maclear for 1834 were published in 4to in 1840, but only one additional volume has appeared since. He has, however, been actively employed, and many valuable results have been printed in the *Memoirs of the Royal Astronomical Society*, of which we may mention, in particular, the details relating to the measurement of Lacaille's arc of meridian.

Two more assistants have at different times been added to the staff, and more recently a magnetical and meteorological observatory has been added, provided with one additional assistant.

A good equatorial, with clock movement, of which the telescope is of $8\frac{1}{2}$ feet focal length, and 6·9 inches aperture, was erected in 1849; and a large transit circle similar to that at Greenwich, and intended to supersede the present meridian instruments, is in course of construction.

Mr Maclear is at present engaged in observing approximately, with the mural circle, all the stars of the catalogue of the British Association which are visible at the Cape, and has already cleared up a great many errors and inconsistencies in Lacaille's observations.

The Royal Observatory of Edinburgh.—This observatory is situated on the Calton Hill of Edinburgh. It had its origin in an astronomical institution, whose members built on the Calton Hill a small observatory, and placed it in the charge of the Professor of Astronomy and Natural Philosophy, Dr Wallace. At this time there existed a sinecure Professorship of Practical Astronomy; but, at the death in 1828 of Dr Blair, who had for some time occupied the chair, the government declined to fill up the vacancy immediately. The office remained vacant from 1828 till 1834; when an agreement was made between the government and the members of the Institution, whereby the latter gave up to the university the use of the observatory on the Calton Hill, which the former undertook to convert into a public establishment, by furnishing it with suitable instruments, and making provision for an observer and an assistant. It was then resolved to fill up the office of Professor of Practical Astronomy, and to combine with it the direction and superintendence of the observatory; and this arrangement has continued till the present time, though until lately no attempt was made to form a class of practical astronomy.

Mr Henderson, on resigning his appointment at the Cape, was appointed to the office, and continued to fill it until his death, which took place in 1844. Under his able directorship, and by his unremitting labours, the Edinburgh Observatory immediately took its place amongst the best institutions of the kind. The observations made with the transit instrument and mural circle rivalled those made at Greenwich in accuracy and in number, taking into account its small establishment; while the director illustrated and extended astronomy generally by a long series of papers on various branches of the science, many of which are of great value, and are reckoned amongst the most valuable contributions of the time. He had considered it an indispensable duty to reduce the observations which he had made at the Cape of Good Hope; and at this he worked diligently as long as his life lasted, and his other duties would permit.

It has been already mentioned that he determined the parallax of α Centauri. By comparison of his observations of the moon made at the Cape with those made in Europe, he established the necessity of a considerable augmentation of the moon's parallax; while, by observations of very low stars, he has produced materials for a new set of refraction tables. Finally, he deduced from his observations a catalogue of the declinations of 172 principal stars, chiefly in the southern hemisphere. Indeed, he seems to have done for his epoch in some degree the same thing which was done by the illustrious Bessel; he redetermined and corrected some of the most important astronomical elements, and his papers remain as models of elegance and accuracy to future inquirers.[1]

At the time of Mr Henderson's death he left five published volumes of observations, namely, those from 1834 to 1839, and a sixth nearly ready for publication. His successor, Professor Piazzi Smyth, took upon himself the charge of reducing the observations of the remaining years up to the time of his decease. This task he has accomplished; and the *Edinburgh Observations* now form an uninterrupted series from 1834 to 1844, printed in ten volumes 4to, and inferior to none yet produced in accuracy or utility.

The principal instruments of the observatory consist of a transit instrument by Repsold and Son of Hamburg; a mural circle by Troughton and Simms; and an altitude and azimuth

[1] For a complete catalogue of his works, see the *Monthly Notices of the Royal Astronomical Society*, vol. vi. p. 190.

instrument by the same artist. The transit telescope is of nearly $8\frac{1}{2}$ feet focal length, and $6\frac{1}{4}$ inches aperture. The 6-foot mural circle is similar to those formerly used at Greenwich.

Since the accession of Professor Smyth, a new arrangement has been made with the government. The town authorities have consented to make over the building to the crown, on condition of the latter taking upon itself the sole charge of defraying the expenses of the establishment, and of providing for its adequate and perpetual maintenance. A general repair of the building and the instruments has since been made, and at the same time a board of visitors was appointed, so as to render the management of the observatory in most respects similar to that of Greenwich.

The *Observatory of Paris* was built by order of Louis XIV. during the years 1668 to 1671. It had for its first directors successively the four Cassinis; namely, the celebrated Dominique Cassini, and after him Jacques Cassini, Cæsar Francois Cassini, or Cassini de Thury, and finally Jean Dominique Cassini, or the Comte de Cassini. For the ancient history of this observatory, the reader may refer to Delambre's *Astronomie au dix-huitième siecle*, p. 311; we have space only for a few remarks on its modern condition.

The instruments have consisted for some years chiefly of a transit instrument by Gambey; of a mural circle, completed by Fortin in 1822, and of another since erected by Gambey; and finally of a good equatorial of moderate size by the latter artist.

Several volumes of unreduced observations have recently been published in folio, which give ample evidence of the skill and industry of the observers, but they do not appear to be made on any settled plan, and the introductions defend the principle of publishing them in the unreduced state. Individually, the astronomers of the Paris Observatory have taken a good part in the recent discoveries and rapid progress of the science. Faye, Laugier, and Mauvais have been distinguished by their cometary discoveries, as well as for other valuable works; Leverrier is the famed discoverer of the planet Neptune; and, finally, Villarceau is distinguished for his researches on the orbits of double stars.

For many years the Paris observations were printed in the *Connaissance des Temps*. The observations from 1800 to 1803 are printed in the volumes for 1823, 1824, and 1825. From 1803 to the commencement of 1810, they are printed in the volumes extending from 1808 to 1812.

Afterwards they were printed in two distinct folio volumes, the first of which contains the observations from 1810 to 1819, and the second from 1820 to 1828. Finally, a new series has been published in folio, containing, in ten volumes, the observations from 1837 to 1846.

The *Observatory of Berlin* is of comparatively recent date, but the institution was contemporary with that of the Academy of Sciences, which dates from the commencement of the seventeenth century. Omitting the history of the institution before the erection of the modern building, which is only interesting in connexion with the publication of the *Jahrbuch* under Bode, and which may be found in Encke's introduction to the first volume of his observations, we shall confine ourselves to a short description of the modern observatory.

Encke succeeded Bode about 1822, but it was not till 1828 that, on the representations of Humboldt, measures were taken for the erection of a suitable observatory, of which the foundation-stone was laid in 1832.

The building is situated in the Lindenstrasse, near the north boundary of the city wall, and the instruments are placed in apartments above the ground floor, on solid piers of masonry carried up from the foundation. It contains—

1. A large refracting telescope by Fraunhofer, mounted equatorially, of the same dimensions with that at Dorpat, the mounting being similar to that of the Königsberg heliometer.

2. A $3\frac{1}{2}$-feet meridian circle by Pistor, the telescope of which is of 5 feet focal length, and of $5\frac{1}{4}$ inches aperture.

3. A $3\frac{1}{2}$-feet transit instrument by Dollond, placed in the prime vertical.

4. A heliometer of 42 inches focal length, by Utzschneider and Fraunhofer, mounted equatorially.

There are as usual several smaller instruments, and a magnetical observatory has been added to the establishment.

Three folio volumes of observations, commencing with 1838, have been published.

The importance of this observatory is chiefly due to the labours of Professor Encke. We have already mentioned his researches on the comet of 1680, and he is still more celebrated for those on the comet bearing his name, which have been the means of bringing into evidence the existence of a very thin resisting medium pervading the planetary spaces. Recently he has published a very ingenious method of calculating the disturbances of the small planets. This memoir has been translated by Mr Airy, and is published as an appendix to the *Nautical Almanac* for 1856.

Dr Galle, who was till lately attached to the observatory, has also added to its reputation by the discovery of two comets, and still more by the discovery of the planet Neptune, on the first evening of his search, near the position indicated by Leverrier.

The *Observatory of Königsberg* was finished in 1813, and none has contributed more during the present century to the improvement of every branch of astronomy than this observatory, under the direction of Bessel.

It is situated on the summit of a hill on the N.W. of the city, and at first was but moderately equipped with instruments. In 1820 there was added a good meridian circle by Reichenbach, and with this instrument were made those observations of small stars lying between 45° N. declination and 15° S. declination, known by the name of Bessel's Zones. These observations have been recently reduced (as far as 15° N. declination) by Dr Weisse, and the resulting catalogue is printed in 4to.

In 1829 was erected the celebrated heliometer by Fraunhofer, which is described in the *Memoirs of the Royal Astronomical Society*, vol. xii. The most celebrated work performed with it by Bessel, was the detection of the parallax of the binary star 61 Cygni. It has been since used by Wichmann in the attempt to detect the parallax of the star No. 1830 of Groombridge's catalogue.

In 1841, a new and improved meridian circle, by the Brothers Repsold of Hamburg, was erected, and in the use of it Bessel introduced the practice of obtaining the nadir point by means of observations of the coincidence of the direct and reflected images of the horizontal wire of the telescope.

The fame of this observatory is so intimately connected with that of Bessel, that a full account of the works performed in it would be but a record of part of the life of that great man, and for this we would refer the reader to the *Notices of the Astronomical Society*.

Our limits oblige us to be brief in our accounts of the Russian observatories at Dorpat and Pulkowa, which have both attained the highest possible distinction through the labours of Struve.

The *Observatory of Dorpat* was built about 1811, and in 1813 Struve was appointed to it. For some time its chief instrument was an 8-feet transit instrument; but in 1822 a large meridian circle by Reichenbach was added; and at that time Struve began those researches in sidereal astronomy which have rendered him so famous.

In 1824 was added the great Fraunhofer refractor, of which a particular description, accompanied with plates, is given in Part iv. of this article.

The results of Struve's labours with regard to double stars are contained in a large folio volume, entitled, *Stellarum duplicium et multiplicium mensuræ micrometricæ per magnum Fraunhoferi tubum, annis à 1824 ad 1837 in Speculâ Dorpatensi*, Petropoli, 1837. This volume is accompanied by a smaller work of reference, entitled *Catalogus Novus Stellarum Duplicium*.

Very recently, M. Struve has published another large folio, giving the mean places for 1830 of the stars observed at Dorpat. The title is *Stellarum fixarum imprimis duplicium et multiplicium positiones mediæ pro epocha 1830, deductæ ex observationibus meridianis, annis 1822 ad 1843, in Speculâ Dorpatensi institutis.*

History.

M. Struve was appointed in 1839 to the new observatory to be erected at Pulkowa, and was succeeded by M. Mädler, who has well sustained the reputation of the observatory of Dorpat.

The foundation-stone of the *Observatory of Pulkowa* was laid in 1835; and in the autumn of 1839 this best endowed and most perfectly organized of all European observatories was completed and in working order. We must be content to give only a few details concerning this admirable institution.

The instruments are the following:—

1. A large transit instrument by Ertel, with provision for reversing the position of the eye-piece and object-glass, and with a collimating mark placed on a pier to the S. of the instrument.

2. A large vertical circle by Ertel, in construction similar to an astronomical theodolite. The focal length of the telescope is 77 inches, and the diameter of the object-glass very nearly 6 inches. With this instrument were made M. Peters's observations for determining the parallax of certain stars, of which the results are given in his paper, *Récherches sur la Parallaxe des Etoiles Fixes*, printed in the Transactions of the Petersburg Academy.

3. A meridian circle by Repsold, with all the improvements suggested by M. Struve's experience. The focal length of the telescope is nearly 7 feet, and the aperture of the object-glass 6 inches. "This instrument is designed," says M. Struve, "for the collection of a great mass of observations to serve for the construction of a vast catalogue of stars."

4. A large transit instrument by Repsold, placed in the prime vertical. The telescope is of 7½ feet focal length, and 6½ inches aperture of object-glass. With this instrument M. Struve made his observations for determining the value of the constant of the aberration of light discussed in his paper, *Sur la Coefficient de l'Aberration des Etoiles Fixes*, 1843.

5. The great refracting telescope by Merz and Mahler, of which the focal length is 22½ feet, and the clear aperture of the object-glass 15 inches. It is mounted equatorially according to the usual method applied to foreign telescopes. It has been used with great effect by M. Otto Struve, son of the director, on the system of Saturn and on other objects. A similar telescope has since been erected at the observatory of Harvard College, Cambridge, Massachusetts, which has added to astronomical discovery.

6. A heliometer by Merz and Mahler, of which the focal length is 10 feet, and the aperture of the object-glass is 7½ inches.

These are the grand instruments of the establishment, which is also liberally supplied with smaller instruments of every kind. There is also a very fine library attached to the establishment, of which the foundation is that of Olbers, purchased after his decease.

Connected with the observatory are workshops for making the requisite repairs and alterations in the instruments, and to these are attached mechanists and carpenters superintended by proper officers.

Besides the persons on the ordinary staff of the establishment, several others are ordinarily attached, either for instruction or for the carrying on of special works, or in connexion with geodetical or geographical operations. To give some idea of the extent of this noble institution, M. Struve estimated that in 1844 there were no fewer than 103 persons (including the wives and families of the persons employed) residing within its boundaries.

We are obliged to conclude this short account of a few of the leading observatories of Europe, without mention of many others of very considerable importance in the history of astronomy. We should have been glad to have given some detailed notices of that of Bonn, including the labours of Argelander, and of Hamburgh, including those of Rumker. The observatories of Cambridge and Washington in the United States are also of great importance; as well as the private observatories of Mr Bishop, Mr Lassell, Lord Rosse, and Mr Cooper. The preceding sketch may however suffice to show the great activity that during the present century has pervaded every branch of astronomy, and to guide the student in some measure to the sources of astronomical knowledge relating to the present epoch.

Works on the history of astronomy.

The following works may be consulted on the history of astronomy:—Riccioli, *Almagestum Novum*, Bononiæ, 1653, 2 vols. folio; Sherburn's *Translation of the Astronomicon of Manilius*, London, 1675; Weidler, *Programma de Veteris et Novæ Astronomiæ Discrimine*, Wittembergæ, 1720; Souciet, *Observationes Mathematiques, Astronomiques*, &c., 1729, 2 vols. 4to. The second volume of this work, by Gaubil, contains a history of the Chinese Astronony, with Dissertations. Weidler, *Historia Astronomiæ*, Wittemb. 1741; Idem, *Commentatio de Mechanica Astronomica Medii Ævi*, 1742; Long's *Astronomy*, London, 1742; Costard's *Letter to Martin Folkes concerning the Rise and Progress of Astronomy among the Ancients*, London, 1746; Foulques' *History of Astronomy*, London, 1746; Heathcote, *Historia Astronomiæ*, Cantab. 1747, 8vo; Esteve, *Histoire Générale et Particulière de l'Astronomie*, Paris, 1755, 3 vols. 12mo; Goguet, *Origine des Lois, des Arts, et des Sciences*, various editions; Jablonow, *De Astronomiæ Ortu ac Progressu*, &c., Romæ, 1763, 4to; Bailly, *Histoire de l'Astronomie Ancienne et Moderne*, 1775, 1779, 1782, 4 vols. 4to. This work has been published without the notes and calculations in 2 vols. 8vo, Paris, 1805. Gentil, *Sur l'Astronomie des Indiens*, *Hist. Acad.*, Paris, 1772; Gaubil, *Histoire de l'Astron. Chinoise*, in the *Lettres Edifiantes et Curieuses*, tom. xxvi.; Bailly, *Traité de l'Astr. Indienne*, Paris, 1787, 4to; Playfair's *Remarks on the Astronomy of the Brahmins*, in the *Edinburgh Transactions*, republished in the 3d volume of his *Works*; *Asiatic Researches*, vols. ii., vi., viii.; Adam Smith's *Fragment on the History of Astronomy*; Lalande, *Astronomie*, Paris, 1792, 3 vols. 4to; Idem, *Bibliographie Astronomique, avec l'Histoire de l'Astronomie depuis* 1781 *jusques à* 1802; Vince's *Astronomy*, vol. ii., Cambridge, 1799; Kaestner, *Geschichte der Mathematik*, Göttingen, 1796; Schaubach, *Geschichte der Griechischen Astron. bis auf Eratosthenes*, Göttingen, 1802, 8vo; Montucla, *Histoire des Mathématiques*, Paris, an 7, an 10 (1802), 2d edit. 4 vols. 4to; Laplace, *Exposition du Système du Monde*, and Pond's *Translation* of the same work; Small's *History of the Discoveries of Kepler*, 1803; Bossut, *Histoire Générale des Mathématiques*, Paris, 1810, 2 vols. 8vo; Voiron, *Histoire de l'Astronomie depuis* 1781 *jusques à* 1811, Paris, 1811, 8vo, a continuation of Bailly; Delambre, *Histoire de l'Astronomie Ancienne*, Paris, 1817, 2 vols. 4to; Idem, *Histoire de l'Astronomie du Moyen Age*, 1819, 4to; Idem, *Histoire de l'Astronomie Moderne*, 1821, 2 vols. 4to; Idem, *Histoire de l'Astronomie du xviii. Siècle*, 1827, 4to. These six volumes of Delambre's *Histoire* contain copious extracts of all the principal works which have been published on the subject of astronomy, interspersed with much enlightened criticism; *Geschichte der Astronomie*, von Dr G. A. Jahn, Leipzig, 1844, 2 vols.; Airy's *Report on Astronomy* in *British Association Report* for 1832, vol. i.; Grant's *History of Physical Astronomy*, 1852, 8vo.
